with such lesions, and experience teaches us that the total fat-content of the stools, made up of fats, fatty acids, and soaps, affords a safer guide. Better still is the information supplied by the far more laborious estimation of the proportion of the fat taken in the food which is lost in the fæces. When, in addition, there is a conspicuous failure to split fats the evidence of a lesion of the pancreas is so much the more cogent. In the stools of a healthy man some 75 per cent. of the fat is in the split form, whereas some patients with pancreatic disease pass as little as 20 per cent. in the forms of fatty acids and soaps. The great diagnostic significance of true steatorrhœa arise from the fact that it indicates not only an excess of fats in the stools but also an undue proportion of neutral fat.

In cases with no gross steatorrhœa the microscope may show abundant fat globules and many acicular crystals of fatty acids. Moreover, the large bulk of the fatty stools may arrest attention, and in some cases they are justly described as elephantine.

The jaundice, which is so often associated with obstruction of the pancreatic duct, obscures, to some extent, the indications afforded by the estimation of the fæcal fats, for the mere absence of bile from the intestine causes a great impairment of fat absorption; but even when the pancreatic duct alone is blocked widely divergent results are obtained in different cases. Moreover, in the majority of cases of disease of the pancreas there is no blockage of the duct, and the impairment of secretion results from damage to the glandular tissue, and is less in degree. A patient with grave disease of the pancreas may pass stools with normal fat-content, and this is true even of some cases in which the duct is obstructed, probably because the duct of Santorini remains patent and provides an emergency outlet.

Even when jaundice is present a proportion of fats in the dried fæces exceeding 40 or 50 per cent. is strongly suggestive of a pancreas lesion, and in some cases there is a percentage of 80 or more.

L. Zoja[17] lays stress upon an unduly low proportion of soaps as indicative of pancreatic disease, presumably from a deficient supply of alkali in the intestine, but our own experience and that of others leads us to attach little importance to this sign.

Fat Excretion.

Oskar Gross,[18] who made a very complete study of the fat excretion of two patients with indubitable disease of the pancreas, found that in one case the percentage of the food-fat lost in the fæces remained constant, in spite of wide variations in the amounts in the diet, and Hurtley and I found the same to be true for our case of congenital steatorrhœa; but in Gross's second case, and in that investigated by Spriggs and Leigh,[19] the loss of fat became much greater when the fat in the diet was increased. The last-named observers suggest that the constant percentage loss may only hold good for cases in which the patient's nutrition remains good. It is a remarkable phenomenon and one not easily explained, but upon which future work may throw light.

It will be seen from what has gone before that a patient whose pancreas is diseased may pass excess of neutral fats in his motions, or a great excess of fats, fatty acids and soaps, without any undue proportion of neutral fat. Lastly, a lesion of the pancreas can by no means be excluded on the ground that the stools contain no excess of fatty substances.

Winternitz has introduced a st of the efficienc of the pancreas in dealing with fats. Half gramme of iodo-behenic acid or the drug sajodi which is its calcium salt, is given by the mouth and iodide is looked for in the urine. The sajodi is only broken up when it comes under the influence of the pancreatic juice, and by it only i presence of bile. On this account the test is no applicable when the bile-duct is completel obstructed. When there is no jaundice failure t find iodide in the urine suggests that the lipolyti action of the pancreas is in abeyance.

When, in addition to impaired splitting or utilisa tion of fats, there is obvious failure of protei digestion the evidence of a pancreatic lesion i well-nigh conclusive. There are many ways i which such failure may be detected, but th simplest of all is at the same time the most con vincing. A patient with severe pancreatic diseas will, as a rule, pass in his fæces large numbers o muscle fibres, derived from the meat which he eats undigested and with their striæ clearly visibl under the microscope. He may also pass particle of undigested tissue, and Albu[20] recommends calf' thymus as an article of diet the structure of which is easily recognised in the stools. For thi phenomenon Ehrmann suggested the nam creatorrhœa, by which it is generally called and, although the term invites criticism, it is no easy to invent a better.

Creatorrhœa.

Creatorrhœa, although it may accompany profus diarrhœa from any cause, is hardly inferior to fatt stools in diagnostic value, and it has the advantag that it is not affected by blocking of the bile-duct In a case with jaundice, in which the indication afforded by the fæcal fat are not unequivocal, th discovery of undigested striped muscle fibres i the stools may help materially to clench an otherwise doubtful diagnosis.

Cases are met with in which the syndrome steatorrhœa-creatorrhœa persists for years, in a patient who otherwise enjoys moderately good health, who leads an active life and exhibits no other gross sign of disease. Some such patients have been found to have the duct blocked with calculi and the structure of the gland destroyed and yet may never have exhibited glycosuria. In these cases the more elaborate tests will, as a rule, afford additional evidence of disease of the pancreas.

Excessive excretion of nitrogen in the stools, and a consequent inordinate loss of nitrogen as determined by metabolism investigations, affords additional evidence of impairment of protein utilisation, but other ferments besides trypsin take part in this work, and azotorrhœa, so-called, is far less distinctive than the escape of striped muscle fibres and nuclei. Moreover, the fatty stools of a patient with pancreatic disease offer a far from ideal material for Kjeldahl estimations.

Tests of Tryptic Digestion.

The majority of the pancreatic tests are concerned with the failure of tryptic digestion. T fall into three main groups of procedures. S of them aim at obtaining a sample of d contents for examination; others rely upon despatch of messengers along the alimentary and the examination of the stools or other for evidence as to what has happened to their transit; and yet others upon estimation the tryptic action of the fæces.

The oil-breakfast test relies upon the fact that under its influence some of the contents of the duodenum are regurgitated into the stomach, and may be found in the test meal when it is siphoned off. The technique of the test is comparatively simple, and its results are, as a rule, instructive, but the swallowing of a large dose of olive oil (2 oz.) with a test meal upon an empty stomach, and its subsequent withdrawal, is a proceeding which has little attraction for the British patient. It has been clearly shown that it is possible to obtain a sample of the secretion in the duodenum, either by means of a suitably constructed duodenal sound or, better still, by Einhorn's ingenious device of a small metal capsule cased in gelatin and attached to a string or to an indiarubber tube. The capsule is swallowed and is passed on into the duodenum by gastric peristalsis. It is well to check its progress by X ray examination. By this means as much as 5–10 c.cm. of duodenal juice may be obtained in favourable cases and its tryptic tivity tested. I have no experience of these ethods, and therefore am not in a position to dge of the value of the indications which they ford, nor of the degree of discomfort to the patient hich their application may entail. It is obvious at there are possibilities of fallacy, and that, hereas the finding of trypsin in the juice affords sitive evidence that pancreatic secretion is tering the duodenum, the failure to find it in e fluid obtained is far less conclusive as evidence inefficiency of the gland.

Of methods which test the tryptic power of the æces that of Oskar Gross is most often employed. t is based upon the digestion of casein by an kaline extract of the fæcal material. Failure to digest casein offers strong evidence of pancreatic nefficiency, but, seeing that other ferments in æces can act like trypsin, a positive outcome of the est, unless very pronounced, has less value.

What may be called the messenger tests are of several kinds. Thus Sahli administered capsules of gelatin hardened by formalin, and enclosing a drug easily detected in the urine or saliva. Provided that the capsule is well made it is only amenable to tryptic digestion, and escape of the drug is taken to indicate tryptic activity; but a negative finding is far from conclusive. The capsule may resist tryptic digestion, especially if its journey along the alimentary canal be unduly rapid. It is only necessary to mention Schmidt's beef cube test, and Kashiwado's in which stained nuclei from the calf's thymus are swallowed, mixed with lycopodium granules, the latter to serve as indicators of the part of the fæces to be searched. Sladden, who tried this test on several of my patients, obtained no very encouraging results, and compares the search in the bulky fæces of a patient with pancreatic disease to the proverbial hunt for a needle in a haystack. It seems to me preferable to rely rather upon such gross phenomena as creatorrhœa and steatorrhœa as indicators of inefficiency of the pancreas, than upon the somewhat uncertain responses of these messenger tests.

Carbohydrate Digestion.

To pass on to the consideration of carbohydrate digestion: It was shown by Wohlgemuth, whose observations have been abundantly confirmed, that diminished output of diastase in the stools, and an increase of that enzyme in the blood and urine, are common phenomena in cases of lesion of the pancreas, and it would seem that we are here dealing with a sort of colourless jaundice, due to an obstructed flow of the pancreatic juice into the intestine, or else to a direct escape of diastase into the blood, comparable to that of lipase, which brings about fat necrosis. But there are indications that the explanation of neither of these events may be so simple. However this may be, the estimation of diastase in the urine affords one of the best and most useful tests of the integrity of the pancreas, and at the same time one of those most easily and rapidly carried out. This last is an important matter when we are dealing with acute conditions, in which delay of surgical interference may greatly lessen the prospect of its success. The diastase and adrenalin mydriasis tests may be carried out within an hour, whilst the patient and the theatre are being prepared for an operation. But the diastase test shares the uncertainty which pertains to pancreas tests in general. Instead of the normal 10 to 20, or even 30, units, to use the accepted measures of the test, a patient with pancreatic disease may excrete in his urine 50, 100, or even 200 units. On the other hand, another patient similarly affected may show a normal diastase excretion. Mackenzie Wallis emphasises the fact that the diastase increase is a temporary incident, most conspicuous in the earlier stages of a case. Repeated examinations at intervals may reveal a quicker or slower decline of the diastase output until normal, or even subnormal, figures are reached. Thus it comes about that whereas a conspicuous excess of diastase in the urine is strongly suggestive of disease of the pancreas, a normal excretion, such as was found by Spriggs and Leigh in their case, in no way excludes even advanced disease of that gland.

Nor must it be forgotten that in many cases of renal disease the power of the kidney to excrete diastase is so seriously impaired that its estimation in the urine is utilised as a test of renal efficiency. This deprives the indications of most of their value, for our purpose, in cases with albuminuria. Again, like Loewi's reaction, the diastase test errs on the side of excessive delicacy. Both tests may give positive answers when, so to speak, the pancreas is merely worried by adjacent disease. Thus, when both these tests yield positive findings, strong evidence, stronger by far than either alone supplies, is afforded that the pancreas is at least concerned in the malady; but, apart from other indications, they are in no way conclusive. Of the two, I attach greater importance to the diastase findings. Undoubtedly the failure of both tests in no way excludes serious pancreatic mischief.

The Evidence of Failure of Internal Secretion of the Pancreas.

There remains to be considered the evidence of failure of internal secretion of the gland. Since the classical researches of von Mehring and Minkowski glycosuria has occupied a foremost place among the signs of pancreatic lesions, but from the clinical standpoint it is far from fulfilling the promise held out by physiological experiments. Whereas it is highly probable that the pancreas is concerned in all cases of glycosuria, save perhaps those in which the proportion of sugar in the blood is below the normal, it may well be that in most cases of diabetes the hyperglycæmia and glycosuria result from a disturbance of the normal balance between the pancreas and other endocrine glands, with the result that its internal secretion is inhibited or overpowered. We know that an excess of thyroid secretion may cause glycosuria although the pancreas be intact, and the same holds true for pituitary secretion and adrenalin.

On the other hand, experiments show that a small residue of pancreatic tissue may avert glycosuria, and it is a matter of common knowledge that the gland may be gravely damaged, and even to all appearance destroyed by disease, and yet the patient may excrete no sugar in his urine. Indeed, it may be said that, except in cases of chronic pancreatitis, glycosuria is an uncommon symptom of pancreatic disease. I am inclined to think that daily observations throughout the illness would reveal the presence of sugar in the urine at times in many more cases than appears at present. In an acute case I have met with it in one single specimen, and never afterwards. In cases of carcinoma of the head of the pancreas glycosuria is less rare than might be expected, seeing how large a part of the gland usually escapes invasion and how little time is afforded for the development of secondary changes. Miraillé[21] found it in 13 out of 50, and Guillon[22] in 20 out of 71 cases.

Speaking generally, the absence of glycosuria affords no argument against the presence of disease of the pancreas, but in not a few cases its presence supplies the crowning evidence in support of a diagnosis based upon other findings. Lastly, even those who attribute all diabetes to disease of this gland will hardly maintain that the presence of glucose in the urine is in itself sufficient evidence of such disease. Even in chronic interstitial pancreatitis glycosuria is by no means always present, and Opie[23] attributes the difference in this respect to differences in the incidence of the lesion, which in some cases involves, and in others spares, the islands of Langerhans.

Short of actual glycosuria, the patient's tolerance for glucose may be so far lowered that quantities of that sugar, far smaller than are required to induce glycosuria in a healthy subject, cause glucose to appear in the urine. Thus tests of sugar tolerance are among the diagnostic means at our disposal, but it must be remembered that almost any disturbance of the balance of the internal secretions leads to an alteration, either a raising or a lowering of glucose tolerance.

Cammidge's reaction, which may be fitly referred to in this place, is a phenomenon of much interest, the further investigation of which may throw light upon important metabolic events. It is undoubtedly connected with pancreatic derangements, and when observed supplies a contribution to the building up of a diagnosis. But it shares he uncertainty of other pancreatic tests, and may il us in cases of severe disease of the gland, specially when the disease has reached an advanced stage. So it is natural that many prefer to employ methods which are less time-absorbing, and less at the mercy of small errors of technique. This test has suffered from the fact that too much has been expected from it, perhaps that too much has been claimed for it; and because it has not proved so decisive as was hoped, its utility has not received the credit which it deserves. Of Cammidge's iodine coefficient method, which is a development of his original test, I have had no experience.

Diagnosis of the Nature of the Lesion.

In this survey of the methods at our disposal for the diagnosis of lesions of the pancreas I have presented to you the separate pieces of a jig-saw puzzle. Only when the several pieces have been fitted together can we form a distinct clinical picture of pancreatic disease. Nor must we forget that when we have determined the seat of a lesion we have attained to only half of a diagnosis. We need to diagnose the nature of the lesion also, and as it happens this is often, in the conditions under discussion, the less difficult problem of the two.

In the endeavour to diagnose the nature of the more common diseases of the pancreas, such as acute pancreatitis, carcinoma, cysts, and chronic interstitial pancreatitis, we rely mainly upon the evidence afforded by physical signs and symptoms. Here clinical experience, when fortified by the experience gained in the post-mortem room, is our best guide, although we may derive no little help from the grouping of the responses of the various tests. Even pancreatic calculi have been diagnosed and removed with success; but it is probable that there will long remain a residuum of cases in which we have reason to believe that the pancreas has been damaged by disease, but in which the nature of the lesion cannot be determined with any degree of accuracy.

In order to illustrate some of these aspects of my subject it will be necessary to place before you brief records of a few characteristic cases, and to indicate the steps by which a diagnosis was arrived at in each instance. The examples chosen were wholly unlike in their general features, and had little in common beyond the fact that in all but one of them the pancreas was, or is, undoubtedly implicated in disease. Each one illustrates some special diagnostic points.

CASE 1.—A man, aged 50 years, a street salesman, was admitted to hospital complaining of abdominal pain. Seven weeks previously he had been thrown from a van, struck his head and abdomen, and was rendered unconscious for a short time. After the accident he suffered from severe pain in his back and vomited each morning. Three days later he returned to work, although he felt very unwell and the vomiting continued. A fortnight before his admission he noticed swelling of the upper part of the abdomen, and was obliged to loosen his belt. Five days later he was seized with a violent pain, of sudden onset, with sweating and collapse. The pain was relieved by hot fomentations. From that date the abdominal swelling increased, the vomiting persisted, his bowels were confined, and he suffered much from thirst. He was brought to the hospital after a second attack of severe abdominal pain. The man's appearance was suggestive of grave illness; his expression was anxious, his skin moist, and there was a slight degree of cyanosis. His temperature was only 99°, his pulse 110, and respirations 24 in the minute. Situated in the upper part of the abdomen, midway between the xiphoid cartilage and the umbilicus, was an ill-defined elongated mass, overlapped in part by the gastric resonance. A band of resonance, an inch and a half wide, separated the mass from the hepatic dullness. The tumour did not move with respiration, and no fluctuation could be made out. The abdomen was somewhat distended, but the muscles were not rigid. There was no fre fluid in the abdominal cavity. The patient complaine of severe pain in the back, across the lumbar regio The mass was very tender, but the greatest tendernes was over the left flank.

It is worthy of note that there was exophthalmos slight degree; von Graefe's sign was pronounced, a he wrinkled his forehead very little when he loc upwards. A well-marked tache could be elicited, there was no tremor of the hands. The physical si and symptoms pointed to a subacute pancreati following the injury to the abdomen, and wh specimen of urine was obtained, and found to con sugar, little doubt remained as to the correctness of diagnosis. My colleague, Mr. Waring, saw the pati with me and concurred, and an operation was deci upon. Meanwhile, Dr. Graham estimated the sugar in the blood at 0·21 per cent.: Loewi's reaction was positive, but not of an extreme degree, and Dr. Mackenzie Wallis found 50 units of diastase in the urine. At the operation the diagnosis was confirmed. The pancreas was explored and drained. The man lived six weeks after the operation. On the third day Moebius's sign was present, and von Graefe's persisted, but all the eye signs disappeared before the end. A second specimen of urine, obtained before the operation, contained no sugar, and none was found at any subsequent examination.

CASE 2.—In March, 1919, a carman, aged 59, was admitted to my wards deeply jaundiced, and with a history of three months' illness. On examination, his liver was found to be greatly enlarged and of smooth surface; the gall-bladder was not palpable. Some enlarged glands were felt in the abdomen. Occult blood was found in the stools, but urobilin was wholly absent; signs which suggested that a malignant growth had occluded the bile-duct. Although the clinical features were so unlike those of a classical case of carcinoma of the head of the pancreas, so well described by Bard and Pic,[21] in that the liver was so large, the gall-bladder was not palpable and the patient was neither emaciated nor unduly feeble, the possibility of such a growth was considered, as also that of a malignant growth originating in the bile-ducts. It soon became evident that wherever the growth started, the pancreas was implicated, and for the following reasons. Adrenalin caused a conspicuous mydriasis on several occasions; the urinary diastase amounted to 125 units; the total fats of the fæces constituted no less than 70 per cent. of the dried material, and many undigested striped muscle fibres were seen in the fæces. A week after his admission sugar appeared in the patient's urine for the first time, and the glycosuria persisted until his death. The average daily output of glucose was about 35 g. The fat content of the fæces, which was far greater than the jaundice could explain, increased as time went on, whereas the urinary diastase fell gradually from 125 to 60, 25, and 30 units, figures scarcely above the normal. The patient died after he had been in hospital two and a half months. At the autopsy carcinoma of the head of the pancreas was found: there were no secondary growths in the greatly enlarged liver, which had completely hidden the gall-bladder, which latter, although greatly distended with bile, had never been palpable during life.

CASE 3.—The next case to which I shall refer could not be subjected to any systematic investigation. A man, age 53, was first seen by me in October, 1910, at the request of his medical attendant, Dr. Robbs. His complaint was that for six months past he had passed oil with his stools, which became solid fat on cooling. In 12 months he had lost a stone of weight. He suffered no pain of any kind. Nothing abnormal could be found on examination of his abdomen; his liver was just palpable; there was neither fullness nor tenderness in the region of the pancreas, and there was no jaundice. His urine contained neither sugar nor albumin.

When I saw the patient again, in June, 1913, he had lost another stone but had developed no fresh symptoms, and his urine was still free of sugar. He was still able to lead an active life. Loewi's test gave no mydriasis, and the urinary diastase did not exceed the normal. Dr. Cammidge examined his urine and fæces in January, 1914, and obtained a positive reaction with his test. The total fat in the dried fæces amounted to 51·2 per cent., and of this only 4 per cent. was in the form of soaps. There was obvious creatorrhœa with many undigested muscle fibres in the stools, and by means of Gross's test casein digestion by fæcal material was found to be very incomplete. Dr. Robbs tells me that now, in 1920, the patient's health is better than for some time past, and he has gained seven pounds of weight during the past six months.

CASE 4.—The last case is that of a Belgian refugee, aged 32, who was admitted to my wards in January, 1915. For three years he had been liable to paroxysmal attacks of pain, referred to the region between the xiphoid cartilage and the umbilicus. During the attacks, which were obviously very severe, the patient assumed a position of opisthotonos, but he never vomited. It was suspected that he might have a pancreatic calculus, but the X rays showed no shadow in that region. Loewi's reaction was conspicuously positive, and the urinary diastase was at first 100 and afterwards 50 units. There was no excess of fat in the stools, no glycosuria, and only 0·12 per cent. of sugar in the blood. Thus the only indications of pancreatic disease were the position of the paroxysmal pain, the excess of diastase in the urine, and the adrenal mydriasis. Our investigation of his symptoms was much hampered by the fact that he spoke only Flemish and a very few words of English.

A month after his admission he passed a large tarry motion. A few days later Mr. Waring performed gastro-jejunostomy. A few days after the operation the patient developed broncho-pneumonia, with maniacal delirium, of which he died. At the autopsy a chronic ulcer was found in the second part of the duodenum, three-quarters of an inch in diameter and adherent to the pancreas and adjacent structures. The note describes the pancreas as normal to the naked eye.

If we review these four cases we notice how widely different were the clinical pictures which they presented. In the first case the diagnosis rested mainly upon the clinical signs and symptoms, but several tests of pancreatic efficiency supported the clinical diagnosis. In the second case, that of carcinoma, the evidence of a lesion of the pancreas rested largely upon disturbances of the external and internal secretion of the gland, but was quite conclusive. The only point in doubt was the primary seat of the growth. Except the intense jaundice the clinical signs did not afford much help.

In the third case the associated steatorrhœa and creatorrhœa leave no doubt that the patient is suffering from a severe pancreatic lesion, and Cammidge's test gives further support to this view. Presumably the duct is obstructed, and the pancreas is the seat of interstitial changes. The absence of pain does not exclude the presence of calculi. The failure of the adrenalin and diastase test in no way invalidates the diagnosis. The case resembles one described by T. J. Walker,[27] of a patient whose steatorrhœa persisted from the age of 62 until his death at the age of 90; whose pancreas was found to be completely obsolete and replaced by fat, and the duct was studded with calculi. In cases in which a like syndrome is presented with glycosuria in addition the patient's health is much more seriously impaired, and the prognosis is far more unfavourable.

In the last case, that of the Belgian, we can hardly escape the conclusion that the disturbance of the pancreas by the adjacent ulcer was the cause of the increase of urinary diastase and of the adrenalin mydriasis.

In a case of bronzed diabetes, which has been described at length elsewhere,[26] we employed several pancreatic tests. Of these, Loewi's test, Schmidt's beef-cube test, and the glycosuria all pointed to implication of the pancreas, whereas Cammidge's test, the estimation of fat in the fæces, and the determination of the tryptic and diastatic activity of the stools gave no indication of damage to that gland. After death the pancreas was found to be fibrotic and loaded with iron-containing pigment.

In the case of congenital steatorrhœa, on the other hand, there was no creatorrhœa, the fæces digested casein; Sahli's capsule test and that of Schmidt, a normal diastase content of the urine, and the absence of adrenalin mydriasis, all tended to acquit the pancreas. Cammidge's test alone, kindly carried out by its author, was found to give a "slightly positive result."

TABLE II.

Case.		Loewi's test.	Fatty stools.	Creatorrhœa.	Casein digestion test.	Sahli's test.	Schmidt's test.	Urinary diastase.	Glycosuria.	Jaundice.	Cammidge's test.
1	Subacute pancreatitis.	+	–	–	–	–	–	+	+	0	–
2	Carcinoma of head of pancreas.	+	+	–	–	–	–	+	+	+	–
3	? Blocked duct. Chronic pancreatitis.	0	++	–	+	–	–	0	0	0	–
4	Duodenal ulcer adherent to head of pancreas.	+	0	0	–	–	–	+	0	0	–
5	Bronzed diabetes. Chronic pancreatitis.	+	0	?	0	–	+	–	+	0	0
6	Congenital steatorrhœa.	0	++	0	0	0	0	0	0	0	?

+ signifies positive. 0 signifies negative.
– signifies not tried. ++ signifies true steatorrhœa.

It will be evident, from all that has gone before, that practically every sign, symptom, or test may fail us at times, and that in each individual case we need to balance the quantity and quality of the evidence for and against a lesion of the pancreas. In a word, we come back to Wardell's statement of 1871. It is still true that "no symptoms are pathognomonic of pancreatic disease; an assemblage of symptoms points to the probability of its lesion." But we have at our disposal a far greater assemblage of symptoms than Wardell had, and in not a few cases the degree of probability is not to be distinguished from certainty.

That is as much as can be expected when we are dealing with a problem, the solution of which rests so largely upon circumstantial, rather than direct, evidence. If we cannot claim for the diagnosis of pancreatic disease the clear cut, direct answers obtained in some other regions of clinical medicine and surgery, we may none the less regard with complacency what has, so far, been accomplished in this field, by the application of physiological discovery at the bedside, by the coöperation of the laboratory and the ward.

RADIOLOGY IN CHRONIC INTESTINAL STASIS.[1]

BY ALFRED C. JORDAN, M.D. CANTAB.,
M.R.C.P. LOND.,
MEDICAL RADIOLOGIST, THE ROYAL CHEST HOSPITAL, LONDON.

WHEN the value of radiology in medicine was recognised its aid was sought in the diagnosis of disorders of the stomach and intestines, and it became necessary to define the normal. At first sight this appeared a simple matter. The passage of an opaque substance through the stomach and bowels of a few healthy subjects was observed, and results recorded. In practice, however, two difficulties presented themselves: (1) The text-books of anatomy represented certain shapes and positions as normal, whereas the X ray pictures showed pronounced differences, notably in regard to the stomach and transverse colon; and (2) it was found that great differences existed in the size and position of organs in people, apparently in perfect health. At Guy's Hospital an investigation was made to determine the normal; the members of the football-team were selected as likely to be ideally healthy men. They were given a bismuth meal, and the observers were astonished to find that in most of them the transverse colon had dropped so low that its middle lay in the pelvis. The observers rashly concluded that the position of the transverse colon was of no significance. This statement no one would make to-day. Recently Professor Arthur Keith invited me to address the Anatomical Society, suggesting as my subject "The Radiology of the Normal Cæcum." Feeling incompetent to instruct or even interest the Anatomical Society on this topic, I asked to be allowed to alter my terms of reference so as to read "The Displaced Cæcum," and to this Professor Keith generously consented. When, however, the day of the meeting came, I found that the title of my paper was that suggested originally, "The Normal Cæcum." I was compelled to state as my opinion that there was no such thing, strictly speaking, as a normal cæcum. If, however, I must admit a form of cæcum to be the normal, then it must be the embryonic cæcum—conical, with the appendix forming a direct continuation of the apex of the cone, and the three longitudinal bands, or tæniæ, arising at the base of the appendix and spaced symmetrically around the circumference of the bowel. As soon as the cæcum begins to fill up with solid fæces—i.e., at birth or soon after—the pressure of its solid contents gives rise to sacculation. The saccules make the cæcum protrude between the tæniæ, forcing them apart. Thus at once the cæcum begins to lose some of its efficiency as an organ of propulsion. The loss of efficiency is slight in ordinary cases, but becomes serious if, in later years, stasis causes exaggerated sacculation of the cæcum.

Effect of Civilisation.

In man the brain has developed so much in the course of thousands of years that its evolution has outstripped the rest of the body, and evolution requires millions of years for the body to adapt itself to the requirements imposed upon it by the rapid development of the mind. Professor Keith has proved to us that in the evolution of the orthograde ap certain parts of the large intestines, flexures, have become partly fixed to e pi l walls, thus enabling them to adapt amse. to the erect posture, while the flexures quite e in the pronograde apes. Sir Arbuthnot ne[2] h shown how the individual, in the course his life me, evolves structures which help him adapt imself to the upright posture and the quirements of his work. The radiological study stasis has taught us: (1) The situations in which these new structures are acquired; (2) the advantages that accrue from them; (3) the disadvantages of these defences, owing to the mechanical troubles and difficulties set up in the passage of the intestinal contents; and (4) the secondary changes that are produced in other organs.

---

[1] Being a special lecture delivered at the West London Post-Graduate College on Feb. 20th, 1920.

The Support of the Viscera and the Beginning of Stasis.

In man the viscera are kept in their place normally by the muscles of the anterior abdominal wall, and in health these muscles retain their tone while the individual is upright. Professor Keith has rightly insisted upon this important truth. The power of these muscles can be dramatically illustrated by observing the effect produced when the intestine is full of bismuth and the flexures are mobile. Lately I examined a young woman in whom, in the upright posture, the flexures dropped into the iliac fossæ. When the abdominal muscles were retracted the flexures shot up to their normal level—a rise of fully 8 in. In young healthy subjects the tone of the abdominal muscles keeps the viscera in their right places without conscious effort.

The adverse cycle which leads ultimately to severe stasis starts in early childhood—nay, in early infancy. Artificial feeding leads to overfilling of the stomach. When the stomach is overfilled it weighs down the transverse colon, the contents of which solidify and stagnate. As Mr. Tyrrell Gray showed in his brilliant Hunterian lecture, the tension thus exerted on the mesentery interferes with peristalsis. In attempting to void the solid fæces, straining occurs, and leads to elongation of the pelvic colon. Thus stasis commences, and pursues its evil course unless remedial measures are taken. Great elongation of the pelvic colon is found very often in the subjects of stasis. It can only be revealed satisfactorily by a barium enema. This is given by means of a douche-can and tube, and a gum-elastic rectal end-piece with a single large terminal aperture. The rectal tube need not be more than 4 to 6 in. long. With the patient lying flat, and the douche-can raised only a foot or two, the fluid runs up readily, filling the entire large bowel within two or three minutes. When stasis exists some fluid enters the small intestine, demonstrating *incompetence* of the ileocæcal valve. To those practitioners who use a long flexible tube for "high" enemata I have to say: (1) It is impossible to pass a long tube through the pelvic colon; an X ray picture shows the tube curled up in the rectum. (2) There is no need to use a long tube, since the fluid runs up freely to the cæcum with a short tube in the rectum.

Visceroptosis and the Rôle of the Mesenteries.

If the abdominal muscles are severely exhausted by prolonged or excessive fatigue they yield to the strain, the muscles relax, and the viscera fall. This occurs in strong, healthy young subjects as the result of sporting competitions, and explains why the members of Guy's football-team were found to have prolapsed colons.

In health, prolonged exertion is required to fatigue the abdominal muscles. In stasis, however, these muscles are depreciated—like every tissue in the body—by the action of the circulating bacterial toxins. In this state the muscles "give out" after a short and moderate exertion. Here we have a good instance of a vicious circle. The study of stasis abounds in instances of vicious circles, which explain many of the difficulties attending the successful treatment of stasis.

When the abdominal muscles fail, the mesenteries act as ligaments, and support the intestines. Professor Keith has shown that the same thing occurs in many joints, notably the shoulder-joint, where the muscles form the chief support of the joint. If the muscles fail through fatigue, the ligaments become the chief supporting structures of the joint. The arch of the foot depends in health on the tonic contraction of the peronei and extensor muscles. If these muscles fail through fatigue the arch of the foot is left at the mercy of the plantar ligaments and the calcaneo-navicular ligament. These ligaments, though strong, yield at last, especially if they are reduced in strength by rheumatism or other disease; flat-foot is the result.

The mesenteries are not suitable to act as ligaments and one of two results follows: Either (1) the mesentery refuses the new function forced upon it, and slips down from its attachment; or (2) the mesentery makes an effort to adapt itself to its new rôle, and becomes thickened where the strain is greatest, with the result that some parts of the bowel are held up at their proper level. In the first case we get the phenomena presented in Glénard's classical description of visceroptosis. In this condition not only do the intestines drop, but the other abdominal viscera, notably the kidneys. The result of the dropping is to force the heavier of the viscera down to the lowest point they can reach—in some cases the true pelvis, where they press upon the pelvic organs and excite symptoms attributable to these organs. Later actual pathological changes are produced in the pelvic organs; in women retroversion of the uterus is a constant accompaniment of general dropping of the abdominal viscera.

Kinks: Their Obstructive Action.

The second result follows in more robust subjects, when nature attempts to prevent the fall of the viscera by the formation of new bands to support them. These bands constitute the kinks and membranes which have been described by Sir Arbuthnot Lane. It is entirely due to his keen observation that the significance of these bands has
been realised. As he puts it, "Th ading microb

are also apt to form attachments to the parietal abdominal wall. The outer side of the ascending colon becomes attached in a similar way. The band with which Sir Arbuthnot Lane's name is especially associated is the ileal kink, which forms at the end of the ileum, either close to the ileo-cæcal entrance or at some point along the last six inches of the small intestine. In some cases the appendix becomes fixed by bands, and constitutes an anchor that holds the cæcum at its proper level. The terminal ileum and the appendix may be supported by one and the same band. Another band, which is frequently found and produces important clinical symptoms, descends from the lower border of the liver in the region of the neck of the gall-bladder, then expands, fan-like, with its lower border attached to the hepatic flexure and the first part of the transverse colon. This band falls in front of the pylorus, and in most cases the pylorus is attached to it, and is anchored by it when the stomach becomes loaded with food. In some cases the band is found to continue below the transverse colon, and may terminate in an ileal kink, or may even descend to the pelvis and become attached to the right ovary. All these bands and kinks can be demonstrated radiologically during the course of a bismuth meal through the alimentary tract. By means of careful fluorescent-screen examinations, both in the recumbent and upright posture, fixed points of the bowel can be ascertained by the range of movement which occurs during respiration, and by means of manual pressure. If an operation follows upon a bismuth examination, the radiologist has a chance of finding out whether he has failed to note an important detail, or whether he has correctly interpreted the shadows that were thrown upon the screen. By this means only can radiological diagnosis be advanced and perfected.

It must not be inferred that bands and kinks produce mechanical obstruction only, for every band or thickening is an irritant focus which sets up spasm, not purely local, but for a considerable distance along the bowel. If there is a kink within 2 inches of the termination of the small intestine, the cæcum, when the subject is upright, hangs down *from* the kinked point of the ileum, and becomes rotated on its axis. This produces torsion of the last 2 inches of the small intestine. Many observers have argued that a kink which is *obstructive* must lead to dilatation and hypertrophy of the bowel proximal to the kink, and that this dilatation and hypertrophy should terminate abruptly at the kink. In reply to this argument we must note: (1) If the kink is a postural one, it is only obstructive while the patient is upright and when the muscles of the anterior abdominal wall are fatigued; and (2) the spasm set up by the kink is a more important factor in producing stasis than the actual obstruc-
kink. Spasm is often most pro-
cæcal entrance, and this leads

pite efforts in every
es the ascending colon follows the cæcum into the pelvis, and drops in front of it. These cases baffled me, for I could not ascertain the condition in the ileo-cæcal region because the last coils of the ileum lay in contiguity with the cæcum and their shadow could not be distinguished from that of the cæcum. Manual pressure could not be effectively brought to bear upon them; moreover, the surgeon could not demonstrate the condition at operation, for he could not examine the ileo-cæcal region without extracting it from the pelvis. It then occurred to me that by placing the patient in the oblique positions on the couch (thorax and abdomen tilted to about 45°), as had long been my practice for examining the hepatic and splenic flexures, I might get the desired results. My plan succeeded. I derived information at once striking and undeniable. In each case the main features are quite constant, though details vary. The terminal coil of the ileum is found to be dilated and tortuous; it exhibits abnormally powerful peristalsis. There is spasm at the ileo-cæcal entrance varying in degree, but in severe cases it amounts to a tight obstructive spasm. An irregularly constricted portion within an inch of the ileo-cæcal entrance is nearly always found. In front of the peristaltic wave the coil bulges. As the wave approaches the constricted portion of the terminal coil of the ileum the bismuth is seen to flow back through the coil instead of completing its journey into the cæcum. This is due to torsion of the coil near its termination—a condition brought about by the backward rotation of the cæcum in the pelvis. In the most severe cases the cæcum actually points upward behind the ascending colon, a position which imposes on the terminal ileum an axial rotation through 180°. Mr. Tyrrell Gray operated recently in one of those cases where the cæcum lay deep in the pelvis. As he drew the cæcum up into view it was seen to curl up like a periwinkle when it is extracted from its shell. It was a remarkable illustration of how ileal torsion is produced and established.

Ileal torsion causes ileal stasis, for (1) the torsion causes a mechanical narrowing of the lumen of the bowel; and (2) it interferes with the vascular and nervous supply of the coil to such an extent that partial paralysis of the constricted part of the coil is produced; (3) it induces chronic irritation in the coil and sets up reflex spasm at the ileo-cæcal entrance.

The position of the appendix is important. In most cases its proximal portion is directed upwards and backwards from the inner and hind wall of the cæcum. In this position the appendix is almost certain to cause a hindrance to the passage of the contents of the ileum into the cæcum. In a smaller number of cases the appendix is directed downwards and gives rise to no inconvenience.

The radiological study of the prolapsed cæcum throws a great deal of light upon chronic intestinal stasis.

Colitis and Diverticulitis.

The inevitable result of stasis in the large intestine is catarrh of the mucous membrane—usually called colitis. Colitis is nature's attempt to evacuate the stagnant fæcal matter by secreting mucus in the bowel. Her success is very limited. The latter portions of the large intestine become reduced in calibre by spasm, while the cæcum and the ascending colon become dilated, and remain full of stagnant matter. In the hepatic flexure region bismuth material is suspended in mucus; in the rest of the large intestine small portions of

material are propelled through the thread-like calibre of the contracted bowel as far as the rectum, where they accumulate until voided. The spasm set up by catarrh of the mucous membrane becomes so persistent at last that it rarely if ever, relaxes. A thin streak of bismuth is seen day after day in the descending, iliac and pelvic colon, while the bulk of the bismuth remains behind in the dilated cæcum and ascending colon. When the cæcum has dropped into the deepest part of the pelvis it may remain full of bismuth for days in spite of repeated attempts to evacuate it by aperients and enemata. Persistent spasm of the descending and iliac colon leads to thickening of the walls of the bowel, causing the iliac colon to be felt as a firm cord in the left iliac fossa.

What is the final outcome of colitis? If unrelieved, it may lead to new growth. The new growth may arise in the cæcum, where the long retention of stagnant fæces is a potent irritant, or at the hepatic or splenic flexure or in the iliac or pelvic colon, where the spasm produces the greatest pressure. In the iliac colon another result may follow. If this portion of the bowel is fixed to the left iliac fossa (Lane's last kink), and if the bowel wall is infiltrated with fat, as occurs in stout elderly subjects, the bowel wall may become so sodden that it yields to the pressure, and the mucous membrane is forced through the interstices of the weakened muscle of the bowel wall, and gives rise to the condition now known as diverticulitis. An infiltration of leucocytes follows the protrusion of the sacs, and a tumour appears in the left iliac fossa. The tumour formed by diverticulitis is usually mistaken, clinically, for a malignant growth, and, indeed, malignant disease not infrequently supervenes. Under suitable treatment the tumour may disappear. The iliac colon is the site where diverticulitis most frequently occurs, but it may occur on the proximal side of any obstructed or abnormally tortuous portion of the large intestine, and it has been found at the splenic and hepatic flexures and in the ascending colon. I have seen diverticulitis in all these situations. Diverticulitis is, in fact, a special sequel of colitis, which is due to chronic intestinal stasis. The recent discussion on this subject at the Royal Society of Medicine has awakened wide interest in this condition. Although the first acknowledged description dates from 1907, the discussion brought to light the remarkable fact that it had been described, illustrated, and explained by Sir Arbuthnot Lane as early as 1886 in a paper published in the Guy's Hospital Reports. Extracts from these reports were reprinted in THE LANCET of Jan. 24th, 1920, p. 220.

The Undescended Cæcum.

The congenital undescended cæcum is another cause of ileal stasis. It may seem irrational to include, as a cause of stasis, a somewhat rare condition, but as I have seen 14 cases in my own consulting room in the last four years, these cases probably exist in greater number than is supposed. The condition cannot be recognised clinically, and it is often overlooked by radiologists. In the early weeks of fœtal life the cæcum lies in the epigastrium in front of the lower part of the duodenum. As the bowel grows in length the cæcum moves to the right till it reaches the liver; thence it follows the lower border of the liver down to the right flank, where it lies in front of the right kidney, separated from it by some coils of the small intestine. Before reaching its final position in the right iliac fossa the coils of the small intestine fall, allowing the cæcum to come in contact with the posterior abdominal wall. Here it acquires adhesions which keep it in position. Occasionally it happens that the small intestine falls away from behind the cæcum prematurely, allowing the cæcum to make contact with the posterior abdominal wall at a level higher than the normal. The cæcum at once becomes adherent in its abnormal position. With the continued growth in length of the large intestine the ascending colon droops below the cæcum, and the cæcum becomes inverted. The terminal coil of the ileum is the one portion which cannot escape when the rest of the small bowel falls from behind the cæcum, for it is attached to the cæcum at the abnormally high ileo-cæcal entrance. This coil is imprisoned and caught in the bands which bind the cæcum to the posterior parietes. In well-marked cases of the abnormality the imprisoned terminal ileum is obstructed, and becomes an important source of ileal stasis. On operating on a case of this kind recently, Mr. Tyrrell Gray found the last few inches of the ileum running up behind the inverted cæcum, and becoming retro-peritoneal. The free portion of the ileum below the obstructed terminal portion was greatly dilated and hypertrophied.

The Results of Ileal Stasis.

We have now considered most of the causes of ileal stasis. They may be grouped as follows: (1) Lane's ileal kink; (2) the controlling appendix; (3) the dropped cæcum with ileal torsion; (4) the catarrhal cæcum (colitis) with spasm at the ileo-cæcal entrance; (5) the congenital inverted cæcum with the terminal ileum retro-peritoneal.

Although ileal stasis can be produced at least in these five different ways, the results are the same in all cases. These are: (1) Overloading of the lower coils of the ileum, and consequent dropping of these coils into the pelvis. (2) Continued traction on the mesentery of the small intestine, causing it to fall, little by little, from its line of attachment along the posterior parietal wall till the dropping includes all parts of the small intestine, and a kink is produced at the duodeno-jejunal junction. (3) This kink leads to distension of the duodenum.

In addition to these mechanical results of ileal stasis, there are other consequences of the gravest importance. The chief of these is microbic invasion. The stagnant contents which lie in the lower coils of the small intestine convert these coils into breeding-places for virulent micro-organisms. This microbic invasion produces its effects in two ways: (1) A general toxæmia which renders every tissue of the body unhealthy and vulnerable to the attacks of invading microbes. (2) Locally, in the digestive tract, where the microbes invade the duodenum, and even the stomach.

Invasion by Pathogenic Micro-organisms.

The invasion of the distended duodenum by pathogenic micro-organisms leads to congestion of the mucous membrane, and later to ulceration. The microbes may extend into the common bile-duct and give rise to cholecystitis and pancreatitis. Duodenal distension leads in all cases to pyloric spasm.

The invasion of the microbes determines the onset of gastric ulcer at the pylorus or in some other part of the stomach. Here, again, cancer may bring the unhappy history to its close. In the short time available I cannot enter fully into this aspect, but it is familiar to you all, and has been described in recent books and papers dealing with the subject.[3] A well-known physician recently wrote in the journal of his hospital: "Cancer of the stomach comes generally 'out of the blue,' with no preceding history of gastric trouble." I find myself in direct disagreement with this view. I can scarcely recall or find notes of a single case which supports it. The patient may have grown so accustomed to his digestive disorder as to be unaware of it, or at any rate to make no complaint of it. The radiological investigation, however, reveals incontrovertible evidence of long-standing disorder.

Here, for instance, is the case of a lady whose gastric cancer came to her "out of the blue." On careful questioning, it transpired that she had always been inclined to biliousness and constipation. I found an enormously elongated pelvic colon, rising into the right hypochondrium, in contact with the hepatic flexure. Moreover, her cæcum was firmly impacted in the pelvis. On making a digital examination of the rectum the cæcum was encountered full of hard nodular contents, firmly pressed into the rectum. It is certain that she had for years been endeavouring to force her cæcum out through the wall of the rectum whenever she went to stool. The highest point of the alimentary tract which is affected by the change of events which follows upon ileal stasis is the cardiac orifice of the œsophagus. Persistent pyloric spasm leads to enlargement of the stomach, and then there occurs an abnormal traction upon the cardiac orifice. In certain cases this leads to persistent spasm of the cardiac orifice, causing obstruction and dilatation of the œsophagus. This condition of cardiospasm may persist for many years and lead to enormous dilatation of the œsophagus. In all cases of cardiospasm the stomach is found to be enlarged and dropped, in marked contrast to the small contracted stomach usually associated with œsophageal obstruction due to organic stenosis.

General Results of Toxæmia.

As already stated, the toxic absorption which occurs in stasis exerts its deleterious effects upon every tissue. Thus we find atheroma of the aorta at an early age in the subjects of severe stasis. Most glands suffer changes. The breasts become subject to chronic mastitis at an early stage of stasis; at a more advanced stage cystic disease of the breasts occurs, and may end in cancer. The thyroid gland suffers in various ways, the most usual change being atrophy. Exophthalmic goitre occurs in some subjects of stasis; cysts and adenomata of the thyroid are well-known sequels of stasis, and here again cancer may be the last stage. Chronic pancreatitis is one of the most constant changes in stasis. It may lead to cancer, or to glycosuria, ending in true diabetes mellitus. The joints become vulnerable to the tubercle bacillus, and to the micro-organisms which produce rheumatoid arthritis and Still's disease. In regard to tubercle, Sir Arbuthnot Lane states his conviction that tubercle cannot gain a hold on the lungs or any part of the human body except in the presence of stasis. The observations of Sir James Mackenzie go far to confirm this view. His opinion is stated in the clearest possible way in his latest book, "The Future of Medicine." Dr. A. White Robertson[4] has come to the same conclusion as the result of his studies on the effects of toxins, and has stated very definitely his conclusions that tuberculosis, rheumatism, and many other chronic diseases are the effect of the toxins which pervade the tissues as a result of absorption from the intestine in chronic intestinal stasis. Dr. White Robertson is now achieving the most far-reaching results by the treatment of tuberculosis with detoxicated coli and other vaccines.

The Treatment of Chronic Intestinal Stasis.

This can only be considered in outline. It falls under four groups: (1) Surgical, (2) mechanical, (3) medical, (4) bacteriological. If the radiological observations disclose a mechanical obstruction, such as constricting bands or a controlling appendix, surgical interference is the obvious remedy. A simple operation upon the appendix or the division of bands may bring about the desired result. Another group of cases in which operative procedure is necessary comprises the end results of stasis, such as a cicatrised ulcer in the stomach or duodenum or an impacted gall-stone. The immediate results of these operations for the relief of obstruction are so gratifying that the surgeon is apt to overlook the fact that he has not dealt with the primary cause—namely, the stasis. The medical treatment of stasis requires skill and perseverance. Treatment consists in the administration of liquid paraffin and other aperients, diet, regime, and other hygienic measures. The mechanical treatment includes massage and abdominal supports. The simplest efficient support is the "Curtis" belt, designed by Sir Arbuthnot Lane. The bacteriological treatment consists of the injection of vaccines prepared from the pathogenic micro-organisms found in the fæces, the urine, the sputum, the throat, or the gums. In the most advanced cases, when the large intestine has become diseased beyond repair by the ravages of microbes responsible for the production of colitis, all these measures may fail to give more than a slight degree of relief. In these cases the best prospect is undoubtedly found in the removal of the large intestine. It is hardly necessary to say that this is never undertaken unless all other means have failed, or are foredoomed to failure. The results of a successful colectomy are so brilliant as to seem almost miraculous, and prove beyond doubt that the diseased intestine has been the source of all the trouble.

DEATH OF MR. G. B. ELLIOTT.—George Blacker Elliott, Major R.A.M.C., who died at Brixham, Devon, on March 22nd, in his 56th year, was the youngest son of the late Mr. W. Armstrong Elliott, F.R.C.S. Irel., of Dublin. He had been in practice for many years at Brixham, where he was on the honorary medical staff of the cottage hospital, medical officer of health for the urban district, Admiralty surgeon and agent.

THE PEOPLE'S LEAGUE OF HEALTH.—The League is urging borough councils and Poor-law guardians wherever possible to take over the buildings of discontinued military hospitals and to open them as paying maternity hospitals at a fee of about a guinea. Allowing for a minimum stay in hospital of three weeks after confinement and the increased maternity benefit of £2, only an additional £1 3s. or so would remain to be found by the prospective parents. The welfare committee of the Hampstead Borough Council has reported favourably on this suggestion.

THE ELECTRICAL STIMULATION OF NERVES AT OPERATION

By NOEL H M BURKE, M R C S, L R C P Lond
LATELY MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENT HORTON WAR HOSPITAL EPSOM

DURING the years 1915 to 1917 a number of observations on this subject were made at the Horton and Manor War Hospitals at Epsom, and the results obtained, with such lessons as appear to be deducible from the experience gained in a series of some 80 cases, may be of interest

The first matter to be decided upon is the choice of apparatus and of method and the following fundamental considerations have led to the adoption of a certain routine

1 Since a nerve is a small and delicate structure *which at the greatest is little thicker than a pencil, and* since access is through the comparatively small opening of an operation wound, the electrode must be compact, easily held and manipulated even in the depths of a small wound, and capable of thorough sterilisation

2 The surgeon dislikes interruption or interference with the course of his manipulations and the anæsthetist sometimes objects to prolongation of anæsthesia, so that any electrical examination should be rapid and simple

3 With the *direct* current it is easy to burn any tissues which are in contact with the electrodes, and though it is possible to lessen this danger by suitable precautions, it is safer to use the *induction coil* current only The results appear to be similar and equally valuable

After the first few attempts, with varying devices, I have come to regard the following apparatus as meeting all the requirements of practical importance —

1 A Lewis Jones sledge coil, which is handy and portable and can be put on a chair or stool well out of the way of the operator and his assistants

2 Two long cables are attached to the terminals of this machine, and their peripheral ends, for about 3½ or 4 feet, are cased in good rubber tubing made continuous with the insulation of the bi polar electrode The rubber ends can be boiled in the steriliser and thereafter form part of the sterile apparatus for handling by the surgeon and others who are "clean," while the central end above the rubber tubing is unclean, and can be freely handled by the electrologist, neurologist, or such assistant as may be appointed to control the coil

3 The electrode I have found most useful is a small telephone plug, with the two pins bent towards each other Around its junction with the cables rubber tape is tightly wound and the joints sealed with pure rubber solution

Object of the Examination

The functions of the nerve which it is possible to investigate are those of excitability and conductivity. When stimulation of the nerve above the lesion leads to muscular contraction this is mainly evidence of physiological continuity of the nerve through the area of injury—that is to say, a demonstration of conductivity The excitability of the central end is not likely to suffer to a great extent Contraction obtained by stimulating below the lesion is mainly evidence of the excitability of the peripheral portion of the nerve trunk It is also a proof of conductivity in this lower part of the nerve, but the extent to which this must be considered is discussed below It is necessary, therefore, to examine the result of stimulation of the nerve trunk above and below the level of the lesion, both before and after dissection of the nerve from scar tissue and adhesions This is not really difficult from the surgeon's point of view, because the majority are cases of compression in scar tissue rather than of complete division, and in most of these the result of the wound and the subsequent scarring has led to deformity from normal relationships Most surgeons therefore first look for the nerve above and below the wound level, so as to find it easily in its proper position, and then trace it down and up into the area of lesion This rule applies to nearly all operations for nerve injury, and, indeed, the few operators who try to find the nerve directly in the midst of the area of injury soon find themselves in difficulties, and may do damage This rule has lately been emphasised by Sir Robert Jones

Method

The first two or three observations were made with a pin electrode on the nerve, and a large indifferent electrode on some distant part of the body. This, however, seemed to be calculated to increase the liability of the stimulation to spread to other structures than the nerve under observation, and to tend to inaccuracy, it also led to the inconvenience of wires diverging to opposite ends of the operating table, instead of both going close together to the site of operation only. For these reasons the small bi polar electrode was adopted for general use

Strength of stimulus —The coil is adjusted to yield the current which experience has shown to be sufficient to produce an obvious contraction in an average normal case, This has been regarded as the standard strength of stimulation, and provides a measure for the rough comparison of results which alone is possible under the conditions already described *Minute measurement* is not practicable The general idea is to use the constant strength and to note the results obtained under varying conditions

Method of stimulation —The nerve trunk having been isolated in its undamaged portion above the lesion, is gently lifted on a hook so as to be free of surrounding structures The electrode is then applied, so *that the two pin terminals* lie evenly and lightly on the trunk the current is turned on, and the result noted The observation is rapidly repeated with the electrode applied *to different aspects of* the nerve surface in order to pick out separate muscles with greater accuracy The same observations are made for the portion of the nerve below the injury *Dissection* is then finished, and if the nerve is found to be in anatomical continuity the tests are repeated on the liberated nerve

Observation —It is necessary to have good exposure of the hand, foot or other part in which movement is to be sought for This part need not be "clean unless the surgeon himself is making the observation The examination of the result of stimulation must be done with scrupulous care by someone accustomed to the business, so that a minute muscular contraction is not missed, nor the nature of a movement misinterpreted For instance, if the median nerve has been stimulated and the thumb moves, it is necessary to be certain whether the movement is of median type and *signifies a fairly sound* nerve or of ulnar type due to spreading of the current and signifying at least much depression of the physiological activity of the median

Discussion of Observations

These examinations were made at first rather with a view to gaining information *about the conditions* present in nerve injuries than as a means of guiding the surgeon's decision From the results obtained certain ideas quickly suggested themselves and will be mentioned below It is not easy to collect the information into a simple form that is easily read, but an attempt has been made in the bring the unhappy history to its close. In the short time available I cannot enter fully into this aspect, but it is familiar to you all, and has been described in recent books and papers dealing with the subject.[3] A well-known physician recently wrote in the journal of his hospital: "Cancer of the stomach comes generally 'out of the blue,' with no preceding history of gastric trouble." I find myself in direct disagreement with this view. I can scarcely recall or find notes of a single case which supports it. The patient may have grown so accustomed to his digestive disorder as to be unaware of it, or at any rate to make no complaint of it. The radiological investigation, however, reveals incontrovertible evidence of long-standing disorder.

Here, for instance, is the case of a lady whose gastric cancer came to her "out of the blue." On careful questioning, it transpired that she had always been inclined to biliousness and constipation. I found an enormously elongated pelvic colon, rising into the right hypochondrium, in contact with the hepatic flexure. Moreover, her cæcum was firmly impacted in the pelvis. On making a digital examination of the rectum the cæcum was encountered full of hard nodular contents, firmly pressed into the rectum. It is certain that she had for years been endeavouring to force her cæcum out through the wall of the rectum whenever she went to stool. The highest point of the alimentary tract which is affected by the change of events which follows upon ileal stasis is the cardiac orifice of the œsophagus. Persistent pyloric spasm leads to enlargement of the stomach, and then there occurs an abnormal traction upon the cardiac orifice. In certain cases this leads to persistent spasm of the cardiac orifice, causing obstruction and dilatation of the œsophagus. This condition of cardiospasm may persist for many years and lead to enormous dilatation of the œsophagus. In all cases of cardiospasm the stomach is found to be enlarged and dropped, in marked contrast to the small contracted stomach usually associated with œsophageal obstruction due to organic stenosis.

General Results of Toxæmia.

As already stated, the toxic absorption which occurs in stasis exerts its deleterious effects upon every tissue. Thus we find atheroma of the aorta at an early age in the subjects of severe stasis. Most glands suffer changes. The breasts become subject to chronic mastitis at an early stage of stasis; at a more advanced stage cystic disease of the breasts occurs, and may end in cancer. The thyroid gland suffers in various ways, the most usual change being atrophy. Exophthalmic goitre occurs in some subjects of stasis; cysts and adenomata of the thyroid are well-known sequels of stasis, and here again cancer may be the last stage. Chronic pancreatitis is one of the most constant changes in stasis. It may lead to cancer, or to glycosuria, ending in true diabetes mellitus. The joints become vulnerable to the tubercle bacillus, and to the micro-organisms which produce rheumatoid arthritis and Still's disease. In regard to tubercle, Sir Arbuthnot Lane states his conviction that tubercle cannot gain a hold on the lungs or any part of the human body except in the presence of stasis. The observations of Sir James Mackenzie go far to confirm this view. His opinion is stated in the clearest possible way in his latest book, "The Future of Medicine." Dr. A. White Robertson[4] has come to the same conclusion as the result of his studies on the effects of toxins, and has stated very definitely his conclusions that tuberculosis, rheumatism, and many other chronic diseases are the effect of the toxins which pervade the tissues as a result of absorption from the intestine in chronic intestinal stasis. Dr. White Robertson is now achieving the most far-reaching results by the treatment of tuberculosis with detoxicated coli and other vaccines.

The Treatment of Chronic Intestinal Stasis.

This can only be considered in outline. It falls under four groups: (1) Surgical, (2) mechanical, (3) medical, (4) bacteriological. If the radiological observations disclose a mechanical obstruction, such as constricting bands or a controlling appendix, surgical interference is the obvious remedy. A simple operation upon the appendix or the division of bands may bring about the desired result. Another group of cases in which operative procedure is necessary comprises the end results of stasis, such as a cicatrised ulcer in the stomach or duodenum or an impacted gall-stone. The immediate results of these operations for the relief of obstruction are so gratifying that the surgeon is apt to overlook the fact that he has not dealt with the primary cause—namely, the stasis. The medical treatment of stasis requires skill and perseverance. Treatment consists in the administration of liquid paraffin and other aperients, diet, regime, and other hygienic measures. The mechanical treatment includes massage and abdominal supports. The simplest efficient support is the "Curtis" belt, designed by Sir Arbuthnot Lane. The bacteriological treatment consists of the injection of vaccines prepared from the pathogenic micro-organisms found in the fæces, the urine, the sputum, the throat, or the gums. In the most advanced cases, when the large intestine has become diseased beyond repair by the ravages of microbes responsible for the production of colitis, all these measures may fail to give more than a slight degree of relief. In these cases the best prospect is undoubtedly found in the removal of the large intestine. It is hardly necessary to say that this is never undertaken unless all other means have failed, or are foredoomed to failure. The results of a successful colectomy are so brilliant as to seem almost miraculous, and prove beyond doubt that the diseased intestine has been the source of all the trouble.

DEATH OF MR. G. B. ELLIOTT.—George Blacker Elliott, Major R.A.M.C., who died at Brixham, Devon, on March 22nd, in his 56th year, was the youngest son of the late Mr. W. Armstrong Elliott, F.R.C.S. Irel., of Dublin. He had been in practice for many years at Brixham, where he was on the honorary medical staff of the cottage hospital, medical officer of health for the urban district, Admiralty surgeon and agent.

THE PEOPLE'S LEAGUE OF HEALTH.—The League is urging borough councils and Poor-law guardians wherever possible to take over the buildings of discontinued military hospitals and to open them as paying maternity hospitals at a fee of about a guinea. Allowing for a minimum stay in hospital of three weeks after confinement and the increased maternity benefit of £2, only an additional £1 3*s.* or so would remain to be found by the prospective parents. The welfare committee of the Hampstead Borough Council has reported favourably on this suggestion.

THE ELECTRICAL STIMULATION OF NERVES AT OPERATION.

By NOEL H. M. BURKE, M.R.C.S., L.R.C.P. LOND.,
LATELY MEDICAL OFFICER IN CHARGE OF THE ELECTRICAL DEPARTMENT, HORTON WAR HOSPITAL, EPSOM

DURING the years 1915 to 1917 a number of observations on this subject were made at the Horton and Manor War Hospitals at Epsom, and the results obtained, with such lessons as appear to be deducible from the experience gained in a series of some 80 cases, may be of interest.

The first matter to be decided upon is the choice of apparatus and of method, and the following fundamental considerations have led to the adoption of a certain routine.

1. Since a nerve is a small and delicate structure, which at the greatest is little thicker than a pencil, and since access is through the comparatively small opening of an operation wound, the electrode must be compact, easily held and manipulated even in the depths of a small wound, and capable of thorough sterilisation.
2. The surgeon dislikes interruption or interference with the course of his manipulations and the anæsthetist sometimes objects to prolongation of anæsthesia, so that any electrical examination should be rapid and simple.
3. With the *direct* current it is easy to burn any tissues which are in contact with the electrodes, and though it is possible to lessen this danger by suitable precautions, it is safer to use the *induction coil* current only. The results appear to be similar and equally valuable.

After the first few attempts, with varying devices, I have come to regard the following apparatus as meeting all the requirements of practical importance.—

1. A Lewis Jones sledge coil, which is handy and portable and can be put on a chair or stool well out of the way of the operator and his assistants.
2. Two long cables are attached to the terminals of this machine, and their peripheral ends, for about 3½ or 4 feet, are cased in good rubber tubing made continuous with the insulation of the bi-polar electrode. The rubber ends can be boiled in the steriliser and thereafter form part of the sterile apparatus for handling by the surgeon and others who are "clean," while the central end above the rubber tubing is unclean, and can be freely handled by the electrologist, neurologist, or such assistant as may be appointed to control the coil.
3. The electrode I have found most useful is a small telephone plug, with the two pins bent towards each other. Around its junction with the cables rubber tape is tightly wound and the joints sealed with pure rubber solution.

Object of the Examination.

The functions of the nerve which it is possible to investigate are those of excitability and conductivity. When stimulation of the nerve above the lesion leads to muscular contraction this is mainly evidence of physiological continuity of the nerve through the area of injury—that is to say, a demonstration of conductivity. The excitability of the central end is not likely to suffer to a great extent. Contraction obtained by stimulating below the lesion is mainly evidence of the excitability of the peripheral portion of the nerve trunk. It is also a proof of conductivity in this lower part of the nerve, but the extent to which this must be considered is discussed below. It is necessary, therefore, to examine the result of stimulation of the nerve trunk above and below the level of the lesion, both before and after dissection of the nerve from scar tissue and adhesions. This is not really difficult from the surgeon's point of view, because the majority are cases of compression in scar tissue rather than of complete division, and in most of these the result of the wound and the subsequent scarring has led to deformity from normal relationships. Most surgeons therefore first look for the nerve above and below the wound level, so as to find it easily in its proper position, and then trace it down and up into the area of lesion. This rule applies to nearly all operations for nerve injury, and, indeed, the few operators who try to find the nerve directly in the midst of the area of injury soon find themselves in difficulties, and may do damage. This rule has lately been emphasised by Sir Robert Jones.

Method.

The first two or three observations were made with a pin electrode on the nerve, and a large indifferent electrode on some distant part of the body. This, however, seemed to be calculated to increase the liability of the stimulation to spread to other structures than the nerve under observation, and to tend to inaccuracy; it also led to the inconvenience of wires diverging to opposite ends of the operating table, instead of both going close together to the site of operation only. For these reasons the small bi-polar electrode was adopted for general use.

Strength of stimulus.—The coil is adjusted to yield the current which experience has shown to be sufficient to produce an obvious contraction in an average normal case. This has been regarded as the standard strength of stimulation, and provides a measure for the rough comparison of results which alone is possible under the conditions already described. Minute measurement is not practicable. The general idea is to use the constant strength and to note the results obtained under varying conditions.

Method of stimulation.—The nerve trunk, having been isolated in its undamaged portion above the lesion, is gently lifted on a hook so as to be free of surrounding structures. The electrode is then applied, so that the two pin terminals lie evenly and lightly on the trunk, the current is turned on, and the result noted. The observation is rapidly repeated, with the electrode applied to different aspects of the nerve surface, in order to pick out separate muscles with greater accuracy. The same observations are made for the portion of the nerve below the injury. Dissection is then finished, and if the nerve is found to be in anatomical continuity the tests are repeated on the liberated nerve.

Observation.—It is necessary to have good exposure of the hand, foot, or other part in which movement is to be sought for. This part need not be "clean," unless the surgeon himself is making the observation. The examination of the result of stimulation must be done with scrupulous care by someone accustomed to the business, so that a minute muscular contraction is not missed, nor the nature of a movement misinterpreted. For instance, if the median nerve has been stimulated and the thumb moves, it is necessary to be certain whether the movement is of median type and signifies a fairly sound nerve, or of ulnar type due to spreading of the current, and signifying at least much depression of the physiological activity of the median.

Discussion of Observations.

These examinations were made at first rather with a view to gaining information about the conditions present in nerve injuries than as a means of guiding the surgeon's decision. From the results obtained certain ideas quickly suggested themselves, and will be mentioned below. It is not easy to collect the information into a simple form that is easily read, but an attempt has been made in the accompanying table to show the evidence on the main points, and from this evidence certain facts emerge.

TABLE OF RESULTS. CONDUCTIVITY AND EXCITABILITY BEFORE AND AFTER FREEING THE NERVE.

(a) *Complete Division of Nerve* (25 cases).

Conductivity.		Excitability.	
Before.	After.	Before.	After.
19 absent. 6 no test.	— —	19 absent. 6 no test.	— —
(b) *Nearly Complete Division of Nerve* (13 cases).			
3 present.	1 present. 2 diminished.	1 absent. 1 much dim. 1 ? absent.	1 absent. 1 much dim. 1 diminished.
1 ?	1 no test.	1 no test.	1 very weak.
4 absent.	3 absent. 1 no test.	3 absent. 1 no test.	2 absent. 1 no test. 1 weak.
5 no test.	5 no test.	2 ? 1 absent. 2 no test.	2 ? 1 absent. 1 present. 1 no test.
(c) *Slight Division of Nerve* (2 cases).			
1 present. 1 present.	1 present. 1 diminished.	1 weak. 1 present.	1 weak. 1 improved.
(d) *Scar Tissue* (42 cases).			
19 present.*	5 improved. 8 unchanged. 1 absent. 5 no test.	20 present.	8 improved. 5 unchanged. 7 no test.
1 ?	1 absent.	1 ? present.	1 present.
6 absent.†	2 present. 3 absent. 1 no test.	10 absent.	4 present. 6 absent.
16 no test.	16 no test.	11 no test.	5 present. 5 absent. 1 no test.

* One had causalgia and no visible or palpable scar. One had two operations on the same nerve, at different levels.

† One had causalgia and much scar. One had two operations on the same nerve on contiguous portions, the second time not tested.

1. No response was obtained on stimulation of the nerve in any case of complete division.

2. Cases of severe injury amounting to obvious destruction of more than half the cross-section of a nerve showed some response to stimulation in a fair number of instances, and the response was in general diminished after dissection was complete. Sometimes this would suggest that the dissection had divided a few surviving fibres that were much involved in scar tissue but still physiologically active.

3. Among these and other fairly severe cases one or two were noticed which seemed to show fatigue or diminished activity, either as a result of much manipulation or of much stimulation. These were not numerous enough to dogmatise upon, but suggest a line for further investigation.

4. Conductivity when present may be of normal or diminished quality.

5. A muscular contraction in response to stimulation of the central portion of the nerve is proof not only that conductivity is present through the area of injury, but also, of necessity, that it is present in the whole peripheral portion of the nerve. Nevertheless, it is possible to have in this lower portion a diminished or even absent excitability to such stimuli as are applied in this method, although the nerve can conduct an impulse from above.

6. In the two cases where slight division was the predominant feature each gave response, one showing improvement of excitability but diminished conductivity after dissection.

7. The scar cases were, of course, a mixed set, including those which showed no macroscopic evidence of section of fibres and a greater or less degree of fibrous formation about the nerve trunk. The greater number showed a conductivity more or less preserved (19 out of 26 examined), while 20 out of 31 showed excitability. Both qualities were in general improved after neurolysis; only 1 case showed a diminution, and this was of conductivity.

8. It is only with a fairly sound nerve that anything like a general contraction of the whole muscle group is seen. Mostly one gets only a contraction of one or two larger muscles. This is a drawback in estimating the condition of the nerve from the results seen in such a state as partial division, as the contraction produced does not necessarily mean that no fibres have been divided.

9. It is easy when stimulating a seriously injured nerve to get a contraction of muscles supplied by a neighbouring healthy nerve, somewhat as is seen in ordinary clinical muscle testing. This spreading of stimulation is lessened if the nerve is held up on a hook away from other tissues, so that the maximum intensity of the current is applied to the nerve, and can only get to neighbouring tissues through its long axis.

10. It has been very instructive to examine, treat, and report on cases before operation, and then to go and see what condition was actually found on the table. It has also been a help, in deciding on the course of treatment after operation, to know exactly what has been done.

11. For these reasons, and because he has the responsibility of the greater part of the period of treatment in these cases, the electrotherapist should collaborate closely with the surgeon and should attend the operations on his patients whenever possible.

12. One way in which the experience of this series has been of interest is in the light it has thrown on the accuracy of diagnostic methods and their interpretation. The reports from the electrical department endeavoured to indicate the probable degree of injury (complete division, much scar tissue, division of a few fibres only, &c.) and comparison of the opinions given in reports before operation and the actual findings shows the following results: Diagnosis correct, 41 cases; approximately correct, 18; about half right, 11; about a quarter right, 1; quite wrong, 1. The error was due to optimistic interpretation in 13 cases and five times to pessimism.

Conclusions and Lessons.

(1) Every case should be tested, as a fair number of decisions are made easier by the information obtained and an unnecessary section of an undivided nerve may be thereby avoided. This was strongly brought home in a recent case, not included in the series, where the median nerve had been exposed high in the axilla. The surgeon, his assistant, and I all felt the mass of scar tissue into which the nerve was traced, and all thought we detected a definite end to the nerve course. On stimulation, however, contraction was obtained. Without this demonstration it is quite probable that the nerve would have been divided at its apparent cut end in order to make further dissection simpler.

(2) Conductivity is conclusive evidence of physiological continuity of nerve fibres, as also is excitability below the lesion.

(3) Improvement in conductivity or in peripheral excitability following immediately after neurolysis is suggestive of only slight compression and possibly chemical nerve-block.

(4) Absence of conductivity and of excitability, even after neurolysis, is not conclusive evidence of division, but is probably an indication of fairly severe nerve disturbance.

I have to express my thanks for the ready kindness of the surgeons who have allowed me to make my investigations while they operated: Major H. Makin and Captains G. Owen and J. McGee, of the Australian Imperial Force; Majors A. Paling, M. G. Riches, and A. F. Stabb, and Captain Lawson Whale, of the R.A.M.C.; and Mr. W. S. Fenwick and Mr. R. Warren, who were consulting surgeons to Horton War Hospital. I have also to thank Lieutenant-Colonels J. R. Lord and S. Elgee, R.A.M.C. officers commanding the two hospitals, for kind permission to publish this paper.

FATAL ANAPHYLAXIS

FOLLOWING THE PROPHYLACTIC ADMINISTRATION OF ANTITETANIC SERUM.

BY FRASER B. GURD, M.D. McGILL,
AND
E. EMRYS-ROBERTS, M.D. LIVERP.

THAT the parenteral introduction of foreign protein in the form of antisera is not infrequently accompanied by more or less important constitutional and local manifestations of irritation or intoxication is generally appreciated. Fortunately, such symptoms consist, as a rule, simply in the development, a few (2 to 14) days after the injection, of urticarial and erythematous eruptions, and joint or muscle pains, accompanied sometimes by a certain degree of pyrexia. The patient is often very unhappy, but otherwise such examples of serum sickness are not of sufficient importance to contra-indicate the employment of sera for either prophylactic or therapeutic purposes.

From time to time, during the past 15 years, cases of severe and fatal reaction following the administration of horse serum have been recorded. The great majority of these cases have occurred among patients receiving the serum in the treatment of their infections. In the prophylactic injection of antitoxin-containing sera—e.g., antidiphtheritic and antitetanic sera—the amount of protein introduced is relatively very small and the material is commonly injected into the subcutaneous tissues. In consequence very few serious accidents have occurred.

Report of Case.

The case reported in this paper proves the possibility of a fatal reaction to the administration of horse serum in small doses. This case is reported, not as an objection to the routine injection of all wounded with antitetanic serum, but rather in order that a rare clinical accident may be placed upon record.

L./Sgt. E. was admitted to a casualty clearing station on Sept. 1st, 1916, at 10.15 A.M. A few hours previously he had received several small bomb wounds of both hands, the right thigh, and left calf. All wounds upon examination were found to be unimportant. The patient was in good general condition; he was a well-built man about 30 years of age. Pulse and temperature were normal.

As the patient had not received his antitetanic serum prior to admission, this was administered at 11.15 A.M. 750 units (U.S.A.) contained in 5 c.cm. of serum were injected subcutaneously over the right pectoralis major muscle. (There is the possibility that part of the serum was injected into the muscle.) The patient remained well until 1.30 P.M., two and a quarter hours after the serum inoculation, at which hour he commenced to vomit, and had a bloody diarrhœa. This gastro-intestinal disturbance was accompanied by a moderate degree of collapse. Between 1.30 and 5 P.M. he vomited eight times, and had six bowel movements. All bowel evacuations contained blood. The stools were watery, and contained small particles of fæces, and a moderate amount of small blood clot. The sister in charge of the case noted no blood in the vomitus.

Examination at 5 P.M. resulted in the following notes: "Pulse 104, temp. 102·8° F. Patient complains of moderate headache and thirst. There is slight generalised abdominal tenderness, no rigidity. The chest is negative, no complaint of respiratory distress, despite the fact that he is cyanosed and restless. The skin is 'goose-fleshed,' and covered with a mild erythema." From 5 P.M. to 11 P.M. the patient remained in this state of moderately severe collapse. He received water by mouth, otherwise no treatment was instituted, as his condition was not alarming.

At 11 P.M., after a slight vomiting attack, the collapsed state became very severe. He became pulseless at the radials, heart beat rose to 160–170. Extreme cyanosis supervened, and restlessness increased. During the night stimulation was pressed to the utmost. Pituitary extract, 1 c.cm. to the dose, was given every three hours. Strychnine, 1/30 gr., was given at 11 P.M., and continued in doses of 1/40 gr. every three hours. He received 3 pints of saline subcutaneously during the night, and oxygen almost continuously up to the time of death. Except for the fact that he became quieter and more comfortable while receiving oxygen, there was no response to stimulation.

At 6 A.M. on Sept. 2nd the following notes were made: "Pulse is absent at the wrist, heart-rate 180 and feeble. There is a very marked purplish discoloration (cyanotic erythema) of the whole body. This discoloration disappears upon pressure and returns very slowly. The extremities are cold. There has been no return of vomiting or diarrhœa."

Death ensued at 10.30 A.M., apparently due to cardiac failure secondary to drop in blood pressure. Respirations during the last three hours of life were at the rate of 48–54 per minute.

Note.—Patient stated that he had suffered during the past four or five years from periodic attacks of vomiting at three or four weeks' interval, always accompanied by bloody diarrhœa.

Autopsy.

Autopsy performed four hours post mortem; body is that of a well-developed, well-nourished man of, apparently about 30 years of age. Rigor mortis is moderate. Lividity is excessive, except over the centre of chest and abdomen. There is œdema of both pectoral regions (subcutaneous saline). Wounds are trivial.

Thymus is completely atrophied.

Thyroid is somewhat enlarged and contains a few minute cysts filled with colloid.

Peritoneal cavity: There is a normal amount of clear fluid, lymph nodes are larger than normal, those in the gastro-colic omentum are deep-red in colour. Appendix normal. Vessels (veins) of splanchnic area are moderately distended with fluid blood, especially those draining duodenum and the upper part of the jejunum.

Pleural cavities: Both cavities are obliterated by moderately dense adhesions.

Pericardial cavity: Negative.

Lungs: Owing to the pleural adhesions present the lungs were squeezed considerably in the process of removal. The lungs are, nevertheless, voluminous and downy, except over the posterior parts, which are boggy and dark in colour. The lungs are reddish-grey in colour and are covered over the whole surface with innumerable subpleural collections of deep purple-coloured blood. These patches vary in size from 1·5 to 5 mm. (Note: These hæmorrhagic patches are typical of those found in anaphylaxis in the guinea-pig.) Beneath the parietal pleura there is a smaller number of similar hæmorrhagic spots. The cut surface of the posterior parts exudes a considerable amount of bloody frothy fluid; the anterior portions show a dilatation of the alveoli and numerous small purplish-red spots.

Heart: Normal in size and shape. The right ventricle, especially, is filled with dark fluid blood and loose friable clot. Myocardium and endocardium are negative. Beneath the epicardium covering the auricles there are numerous small purplish spots measuring from 1 to 2·5 mm. in diameter.

Liver: Purplish in colour, normal in size and consistence. Cut surface exudes an increased amount of fluid blood. The gall-bladder is slightly distended.

Spleen: Weight about 150 g., exudes upon section a moderate amount of blood. The splenic vein is distended with fluid blood.

Pancreas: Negative, except for serous congestion.

Adrenals: Negative.

Kidneys: Congested.

Bladder: contains straw-coloured urine.

Stomach and intestine: The gut contains bile-stained fluid fæces. No blood is present. Solitary follicles are prominent. Peyer's patches are not enlarged. There is moderate superficial capillary engorgement in the stomach, particularly about both orifices.

accompanying table to show the evidence on the main points, and from this evidence certain facts emerge.

1. No response was obtained on stimulation of the nerve in any case of complete division.

2. Cases of severe injury amounting to obvious destruction of more than half the cross-section of a nerve showed some response to stimulation in a fair number of instances, and the response was in general diminished after dissection was complete. Sometimes this would suggest that the dissection had divided a few surviving fibres that were much involved in scar tissue but still physiologically active.

3. Among these and other fairly severe cases one or two were noticed which seemed to show fatigue or diminished activity, either as a result of much manipulation or of much stimulation. These were not numerous enough to dogmatise upon, but suggest a line for further investigation.

4. Conductivity when present may be of normal or diminished quality.

5. A muscular contraction in response to stimulation of the central portion of the nerve is proof not only that conductivity is present through the area of injury, but also, of necessity, that it is present in the whole peripheral portion of the nerve. Nevertheless, it is possible to have in this lower portion a diminished or even absent excitability to such stimuli as are applied in this method, although the nerve can conduct an impulse from above.

6. In the two cases where slight division was the predominant feature each gave response, one showing improvement of excitability but diminished conductivity after dissection.

7. The scar cases were, of course, a mixed set, including those which showed no macroscopic evidence of section of fibres and a greater or less degree of fibrous formation about the nerve trunk. The greater number showed a conductivity more or less preserved (19 out of 26 examined), while 20 out of 31 showed excitability. Both qualities were in general improved after neurolysis; only 1 case showed a diminution, and this was of conductivity.

8. It is only with a fairly sound nerve that anything like a general contraction of the whole muscle group is seen. Mostly one gets only a contraction of one or two larger muscles. This is a drawback in estimating the condition of the nerve from the results seen in such a state as partial division, as the contraction produced does not necessarily mean that no fibres have been divided.

9. It is easy when stimulating a seriously injured nerve to get a contraction of muscles supplied by a neighbouring healthy nerve, somewhat as is seen in ordinary clinical muscle testing. This spreading of stimulation is lessened if the nerve is held up on a hook away from other tissues, so that the maximum intensity of the current is applied to the nerve, and can only get to neighbouring tissues through its long axis.

10. It has been very instructive to examine, treat, and report on cases before operation, and then to go and see what condition was actually found on the table. It has also been a help, in deciding on the course of treatment after operation, to know exactly what has been done.

11. For these reasons, and because he has the responsibility of the greater part of the period of treatment in these cases, the electrotherapist should collaborate closely with the surgeon and should attend the operations on his patients whenever possible.

12. One way in which the experience of this series has been of interest is in the light it has thrown on the accuracy of diagnostic methods and their interpretation. The reports from the electrical department endeavoured to indicate the probable degree of injury (complete division, much scar tissue, division of a few fibres only, &c.) and comparison of the opinions given in reports before operation and the actual findings shows the following results: Diagnosis correct, 41 cases; approximately correct, 18; about half right, 11; about a quarter right, 1; quite wrong, 1. The error was due to optimistic interpretation in 13 cases and five times to pessimism.

Conclusions and Lessons.

(1) Every case should be tested, as a fair number of decisions are made easier by the information obtained and an unnecessary section of an undivided nerve may be thereby avoided. This was strongly brought home in a recent case, not included in the series, where the median nerve had been exposed high in the axilla. The surgeon, his assistant, and I all felt the mass of scar tissue into which the nerve was traced, and all thought we detected a definite end to the nerve course. On stimulation, however, contraction was obtained. Without this demonstration it is quite probable that the nerve would have been divided at its apparent cut end in order to make further dissection simpler.

(2) Conductivity is conclusive evidence of physiological continuity of nerve fibres, as also is excitability below the lesion.

(3) Improvement in conductivity or in peripheral excitability following immediately after neurolysis is suggestive of only slight compression and possibly chemical nerve-block.

(4) Absence of conductivity and of excitability, even after neurolysis, is not conclusive evidence of division, but is probably an indication of fairly severe nerve disturbance.

I have to express my thanks for the ready kindness of the surgeons who have allowed me to make my investigations while they operated: Major H. Makin and Captains G. Owen and J. McGee, of the Australian Imperial Force; Majors A. Paling, M. G. Riches, and A. F. Stabb, and Captain Lawson Whale, of the R.A.M.C.; and Mr. W. S. Fenwick and Mr. R. Warren, who were consulting surgeons to Horton War Hospital. I have also to thank Lieutenant-Colonels J. R. Lord and S. Elgee, R.A.M.C., officers commanding the two hospitals, for kind permission to publish this paper.

FATAL ANAPHYLAXIS

FOLLOWING THE PROPHYLACTIC ADMINISTRATION OF ANTITETANIC SERUM.

BY FRASER B. GURD, M.D MCGILL,
AND
E. EMRYS-ROBERTS, M D LIVERP.

THAT the parenteral introduction of foreign protein in the form of antisera is not infrequently accompanied by more or less important constitutional and local manifestations of irritation or intoxication is generally appreciated. Fortunately, such symptoms consist, as a rule, simply in the development, a few (2 to 14) days after the injection, of urticarial and erythematous eruptions, and joint or muscle pains, accompanied sometimes by a certain degree of pyrexia. The patient is often very unhappy, but otherwise such examples of serum sickness are not of sufficient importance to contra-indicate the employment of sera for either prophylactic or therapeutic purposes.

From time to time, during the past 15 years, cases of severe and fatal reaction following the administration of horse serum have been recorded. The great majority of these cases have occurred among patients receiving the serum in the treatment of their infections. In the prophylactic injection of antitoxin-containing sera—e g., antidiphtheritic and antitetanic sera—the amount of protein introduced is relatively very small and the material is commonly injected into the subcutaneous tissues. In consequence very few serious accidents have occurred.

Report of Case.

The case reported in this paper proves the possibility of a fatal reaction to the administration of horse serum in small doses. This case is reported, not as an objection to the routine injection of all wounded with antitetanic serum, but rather in order that a rare clinical accident may be placed upon record.

L./Sgt. E. was admitted to a casualty clearing station on Sept. 1st, 1916, at 10 15 A M. A few hours previously he had received several small bomb wounds of both hands, the right thigh, and left calf. All wounds upon examination were found to be unimportant. The patient was in good general condition; he was a well built man about 30 years of age. Pulse and temperature were normal.

As the patient had not received his antitetanic serum prior to admission, this was administered at 11.15 A.M. 750 units (U.S.A.) contained in 5 c cm. of serum were injected subcutaneously over the right pectoralis major muscle. (There is the possibility that part of the serum was injected into the muscle.) The patient remained well until 1.30 P M., two and a quarter hours after the serum inoculation, at which hour he commenced to vomit, and had a bloody diarrhœa. This gastro-intestinal disturbance was accompanied by a moderate degree of collapse. Between 1 30 and 5 P M. he vomited eight times, and had six bowel movements. All bowel evacuations contained blood. The stools were watery, and contained small particles of fæces, and a moderate amount of small blood clot. The sister in charge of the case noted no blood in the vomitus.

Examination at 5 P.M resulted in the following notes "Pulse 104, temp. 102·8° F. Patient complains of moderate headache and thirst. There is slight generalised abdominal tenderness, no rigidity. The chest is negative, no complaint of respiratory distress, despite the fact that he is cyanosed and restless. The skin is 'goose-fleshed,' and covered with a mild erythema." From 5 P.M. to 11 P.M. the patient remained in this state of moderately severe collapse. He received water by mouth, otherwise no treatment was instituted, as his condition was not alarming.

At 11 P.M., after a slight vomiting attack, the collapsed state became very severe. He became pulseless at the radials, heart beat rose to 160–170. Extreme cyanosis supervened, and restlessness increased. During the night stimulation was pressed to the utmost. Pituitary extract, 1 c cm. to the dose, was given every three hours Strychnine, 1/30 gr., was given at 11 P M., and continued in doses of 1/40 gr. every three hours He received 3 pints of saline subcutaneously during the night, and oxygen almost continuously up to the time of death. Except for the fact that he became quieter and more comfortable while receiving oxygen, there was no response to stimulation

At 6 A M. on Sept. 2nd the following notes were made "Pulse is absent at the wrist, heart rate 180 and feeble. There is a very marked purplish discoloration (cyanotic erythema) of the whole body. This discoloration disappears upon pressure and returns very slowly. The extremities are cold There has been no return of vomiting or diarrhœa "

Death ensued at 10 30 A M, apparently due to cardiac failure secondary to drop in blood pressure. Respirations during the last three hours of life were at the rate of 48–54 per minute.

Note.—Patient stated that he had suffered during the past four or five years from periodic attacks of vomiting at three or four weeks' interval, always accompanied by bloody diarrhœa.

Autopsy

Autopsy performed four hours post mortem, body is that of a well developed, well nourished man of, apparently about 30 years of age. Rigor mortis is moderate Lividity is excessive, except over the centre of chest and abdomen. There is œdema of both pectoral regions (subcutaneous saline) Wounds are trivial.

Thymus is completely atrophied.

Thyroid is somewhat enlarged and contains a few minute cysts filled with colloid

Peritoneal cavity · There is a normal amount of clear fluid, lymph nodes are larger than normal, those in the gastro colic omentum are deep red in colour Appendix normal. Vessels (veins) of splanchnic area are moderately distended with fluid blood, especially those draining duodenum and the upper part of the jejunum

Pleural cavities Both cavities are obliterated by moderately dense adhesions

Pericardial cavity Negative

Lungs Owing to the pleural adhesions present the lungs were squeezed considerably in the process of removal. The lungs are, nevertheless, voluminous and downy, except over the posterior parts, which are boggy and dark in colour. The lungs are reddish grey in colour and are covered over the whole surface with innumerable subpleural collections of deep purple coloured blood. These patches vary in size from 1·5 to 5 mm. (Note · These hæmorrhagic patches are typical of those found in anaphylaxis in the guinea pig.) Beneath the parietal pleura there is a smaller number of similar hæmorrhagic spots. The cut surface of the posterior parts exudes a considerable amount of bloody frothy fluid; the anterior portions show a dilatation of the alveoli and numerous small purplish-red spots

Heart: Normal in size and shape The right ventricle, especially, is filled with dark fluid blood and loose friable clot. Myocardium and endocardium are negative Beneath the epicardium covering the auricles there are numerous small purplish spots measuring from 1 to 2·5 mm. in diameter.

Liver. Purplish in colour, normal in size and consistence. Cut surface exudes an increased amount of fluid blood. The gall bladder is slightly distended

Spleen. Weight about 150 g, exudes upon section a moderate amount of blood. The splenic vein is distended with fluid blood

Pancreas. Negative, except for serous congestion.

Adrenals · Negative

Kidneys: Congested

Bladder: contains straw-coloured urine

Stomach and intestine The gut contains bile stained fluid fæces. No blood is present Solitary follicles are prominent. Peyer's patches are not enlarged. There is moderate superficial capillary engorgement in the stomach, particularly about both orifices.

Naked-eye diagnosis: "Anaphylactic lungs"; congestion of kidneys; chronic pleurisy; congestion of liver; multiple wounds (trivial); slight splanchnic dilatation.

Examination of heart's blood negative.

Microscopical Examination.

Examination of paraffin-embedded sections of heart, kidney, liver, mesenteric lymph nodes, and jejunum all negative but for a moderate to pronounced congestion of the small vessels, particularly in the liver, kidney, and lymph nodes.

Sections of the lung stained with hæmatoxylin and eosin and with fibrin stain reveal the following lesion. The general appearance of the sections is irregular. Different parts of the sections are composed of varying abnormalities of alveolar arrangement. In places the alveoli are compressed, their lumina being almost obliterated; in others they are greatly distended, with apparently a rupture of their walls, with the result that large irregular cavities are present. Some of the sections are composed chiefly of masses of blood clot, in which are included numerous large and small vacuoles (air bubbles). With the high power of the microscope these areas are found to represent places in which the normal alveolar arrangement is disorganised, the alveolar walls ruptured, and the resulting irregular cavities filled with red blood cells, fibrin, and serum. The arteries of the lung are normal in size and contain red blood cells; the veins are moderately distended with blood. The bronchioles are apparently contracted and many contain large numbers of red blood cells.

Discussion.

In so far as we are able to discover, the patient had not been previously wounded, nor had he received at any other time injections of horse serum. That he was an individual presenting a natural hypersensitiveness to horse serum is therefore a fair assumption. The fact that the same person is not infrequently sensitive to more than one foreign protein in all probability offers an explanation of the patient's history of repeated attacks of vomiting and bloody diarrhœa.

The foregoing case-report is that of a healthy man who collapsed following the hypodermic administration of a relatively small dose—5 c.cm.—of horse serum, and who died with symptoms during life identical with those which occur in anaphylactic shock in the dog, and with autopsy findings typical of those which are found in the guinea-pig. That the characteristic purplish congestion of the splanchnic area which is found at autopsy in dogs dying of anaphylactic shock was not more marked in our case is explained as being the result of the continuous stimulation employed in our effort to save the life of the patient.

That symptoms of respiratory spasm were not noted clinically is explained in part by the fact that, owing to pressure of work, the patient was not under constant supervision, and, more particularly, because the splanchnic reaction was predominant and so weakened the patient that expiratory dyspnœa was not sufficiently evident to be noted by the sister in charge of the case. Deficient oxygenation of the tissues during life was evidenced by the extreme degree of cyanosis.

It is now definitely established that man reacts to anaphylactic shock in one or other or both of two ways, in addition to the well-known cutaneous phenomena. Either he reacts in the manner which characterises the phenomenon in the dog—i.e., splanchnic dilatation, drop in blood pressure, cardiac failure, and death—or in the way in which the typical reaction occurs in the guinea-pig—i.e., bronchiole spasm, expiratory dyspnœa, and death from arrest of respiration.

OXYGEN AND AIR REPLACEMENT OF FLUID IN THE PLEURAL CAVITY.

BY F. G. CHANDLER, M.D. CANTAB., M.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST.

THE apparent complexity of the apparatus commonly employed for oxygen replacement may be the explanation of its infrequent performance. The following is a description of a simple method. All that is required is a Potain's aspirator or a home-made substitute for this, two bottles A and B, and an oxygen cylinder. The aspirator and bottles can easily be improvised. The method of making the latter is obvious, and the former can be made by using a bottle, similar to those figured but larger, with a Higginson's syringe fastened to the short tube, the action of which will give sufficient negative pressure.

One of the bottles (A) is fitted at (O) with a flexible rubber tube about 18 in. in length and a needle long enough to enter the pleural cavity, with a bore of 1 mm. to allow the easy escape of air. Morriston Davies's needle, made by Krohne and Seseman, is figured, as it is useful to have a tap, but an ordinary needle will do so long as the bore is of a sufficiently large diameter. The long tube is tapered slightly at (1). Bottle (B) is fitted at (3) with 2 or 3 in. of rubber tubing, which, when required, can be slipped on to the conical part of the long tube (1) of bottle A, and thus connect the two bottles. The long tube of this second bottle is also slightly tapered, so that a rubber tube from the oxygen cylinder can be pushed on with ease. Each long tube near the external opening can, after sterilising, be lightly packed with cotton-wool. The bottles are one-third filled with 1 in 20 carbolic acid solution.

To aspirate by means of automatic air replacement is very easy, and has been described in Halliday Sutherland's "Pulmonary Tuberculosis in General Practice."

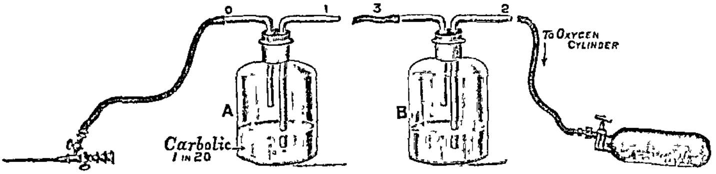
The needle of the Potain's or home-made aspirator is inserted in the seventh or eighth interspace, just outside the line of the angle of the scapula, after first anæsthetising the track with novocaine. Complete local anæsthesia should always be assured. After withdrawing a certain quantity of the fluid—say, 10 oz.—insert the needle of bottle (A) into the interspace above, again using novocaine freely. At once, with certain exceptions which will be mentioned later, air will be drawn through tube (1), bubble through the carbolic solution, and enter the pleural cavity.

Aspiration is now continued until the chest is completely emptied, allowing the patient to recline more and more as the fluid decreases, so that at last the aspirating needle is in the most dependent part of the pleural cavity. So long as aspiration is continued air will steadily flow into the pleural cavity bubbling pretty regularly through the bottle. When all the fluid has been aspirated a bubbling hissing noise will indicate that air only is being withdrawn, and the operation can cease. It is well to leave a slight negative pressure; a little of the air, therefore, is aspirated, but not enough to produce the slightest discomfort to the patient. The needles are then withdrawn.

For oxygen replacement fill both bottles (A and B) with oxygen from the cylinder. Any type of cylinder will do. Commence aspirating as before, insert needle of bottle (A) and note the rate at which bubbles of air pass through the carbolic solution and the size of them. Now turn on the oxygen cylinder which is attached to bottle (B) and let the gas bubble through at the same rate that air is bubbling through (A). This is easily determined in a few seconds. Now connect bottles (A) and (B) and continue aspirating. Pure oxygen will now be passing into the pleural cavity. To prevent the production of a positive pressure in the chest disconnect the two bottles from time to time and see if air is still drawn bubbling through bottle (A); if this is so there is, obviously, still a negative pressure and the oxygen bottle can be connected again. The small amount of air that enters does not matter. If, on disconnecting the two bottles, air does not bubble through (A), then keep them disconnected. Let the oxygen flow but escape into the air and continue to aspirate. Soon air will again be drawn through (A) and the oxygen bottle is again connected. This test of intrapleural pressure must be made from time to time.

Exceptions to Flow of Air.

The exceptions mentioned above, in which air does not flow into the pleural cavity, are as follows. The effusion may be under a positive pressure. This is unusual even when the fluid amounts to as much as seven or eight pints. Should it occur, however, aspiration must be continued until it is rendered negative; meanwhile, the rubber tube of the air needle can be clamped or bent, freeing it from time to time to discover by bubbles of air when this has been effected. It is because of these cases that it is necessary to commence aspirating before inserting the air needle, otherwise fluid will be forced into the air bottle and contaminate it, and also block the air needle. Another, though unlikely, reason for air not flowing is that the needle is not in the pleural cavity. The last and most important reason is that the air tube or needle contains fluid. These must be absolutely dry and free from bubbles. It might be thought that the thoracic suction would be sufficient to clear the tube, but in practice it will be found that this is frequently not so.



Advantages of Air or Oxygen Replacement.

So excellent and weighty are the reasons in favour of air or oxygen replacement that it would seem hardly necessary to restate them. Yet some do not know of the method, others think it neither useful nor necessary, and few employ it. I am not sure that pure oxygen has much advantage over air, except possibly for a greater curative effect. It is absorbed quicker, but the gaseous exchange that occurs leaves, after a time, a state of affairs somewhat similar in either case. The more rapid initial absorption of oxygen, however, will promote a more rapid initial expansion of the lung, if it is capable of expanding. But that one method or the other is very valuable I am convinced, and for the *following reasons*, many of which are given in Morriston Davies's "Recent Advances in the Surgery of the Lung and Pleura" (*British Journal of Surgery*, 1913) and elsewhere.

1. It is the only method by which a pleural effusion can be completely withdrawn. This is absolutely proved by radioscopy. The necessity for the *complete* evacuation, in every case, of a large serous effusion is perhaps disputable, and will not be discussed here, though I believe it to be the best treatment. If the effusion is blood, however, complete withdrawal is advisable so as to prevent the possible, and in some cases certain, onset of septic hæmothorax. In the Statistical Reports No. 5, Medical Research Committee, "On Penetrating Wounds of the Chest," in paragraph 7, "On Infected Hæmothorax," it is stated: "We aspirate the pleural cavity as dry as possible." It is impossible to get it anything like dry except by air or oxygen replacement, and if this method has been employed the "repeated aspirations" might have been prevented. If the effusion is purulent or sero-purulent then, of course, it is essential to get rid of all of it. A pneumococcal empyema *may* clear up entirely by simple aspiration, but in these cases there is a residuum of pus which must be absorbed; and, moreover, it is dangerous to advocate any method which does not involve complete drainage or complete removal of the pus. The application of the method of replacement, however, in the treatment of empyema will be dealt with more fully later.

2. It is infinitely safer to aspirate effusions by the method of replacement. No pressure changes are created in the thorax, and the accidents which may happen with ordinary aspiration—hæmorrhage from lung or pleura, sudden death by syncope, cough, albuminous catarrh, rapid re-accumulation of fluid—do not occur.

3. It is far more comfortable for the patient. With the proper use of novocaine, which should always be freely employed, there is no pain or even discomfort, and I have on many occasions seen the patient sleep through the operation, and have withdrawn as much as 7½ pints of fluid at one time without the least discomfort or distress. This would have been impossible by any other method.

4. It is good for the subsequent X ray picture, for the detail is not obscured by fluid which has been left behind and any new growth, enlarged glands, &c., can easily be seen.

5. During the absorption of the gas steady and powerful traction is exerted on the lung.

6. Pleural adhesions are less likely to form.

7. It appears to prevent reaccumulation of fluid, and to have a definite curative value.

8. It is valuable sometimes as a preliminary to operating on a large empyema.

9. Even an empyema, especially a pneumococcal empyema, can, under certain conditions, be completely withdrawn and the unopened pleural cavity be washed out. I put this forward with diffidence, firstly lest I might appear to be forgetting the great pioneer work of Audouard, Trousseau, Clifford Allbutt and Bowditch, Hamilton Roe, Hughes, and Arbuthnot Lane, which restored to medicine the effective and forgotten treatment of this condition; and secondly because there are not sufficient statistics available to form a final and sound judgment of its value. That it is invaluable in certain cases, however, I have no doubt, and apart from certain mechanical difficulties which may arise, such as obstruction of the cannula by fibrin, it is, I believe, the operation of choice.

In fact, I would say that if a child of my own had a pneumococcal empyema I should prefer first to aspirate by means of oxygen replacement, followed as soon as possible by an X ray examination. If the chest were clear and all seemed well I should be content. If signs of fluid reappeared, or if the temperature or general condition were not satisfactory, I might try one more aspiration. If this were not successful I would have a rib resection performed, a complete washing out of the pleural cavity by some non-irritating fluid, and immediate closure of the wound.

Lavage of the Closed Pleural Cavity.

The lavage of the closed pleural cavity mentioned above, is, I believe, new, and I have not yet tried it sufficiently often to justify definite statements about it. The method is as follows:—

After complete aspiration of an effusion by air or oxygen replacement, the tube of the air-needle is clamped, and the needle (or cannula) and rubber tube of the Potain's aspirator are left in position in the chest; the bottle part of the aspirator is removed and replaced by a funnel filled with warm sterile normal saline solution, which is allowed to run into the pleural cavity. When about 8 or 10 oz. have been run in the funnel is held below the level of the bed, and by the respiratory movements and by inducing the patient to cough all the saline that has been run in can be recovered. This process can be repeated.

As an illustrative case I will mention the following:—

A lance-corporal on the Cambrai front was admitted to the casualty clearing station with an attack of pneumonia. He developed an empyema. I explored and obtained thin pus which contained pneumococci. This I aspirated by oxygen replacement, and 15 oz. were withdrawn. Two days later, fluid having re-accumulated, I aspirated again by air replacement and withdrew 1½ pints of thickish yellow-green pus. After complete aspiration half a pint of warm normal saline was run through the cannula of the aspirator into the pleural cavity. This was run out again in the manner described above and was practically clear. The X ray picture showed a right pneumothorax with no fluid at all remaining, the pleural cavity being perfectly clear right down to the limits of the costo-phrenic space. No fluid reaccumulated for many days, the temperature remained normal, and the patient was evacuated to the base.

Remarks.

As early as 1882 Robert W. Parker, in a communication to the Royal Medical and Chirurgical Society, advocated the treatment of special cases of empyema by thoracocentesis and the simultaneous injection of filtered and carbolised air, pointing out that it was a "vis a tergo" and not a "vis a fronte" that displaced the fluid, and since this time Potain and many other workers have advocated this method in one form and another as the best. In the minds of those who have used it extensively there is unanimous agreement of its value. It is curious, therefore, that it is not more universally employed. Fig. 25 in Morriston Davies's new book on "The Surgery of the Lung and Pleura" is a striking testimony to the palliative value of oxygen replacement. It is a skiagram taken one month after the oxygen replacement treatment of a tuberculous pyopneumothorax. The lung has remained collapsed, but the pleural cavity is clear and the man has been able to resume active work.

In 1917 A. G., aged 19, was admitted to the Royal Herbert Hospital, Woolwich, with a tuberculous pleural effusion. He was extremely emaciated, pigmented, bedridden, and too weak to stand. Already he had been tapped four times and 112 oz. of fluid removed, but each time it rapidly recurred. Tubercle bacilli had been found in the effusion. On May 8th, soon after admission, I performed paracentesis by air replacement and withdrew 64 oz. The patient improved, but the effusion slowly reaccumulated, and on June 12th I aspirated again, this time by oxygen replacement; 2½ pints were withdrawn. He steadily improved. A little more fluid recurred at the base, but by June 30th he was infinitely better. He could walk some distance, had gained weight, and had a good colour. The pigmentation was much less, and he was able to go to his home in Devonshire.

I have chosen this example out of many cases of serous effusion and hæmothorax successfully treated by oxygen or air replacement as it affords evidence that the method advocated is of curative value as well as of great mechanical advantage.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

A NOTE ON THE
HYDROPATHIC TREATMENT OF MALARIA.

By THEODORE ZANGGER, M.D.,
ZURICH.

IN the treatment of malaria quinine stands first and foremost; next come high altitudes and arsenic. The hydrotherapeutic treatment of malaria is hardly known and seldom practised. Dr. Strasser, of Vienna, and Dr. Ziegelrot, of Berlin,[1] have written on the subject and adduced some cases, but comparative treatment of a series of cases has so far been wanting, at least as regards the medical literature in my reach. I am encouraged by a letter from Sir Ronald Ross in THE LANCET of Jan. 3rd to recall a series of cases which I treated three years ago.[2] He writes: "I wish we could cure all cases outright (with quinine); relapses ought not to be allowed to recur at all."

During the summer months of 1916 I had 82 convalescent German interned soldiers under my care in the Somvix Valley, above Disentis (Grisons), altitude 1300 m. = 4264 ft. Eighteen still suffered from malaria contracted in Corsica and Algiers; several were very anæmic and emaciated from underfeeding. They had all had lengthy consecutive courses of quinine treatment in French camps, and had already been two months at this invigorating health resort, still under quinine treatment. I discontinued the quinine and gave the patients the tepid "half baths" already described by me in THE LANCET.[3] The arms, legs, and chest of a patient lying in a bath half filled with tepid water (82° F) are rubbed for five minutes in the water, then dried, and the patient is put to bed Ambulant cases can rest for an hour and then return home These baths were repeated three times a week for three to four weeks, the average of baths per patient being eight The malaria came to an abrupt termination within 10 days During five weeks only five attacks were noted, my successor at Somvix saw two abortive cases (T under 101°), and all the 18 cases except one, who had one single slight feverish attack, were free from fever for the year during which they remained under observation I may add that Dr Brand[4] had similar results in typhoid fever

---

[1] Blätter für klinische Hydrotherapie, September, 1897.
[2] Annals of the Swiss Balneological Society, Heft xiv.
[3] THE LANCET, 1902, i., 1826.

The following table shows the number of severe malarial attacks per month in 18 cases under different treatments —

		Attacks per month
1	In Corsica and France under quinine treatment (140 days)	107
2	In Somvix (alt 1300 m) under quinine treatment (60 days)	6
3	In Somvix with tepid bath treatment and without quinine (35 days)	5

The general health of all the patients rapidly improved, while the anæmia disappeared If this treatment does not appear too simple for my English colleagues to try, I should be glad to hear if any of the 14,000 (or more) patients still suffering from malaria in England profit thereby

A LARGE URETERAL CALCULUS ASSOCIATED WITH PYONEPHROSIS

BY R LEONARD LEY, M B, B C CANTAB,

ASSISTANT SURGEON GREAT YARMOUTH HOSPITAL

THE patient, a married woman, was admitted into Great Yarmouth Hospital on Feb 2nd with a large tumour of the right flank I saw her on admission, when she gave a history of increasing debility and latterly pain in the right side of the abdomen Debility had been present for about two months and pain for a fortnight She had had to get up at night about three times to micturate for a period corresponding roughly with the period of debility. She had hæmaturia about 12 years ago, but no symptoms since then until present illness

Examination —On examination she had a large fluctuant tumour reaching from the right loin to well below the anterior superior spine The tumour had the shape of the kidney moved on respiration, and was not tender No pus or blood in urine Pulse rate 118 Temperature normal in morning up to 99 6° to 101° F at night I took a radiogram next day and found a large stone at level of sacro iliac synchondrosis Diagnosis, large ureteral calculus with hydronephrosis

Operation (Feb 7th) —Patient was put in the usual position for nephrectomy and an incision made from angle of twelfth rib and spine down to a point 1 in internal to anterior superior spine, and thence parallel to Poupart s ligament and 1½ in above it to just beyond point where the deep epigastric (which was cut) passed upwards The kidney was first exposed and separated back and front, starting from above and working down wards, it was fairly adherent and below the peritoneum was freely opened, and at the same moment as this was recognised the tumour burst and much pus escaped The patient was at once turned over on her back, packs inserted, and the pus mopped clear The stone could now be felt, and I cleared it and the ureter as rapidly as possible from the underlying iliac vessels, until I had got sufficient ureter free below to clamp it The ureter was then caught in ovariotomy clamps and divided, this left the kidney attached only on its inner surface by a broad narrow pedicle This was rapidly divided by scissors and swab pressure until the renal vessels were reached, these were found near the top of the tumour, and were clamped and divided The peritoneum was swabbed out and carefully sutured a long tube put in retroperitoneally down to the ureteric stump which was ligatured, and the wound closed in layers the tube was brought out near the top of the wound The kidney must have contained about two pints of pus

On examining the specimen the stone was found tightly gripped by the much thickened ureter, which was removed with difficulty The lower part was dry, dark and shiny, and the upper part covered with a cap of phosphates, soft and mushy on top, so that quite a lot of sand was left behind when the stone was finally shelled out The stone was 3 in in length and 4 in in girth It weighed 2 oz 2 drs

The patient left the hospital in much improved health, with the wound completely healed, on March 15th

RUPTURE OF AN AORTIC ANEURYSM INTO THE PULMONARY ARTERY

BY W E PEACOCK, M D DURH

THOUGH many cases die from the exhaustion caused by the pressure and erosion before the sac ruptures, and not a few from some other disease it is agreed that death from aneurysms of the thoracic aorta is generally sudden and caused by rupture of the sac Rupture of the ascending aorta commonly takes place either externally, into the pericardial cavity, into the right pleural sac, into the right bronchus, or, more rarely, into the superior *vena cava or pulmonary artery*

The post mortem examination of the following case showed rupture into the pulmonary artery

I was first called in to see the patient a few minutes before death occurred and found a well nourished woman, aged 67 She was livid in appearance and obviously seriously ill her pulse was small, inter mittent, but not quickened Ten minutes after my arrival she died It appeared she had been suffering from a cough and pains in the chest for six months previously, during which time she had been carrying on her ordinary housework She was the mother of several children and before her cough commenced had been doing hard manual work, pushing a milk wagon from house to house Only an hour previous to my being sent for she had been out shopping when she began to "feel ill and unable to proceed alone, so that she was assisted to her home

An autopsy was obtained and an aneurysm of the ascending aorta, about the size of a Tangerine orange, discovered communicating with the pulmonary artery about an inch above its origin The communication would admit a large quill and its margins were formed of organised blood clot There was no blood in the pericardium the lungs were deeply congested and the aorta showed marked patchy atheroma The brain was deeply congested, and one kidney somewhat granular and contracted all other organs normal

Up to the present there are about 50 recorded cases of rupture into the great veins of aneurysms of the ascending aorta, or of the aortic arch, and J B Herrick has recently described a case in which the sac communicated with the left innominate vein It is surprising that many of these cases have not ended in sudden death Herrick s case lived for six weeks while Strickland Goodall and Kingsbury have recorded a case of rupture into the left pleural cavity in which death did not occur until over five weeks afterwards when the patient suddenly fell back dead

Medical Societies.

MEDICAL SOCIETY OF LONDON.

RE-EDUCATION OF THE AMPUTATED.

A MEETING of this society was held on March 22nd, Mr. V. WARREN LOW, the President, being in the chair.

Mr. E. MUIRHEAD LITTLE read a paper on Re-education of the Amputated. Physical re-education of the maimed, he said, might be attempted by means of massage and active and passive movements of what might be called a factitious nature, or by the performance of actual work, or by the two combined. Experience had shown that although the artificial methods might alone be practicable at first, yet the sooner actual work or play were substituted the better the result. The man set to dig or do simple carpentry could continue to do so without fatigue much longer than he could repeat dull and uninteresting movements with the Zander machine. The nerve centres were far better occupied and consequently redeveloped in the purposive efforts of work. The best way to develop stump muscles was to wear and use a prosthesis; thereby the useful muscles would be developed, while those which, owing to loss of the segment to which they were attached, had ceased to be of use would be allowed to atrophy.

To obtain the best results from the natural method of training, the efforts of the patient must be supervised and intelligently guided by instructors, who, whenever possible, should have been similarly mutilated. As a general rule the disabled man should be retrained for his old trade. There was a general consensus of opinion in France that the most suitable occupation for all kinds of maimed is agriculture in its widest sense. It must be remembered that 60 to 70 per cent. of the French wounded were employed upon the land before the war; it had even been found possible to train blind men so that they could resume work among the vines, and many blind men had been returned to other kinds of land work. Great efforts have been made in France to prevent the wounded agriculturists from drifting into the towns. Amar has devised and elaborated apparatus, such as the ergometric cycle, for the exact measuring and graphic recording of work done by the respiratory and limb muscles in various kinds of labour, for showing fatigue, and even for detecting malingering, and his experience had been that 80 per cent. of war cripples were capable of re-education and 65 per cent. could be re-educated unconditionally. The remainder needed specially adapted tools, machines, or workshops.

Importance of Temperament.

The temperament of the patient was almost more important than the stump. Some men were determined to make good; others would not try. This, though true of leg cases, was more evident in arm cases. A man who had one sound hand would learn to do everything possible with that hand and would not use a prosthesis if he could help it. At Queen Mary's Convalescent Auxiliary Hospitals the first attempts at occupational training of the amputated were begun under the direction of Mr. Dudley B. Myers in 1915. The duration of the men's stay was then too short for complete technical training, but long enough to enable their capabilities and aptitudes to be discovered, and often to lay a good foundation for subsequent education. It had been astonishing to note how in a few weeks some men developed manual skill, commonly supposed to be only attainable after years of apprenticeship. When these men had been fitted with their limbs they were passed on to the Polytechnic, the Cordwainers' Technical College, Clark's Commercial College, and other centres to complete their training. The subjects taught at Roehampton included commercial training, motor mechanism, metal turning and fitting, electricity, wood-working, boot-making and repairing, and basket-making. Training in light leather work and, lectures and demonstrations on poultry-farming were given, but were abandoned for want of sufficient support. All those who had lost the right hand were taught to write with the left. To quote Mr. Myers's report:—

> "An analysis of the applications received for training shows that over 60 distinct occupations were dealt with by the employment bureau and educational workshops. No fewer than 46 per cent. of the amputated at Roehampton returned to their own employment, while training or employment involving in most cases an entire change of vocation was arranged for a further 21 per cent. The remaining 33 per cent. were passed on to the local committees to be dealt with, being themselves unwilling to consider work or to accept training except in the vicinity of their own homes."

The work done at Roehampton and at Brighton was the model on which the Ministry of Pensions had formed its training scheme.

The subject of re-education of the amputated was naturally divisible into two sections: (*a*) the re-education of the remaining parts of the amputated limb so that it might again be used with or without, but generally with, a prosthesis; (*b*) the education of the sound limb so that it might take the place and discharge the functions of the lost part. A further subdivision was concerned with the region affected, either the upper or the lower extremity; and in the case of the upper extremities the loss of both hands so profoundly affected the problem that such cases called for special consideration.

Temporary prostheses or provisional limbs are useful in themselves, and also as a means of training and development. In the case of the lower extremity, they were too much neglected in this country in the earlier years of the war, and in the case of the upper extremity they had been, and were still being, very little used. This was a pity, for no doubt many a patient, before arm-training schools were instituted, became discouraged, and discarded his artificial arm because his stump muscles had atrophied from disease, and were temporarily unequal to the task imposed upon them.

Complications.

The re-education of the amputated might be hindered by many complications, among which were: (*a*) paralysis of the stump; (*b*) ankylosis or other defect of the remaining joint or joints—e.g., flail joint; (*c*) multiple amputation; (*d*) injuries and disabilities of the sound limb; (*e*) blindness. Such complications were more difficult to deal with in the case of arm than of leg amputations. Loss of sight had not prevented St. Dunstan's from teaching arm amputees to do cabinet-making, type-writing, poultry-farming, &c. In the case of leg amputees, there were fortunately few examples in which any of these complications had absolutely prevented the patients from walking with artificial limbs, more or less well, but their re-education demanded patience, perseverance, and time.

In the earlier years of the war the number of cases was so great that the authorities, who did not properly realise the necessity of training in the use of artificial limbs, did not allow any time for this purpose. The statistics as to the usefulness of arms, which were obtained by circularising the pensioners, were so discouraging that the War Office, on the advice of the surgeons on the Advisory Council on Artificial Limbs of the Ministry of Pensions, ordered that every man who was provided with an arm prosthesis should spend at least a fortnight after receiving it in being trained in its use in an arm-training school at a limb-fitting hospital. The Rev. Captain Rowlatt Maxwell, C.F., who had lost an arm a few inches below the elbow, was appointed chief arm instructor to the Ministry of Pensions. The course of instruction which he devised was first given at Charterhouse Military Hospital and afterwards at Roehampton and in the provincial centres. In all so-called mechanical arms, except those for kinematised stumps, the principles employed by Baliff in 1818 were applied. The artificial joints were moved by means of movements of the stump and the shoulders, and even of the opposite arm. To make and coördinate these movements exactly nerve centres and paths and muscles had to be adapted and developed to perform duties at first strange to them. In time a patient who constantly used his arm prosthesis made the movements as automatically as those of his sound hand. He had only to will to make a certain movement of the artificial appliance, and he did it without thinking of his shoulder, his stump, or his opposite arm, although one or other of these might do the work. Consideration of these new neuro-muscular arrangements and of the stereognostic sense as concerned in the use of prostheses opened up an interesting field of study for neurologists.

A few words might be added as to the re-education of kinematised stumps. The few cases admitted to the hospital for the supply of arms had been treated by the application of a Thomas arm splint, such as is used for fractures of the humerus. India-rubber cords were attached to the distal end of the splint and to the plastic motors of the stump, and the patients were directed to exercise the muscles of the motors by pulling against this elastic resistance. The strength and tension of the cords was easily varied. By using this simple appliance patients gained muscular power, and the motors were lengthened and mobilised before the prosthesis was applied. A pull of 20 lb. might be obtained from the combined biceps and brachialis motor, an amount, probably, far less than the effort of which these muscles were capable in their normal condition. In the mutilated limb, even after considerable training, fatigue was apt to occur sooner than normally. The tunnelised motors devised by Sauerbruch appeared to be less useful and more difficult to fit with arms than the club motors with bony nuclei made on the Vanghetti methods elaborated by Major M. Fitzmaurice-Kelly.

Arm Training: Interesting Tasks.

This course of arm training did not aim at teaching any trade or industry, but the patients developed the appropriate nervous control and muscular power by doing certain tasks which were interesting to them, and at the same time the nerve centres of the remaining sound limb learnt to adapt themselves to new tasks, and the necessary muscles were coördinated and developed. Carpentry, digging, loading and wheeling a barrow, and using a sledge hammer were the chief means of training. Each man made a number of wooden articles, and as he was allowed to take them away with him as proof of his skill he was interested in making them well. This kind of training offered far more encouragement and hope to the men than any scheme of exercises could. Naturally, amputees after many operations and months in hospital became profoundly discouraged and sceptical as to the usefulness of an arm, but when they saw what others could do, and found that they could emulate them, they regained hope and confidence.

Mr. Little exhibited average specimens of the carpentry. Most of the work, he said, was done with the sound hand, the artificial limb acting merely as an auxiliary. As these would be the respective functions of the two arms in after-life this training was on the right lines. Besides the work at the bench, those who had been fitted with workers' arms learnt to use the implements for the coarse work on the land mentioned above.

Practical Training in the Use of Permanent Artificial Legs.

This was instituted from the very beginning at Roehampton. It began in the limb-makers' workshops, where the patient was made to try the limb in the rough by walking at first between two parallel wooden rails on which he could rest his hands. At each end of these rails was a large looking-glass, in which he could see how he walked, so that he might correct errors. After the limb had been completed and the limb-maker was satisfied that it fitted, the wearer came into the hands of non-commissioned officers who had each lost a limb. He attended a number of walking parades at which his errors were pointed out and advice given for their correction. These were held in and out of doors, and included walking up and down slopes and steps, and on rough as well as on smooth ground. After a week of this training the patient was usually ready to pass the surgeon and to be discharged. If he failed to walk as well as could be expected he might be put back for further practice and instruction.

When a man had long worn a provisional peg-leg without a knee-joint he was apt to develop a bad gait owing to his having had to circumduct the stiff limb in bringing it forward. Practice and perseverance corrected this. Some men did not get on with their artificial legs from various causes, but the number who did well with them was very gratifying.

Now that about 500 or 600 pensioners a month were returning to receive duplicate limbs there were opportunities of reviewing the work done in the earlier years of the war, and a number of cases of hip amputation were seen who had been able to walk several miles (up to 10 miles) a day on their prostheses. "Solvitur ambulando" is, Mr. Little concluded, the key to the problem of re-education of the leg amputee.

Discussion.

The PRESIDENT said that before the war he had been struck by the mental and physical deterioration of men who had had amputations, and had always felt that purposive work was preferable to routine exercises in their re-education. He imagined that the first thing to do was to teach the men to be optimists; this was ensured by supplying teachers who themselves had had amputations.

Mr. LAMING EVANS thought that a point might be made with regard to the existence of a stimulus. In the class of case under discussion no legal action was pending and the men were financially secure; this aided treatment materially. In the early stages of exercises where volitional power was bad he thought the Zander method useful. Nearly all physical movements were best taught by mimicry. Many cases got on better with a forearm stump used as a single finger than with an artificial hand, and the more elaborate prostheses were often abandoned or used only for dress purposes.

Dr. J. B. MENNELL spoke of amputations above the knee. Some of these amputees took to the artificial limb instinctively and without trouble, others found greater difficulty. Among the latter a limp was apt to occur like that habitual to the one-sided tabetic. This suggested the need for training of coördination, a speculation borne out by experience. Such training was based upon the anatomy of the limb. Men who walked with crutches used them in different ways, and coördination between the muscles was variously affected. He directed his first effort to restoring coördination between the muscles, combined with restoration of muscle strength by faradism. Much might be done by teaching the patients to walk in front of a looking-glass. This was followed by training the stereognostic sense. Such treatment was laborious, and particular for each individual, and required a highly trained personnel.

Mr. E. M. CORNER said that when a nerve had been divided it was practically impossible to prevent it from growing again, and recent work had shown that organisms could thus be carried down to the stump. He quoted a case in which pain had recurred in the stump after excision of nerves and after an artificial leg had seemed to be successful. The pain was so bad that the patient travelled back from the West Indies. There was an apparent elongation of the fibula, due to irritating infective scar tissue, into which the regenerating nerves had grown. The lower end of the fibula, with the cicatrix, cutaneous and subcutaneous, below it, including the posterior tibial artery and nerve, were excised. The pain ceased and pressure over the fibula could be borne. Usually in the interval between the amputation and the fitting of the artificial limb the infective scar tissue became non-irritant and non-infective through the agency of the plasma and lymph. But occasionally the nerves grew into the scar tissue, reinfecting it by carrying organisms into it, or into scar tissue which had remained infective, so that pain returned after an interval of comfort. As nerves regenerated cultures could be obtained from a certain number of them. Whether pain recurred depended upon the patient's power to combat this infection. The degree of mental deterioration had a good deal to do with the amount of success attained. It was doubtful whether it was advisable to keep patients in hospital if what they learnt there could not be used in earning a livelihood.

Captain ROWLATT MAXWELL (C.F.) said that the first thing that had to be done in re-education concerned the psychological side. There was often much difficulty in the first few days, and a good deal of time had to be spent in encouraging the men. Their attitude was very different after being a short time in the arm-training school. There had not been much stump-training at the school, and the course was not long enough for vocational training. He was quite convinced that, were it not for the training provided, the percentage of men not using their artificial arms would be much higher. Many of those coming back as pensioners were found not to be wearing their arms because they did not know how to use them, some because they were painful, others because they thought that the pension would go if they became proficient. The training school gave an opportunity for the man to get fitted with the most suitable type of arm for him and also of having it thoroughly tested. He advocated that surgeons should pool their knowledge, find out what was being done in other countries, and combine with mechanical experts in devising suitable prostheses. Harm had been done by the exaggerated claims made in the press for the general usefulness of various forms of artificial limbs as demonstrable on specially trained men.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

EXHIBITION OF CLINICAL CASES.

A MEETING of this section of the Royal Society of Medicine was held on March 26th, Mr. J. P. LOCKHART-MUMMERY, the President, being in the chair.

Case of Hemi-hypertrophy.

Dr. HAZEL H. GREGORY showed a case of Hemi-hypertrophy. The patient, a girl, aged 2½ years, had well-marked asymmetry of the body and limbs. The condition was noticed at birth, and the mother thought that the disproportion between the two sides had not increased since. The other members of the family were similarly affected. The left upper and lower extremities, and the left side of the abdomen, chest, and tongue were all obviously larger than the right. On the other hand, the right side of the head was slightly larger than the left. The size of the right side, compared with other children of the same age, and its shapeliness, seemed to indicate that this was the normal size, and that the left was abnormally developed. The measurements were:—Arm: acromion to tip of thumb, R. 11½ in., L. 13½ in.; circumference, middle of upper arm, R. 6 in., L. 7 in. Leg: anterior superior spine to internal malleolus, R. 14¾ in., L. 15¼ in.; circumference, middle of thigh, R. 10 in., L. 11½ in. Abdomen: spine to umbilicus, R. 10 in., L. 11¼ in. Thorax: spine to mid-sternum, R. 9½ in, L. 11 in. Skull: greatest semi-circumference, R. 6½ in., L. 5½ in. The left side of the tongue and face were also larger than the right. Dr. Gregory referred to other cases, notably two recorded by Dr. R. Hutchison, in which post-mortem examination had shown that glands and lymphatic structures shared in the overgrowth. It had to be remembered that some asymmetry was the rule and had been shown to be present in 90 per cent. of normal persons.

Rheumatoid Arthritis with Nodules.

Dr. D. H. PATERSON showed a case of Rheumatoid Arthritis with Nodules in a girl aged 8. There were swelling of joints and stiffness of the neck, which had come on gradually and had been present for twelve months. Swelling of the wrists was noticed first, and in May, 1919, she was admitted to hospital and nodules were found on the elbows, in association with painful wrists and ankles. There was no heart lesion. She was regarded at that time as suffering from acute rheumatism and was treated for that condition, though the absence of heart affection in a child with nodules was commented upon. On discharge there was still a large nodule on the right elbow. Since then practically all the joints had been affected, and she had never been quite well. Before readmission in February, 1920, her neck became stiff. On readmission both wrists were thickened, and the backs of the hands were swollen the interossei were atrophied. As well as the nodule on the right elbow, there was now one on the left. The epitrochlear glands were enlarged on both sides, and there were shotty glands along the posterior border of the sterno-mastoid muscle on the right side. Other joints were not now affected. The heart was normal the spleen was not enlarged. The teeth were in good condition. The tonsils had been removed. The temperature had remained normal under observation Radiograms showed no changes. The diagnosis o fibrous rheumatism had been suggested, but it was a disease which had been described in adults, and in i the nodules were more diffuse. The Wassermann reaction was negative.

Dr. FREDERICK LANGMEAD said that in view o the character of the joint swelling, the enlargement o epitrochlear, sterno-mastoid, and axillary glands, and the negative findings by X rays he fully agreed with the diagnosis. The point which interested him was the association of the nodules. Flat, fibrous, plaque-like nodules were, of course, not unusual in rheumatoid arthritis, and were often found in the same situation but the nodules in this case were more like the nodules of acute rheumatism, and were said to vary considerably in size and to disappear quickly. Such a case seemed to support the view of those who believed that rheumatoid arthritis and acute rheumatism were due to the same infection. Rheumatoid arthritis was, however, a symptom-complex in his opinion, and capable of resulting from various infections. Perhaps the explanation of the present case was that it was one o the rare examples of rheumatoid arthritis in which the symptom-complex had followed an initial infection by the cause of acute rheumatism.

Anæmia with Splenomegaly.

Dr. PATERSON also showed a case of Anæmia with Splenomegaly in a child aged 4 months, who was under the care of Dr. F. J. Poynton. A swelling had been noticed in the abdomen for a fortnight. Since the age of 2 weeks he had been losing weight, and had always been pale. For two weeks before admission there had been loose green stools. Cardio-vascular and respiratory systems were apparently normal. The left flank was occupied by a large mass, which seemed to be the spleen, and which extended forwards to within an inch of the umbilicus and reached to the pelvic brim. The liver was also large, reaching 1½ fingers' breadth below the costal margin at the ninth rib. Lymphatic glands were not large. The stools and urine were now normal. A blood examination showed: red blood cells, 3,440,000; white cells, 18,000; hæmoglobin, 30 per cent.; colour index, 0·4. Differential count: polymorphs, 29 per cent.; small lymphocytes, 35 per cent.; large lymphocytes, 16 per cent.; transitionals, 1 per cent.; neutrophilic myelocytes, 12 per cent.: basophilic and myelocytes, 3 per cent.; normoblasts, 2 per cent.; and megaloblasts, 12 per cent. Polychromatophilia was present. The Wassermann reaction was negative. The case was regarded as one of v. Jaksch's anæmia.—Dr. F. PARKES WEBER held that considering its present size the spleen must have been enlarged at birth. The younger the child the more would one expect the blood picture to be disturbed; it was therefore not surprising to find so many myelocytes and nucleated reds.

Another Case of Splenomegaly.

Dr. PATERSON also showed a second case of Splenomegaly in a girl aged 5 years, under the care of Dr. R. Hutchison. The patient was somewhat pale and puffy, with flabby muscles and slight enlargement of the spleen and liver. The lymphatic glands were not enlarged. The girl was prone to "dirt-eating." On admission the red blood corpuscles numbered 3,680,000 and white corpuscles 7200, of which polymorphs were 46 per cent.: small lymphocytes, 32 per cent.; large lymphocytes, 19 per cent.; large mononuclears, 2 per cent.; and myelocytes, 1 per cent. The hæmoglobin was 32 per cent. and colour index 0·4. A week later the spleen was noted to be larger, the red blood cells had diminished by about one million and the hæmoglobin by 7 per cent., while the white cells had increased to 14,000. The differential count remained approximately the same, but the myelocytes had increased to 3 per cent., and 4 per cent. nucleated red cells were noted. The Wassermann reaction was negative The view was expressed that possibly the case was an example of a late stage of recovering splenic anæmia of the infantile type (v. Jaksch's anæmia)

MIDLAND MEDICAL SOCIETY.

Orthopædic Treatment in War Surgery.

AT a meeting of this society, held at Birmingham on March 3rd, with Mr. W. A Loxton, the President, in the chair, a demonstration of the results of Orthopædic Treatment in War Surgery was given, and 30 illustrative cases were shown —Dr J. F Atkins, of the Uffculme Limb Fitting Centre, described various types of artificial limbs, and emphasised the importance of the retention of as long a stump as possible, and of its preparation for a permanent limb by the use of a temporary limb or plaster of-Paris pylon. He then discussed the relative value of the various amputation operations commonly performed The results of psychotherapy in the treatment of functional contractures and loss of function were demonstrated by the medical officers from Hollymoor, Highbury, and the Out patients' Clinic, Broad street, and cases of complete recovery of function were shown.—Mr. H. H. Sampson (Hollymoor) showed the results of four cases of Arthroplasty for Bony Ankylosis of the Elbow. He had retained the epicondyles, *removing half the olecranon process, the greater portion of the coronoid process, and the head of the radius. The free flap of fascia from the thigh* was then interposed between the bone surfaces The cases showed a good range of movement with little lateral mobility. The removal of large flaps of fascia from the thigh had not in his experience resulted in muscle hernia —Captain J. A. Dickson (Highbury Hospital) showed a series of cases of tendon transplantations for partial and complete loss of power in the extensors of the wrist, fingers, and thumb. He advised this operation only when nerve suture had been found impracticable. The chief points in the operation were (1) the importance of direct pull of the muscle from its origin to its new insertion; (2) the tension at the time of suture; and (3) the complete burying of the transposed tendons in their receiving tendons —Captain Dickson then demonstrated the method adopted for gradual correction of disabilities of the wrist and hand. — Captain F. W. Stuart (Hollymoor) showed the results of bone-grafting in cases of loss of continuity of the bones of the extremities. One case was shown two years after operation. The grafted bone had assumed the size of the receiving bone, and was itself developing a medullary cavity. He emphasised the importance of the preliminary excision of scar tissue, and of making the bone graft, when used, of sufficient strength to withstand the strain of function and as long as the anatomical condition of the receiving bones would allow. Captain Stuart also showed cases to illustrate the results of Radical Sequestrotomy in the case of the Chronic Bone Sinus —Major Naughton Dunn then showed three cases, the successful treatment of which was, he said, a result of our war experience. The first was a case of an officer with ankylosis of the right inferior radio ulnar joint in a full supinated position The operation, suggested by Dr Baldwin, of San Francisco, had resulted in free complete controlled movements of pronation and supination, and consisted in removal of a portion of the ulnar just above the inferior articulation, so that the movements could take place at this false joint The second case was *the result of* arthrodesis of the humerus and scapula, *after complete* loss of the upper half of the humerus The patient had a short but strong arm, with *free controlled* movement in a certain range. The third case showed the successful treatment of a severe gunshot wound of the upper third of the thigh.

SOCIÉTÉ DE THÉRAPEUTIQUE DE PARIS.

AT a recent meeting of this society Dr. G. Rosenthal read a note on the Dangers of Autoserotherapy, which *Dr. V. Cordier* had emphasised at the last meeting.[1] He stated that these could be avoided by not reinoculating the fluid until it had been filtered. 5–10 c.cm. of the fluid diluted with an equal quantity of isotonic serum were poured into a sterile tube and then filtered through a Chamberland filter before use —In a communication on Cystalgia following the Consumption of Cress, Dr. H Leclerc reported several cases, including that of himself, in which consumption of large quantities of cress had given rise to dysuria and vesical spasm, and in one instance to priapism Examination of the urine showed no characteristic changes In only one case did the sediment reveal an abnormal amount of epithelial desquamation. The symptoms, moreover, were of such short *duration that they were apparently due to a transient irritation of the vesical mucous membrane* and not to actual cystitis. Chemical *analysis of the cress* showed the presence of iron, iodine, and a *sulpho nitrogenous* essence, to the irritating properties of which *the symptoms* were probably due The proof of this supposition *appeared to be furnished by* the fact that cooked cress, in which the *essence did not* exist, did not give rise to any symptoms. Dr Leclerc had not been able to find any description *of these* properties of cress in medical literature, but a passage in the Thesmophoriazusæ of Aristophanes showed that they were well known to the ancient Greeks —Dr. L. Rénon read a paper on the Alimentary and Therapeutical Value of Fenugreek Seeds, which he said had been employed in popular medicine from the earliest antiquity, and were still used in Egypt and Northern Africa at the present day for giving embonpoint to young women before marriage and fattening emaciated persons. Recent investigations had shown that these seeds contained most important nutritive elements They were very rich in nitrogen and phosphorus, and contained globulin, phytin, and nucleo albumin in considerable quantities. Unfortunately, besides an unpleasant taste, they possessed a very disagreeable odour, which impregnated the organism and became *diffused* in the urine and sweat Rénon and Hénissey *had been able to remedy this drawback by lixiviating the powdered seeds in* 90° *alcohol* at the ordinary temperature The *powder so treated lost almost* entirely its disagreeable odour and taste, and could be used for alimentary and therapeutical purposes. Dr Rénon had recently employed it in doses of 8–10 g daily in the treatment of convalescents from influenza —In a note on the Chemotherapy of Morphinism, Dr. A. Brissemoret and Dr. A Challamel advocated the use of berberine, associated with helenine as a demorphinisation cure. The combination of these two drugs, which presented the great advantage of being perfectly harmless, non toxic products, afforded the patient a relief comparable to that conferred by morphia, and removed the distressing symptoms caused by the deprivation of the drug.—Dr. H. Forestier read a paper on Intravenous Injection of Colloidal Sulphur in Chronic Rheumatism, with a record of six illustrative cases

THE MEDICO LEGAL SOCIETY.

Medical Investigation in Crimes of Violence.

A MEETING of this society was held at 11, Chandos street, W., on March 25th, with Mr. R Henslowe Wellington, the President, in the chair, when Dr. B H. Spilsbury read a paper entitled "Medical Investigation in Crimes of Violence" Dr Spilsbury, who illustrated his remarks by the recital of famous cases, insisted on the need for the investigation, not merely of the cadaver by the usual methods, but of the surroundings, both on the occasion of the *first discovery* and subsequently. *Such investigations, he contended, should be made by skilled medical observers* and, while the first results would be *found* of value in the performance of the subsequent post mortems, data obtained at such post-mortems would indicate the lines on which later examinations of the site of the alleged or suspected crime should be conducted —In the course of the discussion that followed Lord Justice Atkin emphasised the value of the work of the Medico Legal Society and expressed the desire that some means might be found to bring directly before coroners, chief constables, and others such points as those so ably expounded by Dr Spilsbury. His lordship also drew attention to the difficulties attending *the forensic* investigation of crimes *of violence which fell short of* murder or manslaughter —Sir William Collins, Earl Russell, Major Haden Guest, Dr W. H. Willcox, Mr. A. B. Watson, Dr. J. Maughan also spoke, and Dr. Spilsbury replied.

THE LATE JOHN MACDOUGALL CLARK, M.B., CH.B GLASG.—Dr. John M. Clark, who succumbed on March 28th to an attack of pneumonia consequent on influenza, had been for 15 months on the staff of the Pilkington Orthopædic Hospital, St Helens. After taking his medical degree in 1916 Dr. Clark acted as house surgeon in Dr. Paterson's wards at the Glasgow Royal Infirmary, when he joined the R A.M.C, and was *for two years* in German East Africa At the Pilkington Hospital, as chief of staff under Mr. J. R Kerr, the officer in charge, his whole-hearted *interest* in the efficiency of the hospital and the *welfare of the men* will be gratefully remembered.

[1] THE LANCET, Feb 7th, 1920, p 326

patients in hospital if what they learnt there could not be used in earning a livelihood.

Captain ROWLATT MAXWELL (C.F.) said that the first thing that had to be done in re-education concerned the psychological side. There was often much difficulty in the first few days, and a good deal of time had to be spent in encouraging the men. Their attitude was very different after being a short time in the arm-training school. There had not been much stump-training at the school, and the course was not long enough for vocational training. He was quite convinced that, were it not for the training provided, the percentage of men not using their artificial arms would be much higher. Many of those coming back as pensioners were found not to be wearing their arms because they did not know how to use them, some because they were painful, others because they thought that the pension would go if they became proficient. The training school gave an opportunity for the man to get fitted with the most suitable type of arm for him and also of having it thoroughly tested. He advocated that surgeons should pool their knowledge, find out what was being done in other countries, and combine with mechanical experts in devising suitable prostheses. Harm had been done by the exaggerated claims made in the press for the general usefulness of various forms of artificial limbs as demonstrable on specially trained men.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

EXHIBITION OF CLINICAL CASES.

A MEETING of this section of the Royal Society of Medicine was held on March 26th, Mr. J. P. LOCKHART-MUMMERY, the President, being in the chair.

Case of Hemi-hypertrophy.

Dr. HAZEL H. GREGORY showed a case of Hemi-hypertrophy. The patient, a girl, aged 2½ years, had well-marked asymmetry of the body and limbs. The condition was noticed at birth, and the mother thought that the disproportion between the two sides had not increased since. The other members of the family were similarly affected. The left upper and lower extremities, and the left side of the abdomen, chest, and tongue were all obviously larger than the right. On the other hand, the right side of the head was slightly larger than the left. The size of the right side, compared with other children of the same age, and its shapeliness, seemed to indicate that this was the normal size, and that the left was abnormally developed. The measurements were:—Arm: acromion to tip of thumb, R. 11½ in., L. 13½ in.; circumference, middle of upper arm, R. 6 in., L. 7 in. Leg: anterior superior spine to internal malleolus, R. 14¼ in., L. 15¼ in.; circumference, middle of thigh, R. 10 in., L. 11½ in. Abdomen: spine to umbilicus, R. 10 in., L. 11¼ in. Thorax: spine to mid-sternum, R. 9½ in, L. 11 in. Skull: greatest semi-circumference, R. 6½ in., L. 5½ in. The left side of the tongue and face were also larger than the right. Dr. Gregory referred to other cases, notably two recorded by Dr. R. Hutchison, in which post-mortem examination had shown that glands and, lymphatic structures shared in the overgrowth. It had to be remembered that some asymmetry was the rule and had been shown to be present in 90 per cent. of normal persons.

Rheumatoid Arthritis with Nodules.

Dr. D. H. PATERSON showed a case of Rheumatoid Arthritis with Nodules in a girl aged 8. There were swelling of joints and stiffness of the neck, which had come on gradually and had been present for twelve months. Swelling of the wrists was noticed first, and in May, 1919, she was admitted to hospital and nodules were found on the elbows, in association with painful wrists and ankles. There was no heart lesion. She was regarded at that time as suffering from acute rheumatism and was treated for that condition, though, the absence of heart affection in a child with nodules was commented upon. On discharge there was still a large nodule on the right elbow. Since then practically all the joints had been affected, and she had never been quite well. Before readmission in February, 1920, her neck became stiff. On readmission both wrists were thickened, and the backs of the hands were swollen; the interossei were atrophied. As well as the nodule on the right elbow, there was now one on the left. The epitrochlear glands were enlarged on both sides, and there were shotty glands along the posterior border of the sterno-mastoid muscle on the right side. Other joints were not now affected. The heart was normal; the spleen was not enlarged. The teeth were in good condition. The tonsils had been removed. The temperature had remained normal under observation. Radiograms showed no changes. The diagnosis of fibrous rheumatism had been suggested, but it was a disease which had been described in adults, and in it the nodules were more diffuse. The Wassermann reaction was negative.

Dr. FREDERICK LANGMEAD said that in view of the character of the joint swelling, the enlargement of epitrochlear, sterno-mastoid, and axillary glands, and the negative findings by X rays he fully agreed with the diagnosis. The point which interested him was the association of the nodules. Flat, fibrous, plaque-like nodules were, of course, not unusual in rheumatoid arthritis, and were often found in the same situation, but the nodules in this case were more like the nodules of acute rheumatism, and were said to vary considerably in size and to disappear quickly. Such a case seemed to support the view of those who believed that rheumatoid arthritis and acute rheumatism were due to the same infection. Rheumatoid arthritis was, however, a symptom-complex in his opinion, and capable of resulting from various infections. Perhaps the explanation of the present case was that it was one of the rare examples of rheumatoid arthritis in which the symptom-complex had followed an initial infection by the cause of acute rheumatism.

Anæmia with Splenomegaly.

Dr. PATERSON also showed a case of Anæmia with Splenomegaly in a child aged 4 months, who was under the care of Dr. F. J. Poynton. A swelling had been noticed in the abdomen for a fortnight. Since the age of 2 weeks he had been losing weight, and had always been pale. For two weeks before admission there had been loose green stools. Cardio-vascular and respiratory systems were apparently normal. The left flank was occupied by a large mass, which seemed to be the spleen, and which extended forwards to within an inch of the umbilicus and reached to the pelvic brim. The liver was also large, reaching 1½ fingers' breadth below the costal margin at the ninth rib. Lymphatic glands were not large. The stools and urine were now normal. A blood examination showed: red blood cells, 3,440,000; white cells, 18,000; hæmoglobin, 30 per cent.; colour index, 0·4. Differential count: polymorphs, 29 per cent.; small lymphocytes, 35 per cent.; large lymphocytes, 16 per cent.; transitionals, 1 per cent.; neutrophilic myelocytes, 12 per cent.: basophilic and myelocytes, 3 per cent.; normoblasts, 2 per cent.; and megaloblasts, 12 per cent. Polychromatophilia was present. The Wassermann reaction was negative. The case was regarded as one of v. Jaksch's anæmia.—Dr. F. PARKES WEBER held that considering its present size the spleen must have been *enlarged at birth*. The younger the child the more would one expect the blood picture to be disturbed; it was therefore not surprising to find so many myelocytes and nucleated reds.

Another Case of Splenomegaly.

Dr. PATERSON also showed a second case of Splenomegaly in a girl aged 5 years, under the care of Dr. R. Hutchison. The patient was somewhat pale and puffy, with flabby muscles and slight enlargement of the spleen and liver. The lymphatic glands were not enlarged. The girl was prone to "dirt-eating." On admission the red blood corpuscles numbered 3,680,000 and white corpuscles 7200, of which polymorphs were 46 per cent.: small lymphocytes, 32 per cent.; large lymphocytes, 19 per cent.; large mononuclears, 2 per cent , and myelocytes, 1 per cent The hæmoglobin was 32 per cent and colour index 0 4 A week later the spleen was noted to be larger, the red blood cells had diminished by about one million and the hæmoglobin by 7 per cent , while the white cells had increased to 14,000 The differential count remained approximately the same, but the myelocytes had increased to 3 per cent , and 4 per cent nucleated red cells were noted The Wassermann reaction was negative The view was expressed that possibly the case was an example of a late stage of recovering splenic anæmia of the infantile type (v Jaksch's anæmia)

MIDLAND MEDICAL SOCIETY

Orthopædic Treatment in War Surgery

AT a meeting of this society, held at Birmingham on March 3rd, with Mr W A Loxton, the President, in the chair, a demonstration of the results of Orthopædic Treatment in War Surgery was given, and 30 illustrative cases were shown —Dr J F Atkins, of the Uffculme Limb Fitting Centre, described various types of artificial limbs, and emphasised the importance of the retention of as long a stump as possible, and of its preparation for a permanent limb by the use of a temporary limb or plaster of Paris pylon He then discussed the relative value of the various amputation operations commonly performed The results of psychotherapy in the treatment of functional contractures and loss of function were demonstrated by the medical officers from Hollymoor, Highbury, and the Out patients' Clinic, Broad street, and cases of complete recovery of function were shown —Mr H H Sampson (Hollymoor) showed the results of four cases of Arthroplasty for Bony Ankylosis of the Elbow He had retained the epicondyles, removing half the olecranon process, the greater portion of the coronoid process and the head of the radius The free flap of fascia from the thigh was then interposed between the bone surfaces The cases showed a good range of movement with little lateral mobility The removal of large flaps of fascia from the thigh had not in his experience resulted in muscle hernia —Captain J A Dickson (Highbury Hospital) showed a series of cases of tendon transplantations for partial and complete loss of power in the extensors of the wrist, fingers, and thumb He advised this operation only when nerve suture had been found impracticable The chief points in the operation were (1) the importance of direct pull of the muscle from its origin to its new insertion , (2) the tension at the time of suture, and (3) the complete burying of the transposed tendons in their receiving tendons —Captain Dickson then demonstrated the method adopted for gradual correction of disabilities of the wrist and hand — Captain F. W Stuart (Hollymoor) showed the results of bone grafting in cases of loss of continuity of the bones of the extremities One case was shown two years after operation The grafted bone had assumed the size of the receiving bone, and was itself developing a medullary cavity He emphasised the importance of the preliminary excision of scar tissue, and of making the bone graft, when used, of sufficient strength to withstand the strain of function and as long as the anatomical condition of the receiving bones would allow Captain Stuart also showed cases to illustrate the results of Radical Sequestrotomy in the case of the Chronic Bone Sinus —Major Naughton Dunn then showed three cases, the successful treatment of which was, he said, a result of our war experience The first was a case of an officer with ankylosis of the right inferior radio ulnar joint in a full supinated position The operation, suggested by Dr Baldwin, of San Francisco, had resulted in free complete controlled movements of pronation and supination, and consisted in removal of a portion of the ulnar just above the inferior articulation, so that the movements could take place at this false joint The second case was the result of arthrodesis of the humerus and scapula, after complete loss of the upper half of the humerus The patient had a short but strong arm, with free controlled movement in a certain range The third case showed the successful treatment of a severe gunshot wound of the upper third of the thigh

SOCIÉTÉ DE THÉRAPEUTIQUE DE PARIS

AT a recent meeting of this society Dr G Rosenthal read a note on the Dangers of Autoserotherapy, which Dr V Cordier had emphasised at the last meeting[1] He stated that these could be avoided by not reinoculating the fluid until it had been filtered 5-10 c cm of the fluid diluted with an equal quantity of isotonic serum were poured into a sterile tube and then filtered through a Chamberland filter before use —In a communication on Cystalgia following the Consumption of Cress, Dr H Leclerc reported several cases, including that of himself, in which consumption of large quantities of cress had given rise to dysuria and vesical spasm, and in one instance to priapism Examination of the urine showed no characteristic changes In only one case did the sediment reveal an abnormal amount of epithelial desquamation The symptoms, moreover, were of such short duration that they were apparently due to a transient irritation of the vesical mucous membrane and not to actual cystitis Chemical analysis of the cress showed the presence of iron, iodine, and a sulpho nitrogenous essence, to the irritating properties of which the symptoms were probably due The proof of this supposition appeared to be furnished by the fact that cooked cress, in which the essence did not exist, did not give rise to any symptoms Dr Leclerc had not been able to find any description of these properties of cress in medical literature, but a passage in the Thesmophoriazusæ of Aristophanes showed that they were well known to the ancient Greeks —Dr L Rénon read a paper on the Alimentary and Therapeutical Value of Fenugreek Seeds, which he said had been employed in popular medicine from the earliest antiquity, and were still used in Egypt and Northern Africa at the present day for giving embonpoint to young women before marriage and fattening emaciated persons Recent investigations had shown that these seeds contained most important nutritive elements They were very rich in nitrogen and phosphorus, and contained globulin, phytin, and nucleo albumin in considerable quantities Unfortunately, besides an unpleasant taste, they possessed a very disagreeable odour, which impregnated the organism and became diffused in the urine and sweat Rénon and Hénissey had been able to remedy this drawback by lixiviating the powdered seeds in 90° alcohol at the ordinary temperature The powder so treated lost almost entirely its disagreeable odour and taste, and could be used for alimentary and therapeutical purposes Dr Rénon had recently employed it in doses of 8 10 g daily in the treatment of convalescents from influenza —In a note on the Chemotherapy of Morphinism, Dr. A Brissemoret and Dr A Challamel advocated the use of berberine, associated with helenine as a demorphinisation cure The combination of these two drugs, which presented the great advantage of being perfectly harmless, non toxic products afforded the patient a relief comparable to that conferred by morphia, and removed the distressing symptoms caused by the deprivation of the drug —Dr H Forestier read a paper on Intravenous Injection of Colloidal Sulphur in Chronic Rheumatism, with a record of six illustrative cases

THE MEDICO LEGAL SOCIETY

Medical Investigation in Crimes of Violence

A MEETING of this society was held at 11, Chandos street, W , on March 25th, with Mr R Henslowe Wellington, the President, in the chair, when Dr B H Spilsbury read a paper entitled Medical Investigation in Crimes of Violence " Dr Spilsbury, who illustrated his remarks by the recital of famous cases, insisted on the need for the investigation, not merely of the cadaver by the usual methods, but of the surroundings, both on the occasion of the first discovery and subsequently Such investigations, he contended, should be made by skilled medical observers and, while the first results would be found of value in the performance of the subsequent post mortems, data obtained at such post mortems would indicate the lines on which later examinations of the site of the alleged or suspected crime should be conducted —In the course of the discussion that followed Lord Justice Atkin emphasised the value of the work of the Medico Legal Society and expressed the desire that some means might be found to bring directly before coroners, chief constables, and others such points as those so ably expounded by Dr Spilsbury His lordship also drew attention to the difficulties attending the forensic investigation of crimes of violence which fell short of murder or manslaughter —Sir William Collins, Earl Russell, Major Haden Guest, Dr W H Willcox, Mr A B Watson, Dr J Maughan also spoke, and Dr Spilsbury replied

Reviews and Notices of Books.

AN INTRODUCTION TO THE STUDY OF CYTOLOGY.

By L. DONCASTER, Sc.D., F.R.S., Derby Professor of Zoology in the University of Liverpool. Cambridge University Press. 1920. Pp. 280. 21*s*.

THIS is not a text-book in the ordinary acceptation of the term. It aims at giving an account of the more important facts of animal cytology, but its chief purpose is to interest the student in the subject by pointing out some of the ways in which cytological investigation is related to the great fundamental problems that lie at the root of all biological research. The plan is based on courses of lectures given by the writer during six years at Cambridge. The scope will be indicated by a brief statement of the chief subjects dealt with. Without going fully into cell-physiology, the author deals with the cell, its organs, the nucleus, mitochondria and Golgi apparatus, with cell-division, amitotic and mitotic chromosomes, achromatic spindle, the centrosome and its origin, cytoplasmic division, and multipolar spindles (pp. 1–58).

While the chromosomes have attracted much attention in consequence of the probability that in them is to be found the solution of some of the fundamental problems of heredity, yet the nature and mechanism of the achromatic spindle offers problems hardly less fascinating, and perhaps equally far-reaching as regards the nature of the vital process. Having dealt with cell-division in ordinary body cells, the author proceeds to study the maturation of the germ cells, spermatogenesis, maturation of the egg and the meiotic phase, the cytoplasmic structures in spermatogenesis and oögenesis, fertilisation and segmentation (pp. 59–124). In all organisms in which sexual reproduction occurs the doubling of the number of chromosomes in the zygote is avoided by the process known as "reduction of the chromosomes"—a process which is fully explained. In the development of the egg the process is exactly analogous to that in the spermatozoon, allowance being made for the minuteness of the one and the relatively large inert often yolk-laden egg. The details of fertilisation and segmentation are set forth in a very attractive form and the probable forces at work discussed. This leads on to parthenogenesis—a mode of reproduction which occurs in nature under a number of different circumstances and most frequently alternating more or less regularly with bisexual reproduction. Artificial parthenogenesis (pp. 140-151) has recently attracted much attention, and has been more particularly studied in sea-urchins' eggs, by the action of various mineral salts and other organic acids.

The cytological basis of sex-determination is next considered, the hymenoptera, perhaps, are the best-known examples. As to germ-cell determinants, all the evidence points strongly to the conclusion that in many animals sex is determined by, or at least is correlated with, the presence or absence of a particular chromosome in the fertilised egg, or among parthenogenic animals in the egg after maturation. The theory of the individuality of the chromosomes is next exemplified and discussed (pp. 172–205). A very interesting chapter is the one on the mechanism of hereditary transmission, with full discussion from Weismann's famous theory of the germ plasm (1885) onwards. "If the facts of heredity were not so familiar they would be regarded as the most wonderful in nature, and it is not surprising that one of the chief aims of cytologists has been to find some explanation of this mechanism," and this the author proceeds to do, discussing the rôle of the nucleus, chromosome, the possible relation between Mendelian segregation and chromosome behaviour, specific chromosomes and sex-determination, and cytoplasm in development and heredity (pp. 206–265). There are 24 plates, 31 text-figures, and a useful bibliography running to 10 pages.

In this monograph zoology and physiology go hand-in-hand. The author has given a most suggestive as well as comprehensive survey and critical exposition of the newer facts and aims of cytology, but even without the great array of facts a real comparative cytology can hardly be said to exist, so vast is the field still unexplored. However, the author has made a worthy contribution to a fascinating and progressive subject.

MODERN SPIRITISM.

By A. T. SCHOFIELD, M.D. London: J. and A. Churchill. 1920. Pp. 260. 3*s*. 6*d*.

SPIRITISM, says Dr. Schofield, may be regarded either as a religion or as a science. As a religion its adherents "are now numbered by millions," the most prominent of whom, in this country, are Sir A. Conan Doyle and Sir Oliver Lodge. As a science the phenomena with which it deals may be classified as "physical" (levitation, astral emanations, materialisation of spirits, &c.), and "psychical" (e.g., communion with the dead, automatic writing, cross-correspondence, &c.). Dr. Schofield's purpose is to examine critically the claims of modern Spiritism, and to show its incompatibility with Christianity. In this endeavour he may be said to have failed conspicuously. The main substance of his book appears to have been gleaned from newspaper cuttings and extracts from books thrown together in utterly illogical order. As an example, Eusapia Palladino's conviction of fraud is laid bare, but two pages later, following a paragraph which is headed "proved facts," he describes an investigation of Eusapia at Naples, at which "three clever sceptics" (with names mis-spelt) "were absolutely convinced of the genuineness of the physical phenomena shown."

Dr. Schofield believes in demoniac possession and says that such possession by the devil, "if proved, turns the whole position of those Spiritists who declare the next world is denizened only by the disembodied spirits of the dead." He classifies cases of multiple personality among the insane, and says that they "are not very rare in asylums." In physics the author is on no safer ground. He writes that "vibrations from 16 to 36,000 per second are known to us as sounds. From 36,000 to 1,000,000,000 (a pretty large range) they are imperceptible. Above 1,000,000,000 they [presumably aerial vibrations !] are perceived as electricity. From 2,000,000,000 to 250 billions (!) (a still greater jump) the vibrations are again imperceptible. From 250 billions to 1000 billions they are again seen as light and colour, from infra-red to ultra-violet." And so on, adding an ingenuous footnote that these numbers are "wholly inconceivable."

Other examples of the same kind of imperfect knowledge are not difficult to find. It is surely high time that the medical student received adequate training in the principles of psychology and physics.

HENRY QUIN, M.D. (1718–1791).

By T. PERCY C. KIRKPATRICK, M.D., M.R.I.A., Fellow and Registrar of the Royal College of Physicians of Ireland. Dublin: At the University Press. 1919. Pp. 66. 10*s*. 6*d*.

Dr. Henry Quin is one of those of whom Shakespeare said,

> "for if our virtues
> Did not go forth of us, 'twere all alike
> As if we had them not."

For though he was a prominent physician in his day and a figure in Dublin society, yet, says Dr. Kirkpatrick, "he was soon forgotten after his death, and there is not, as far as we know, any record of his life among the published biographies of distinguished Irishmen." In August, 1918, a bust of Quin was presented to the Royal College of Physicians of Ireland by Dr. Alexander Morison, and this presentation moved Dr. Kirkpatrick to pay "a well-merited if tardy tribute to one to whom Ireland owes much." One of Quin's relatives was James Quin, the actor, who died in 1766.

Dr. Kirkpatrick found some difficulty in tracing the genealogy of Henry Quin; *his father was undoubtedly* Thomas Quin, a well-known Dublin apothecary, and his grandfather was presumably another Thomas Quin, a bricklayer of Castleknock Henry Quin graduated a Bachelor of Arts at Trinity College, Dublin, in 1737, being then 19 or 20 years of age He then proceeded to the study of medicine, where is not known, but in 1743 he was admitted Bachelor of Medicine of the University of Dublin After his graduation in medicine he presumably went abroad for study, as in 1749 he reappeared in Dublin as a Doctor of Medicine of Padua and in the same year he was elected King's Professor of the Practice of Physic in the Medical School of Trinity College In the following year he was admitted Doctor of Medicine of the University of Dublin, and in 1754 a Fellow of the College of Physicians His appointment as King's Professor very soon put him in the way of obtaining a fashionable practice, for in 1750 he was sent for by Dr Patrick Delany, Dean of Down, to attend his wife, the celebrated Mrs Delany the friend of Swift, and the introducer of Fanny Burney to Court The wheels of his life ran smoothly, in 1753 he married Miss Monck whose brother had married a daughter of the first Duke of Portland She brought him £5000 and an entry into the highest circles of Dublin society, where he shone not only by his "great erudition,' but also by being an accomplished performer on the harpsichord He was, in addition, a virtuoso in the matter of cameos, and attained such skill in the art of making artificial cameos and intaglios with glass paste "as even to deceive the proprietor of a fine original He was the patron and teacher of the well known James Tassie, who produced many and excellent copies of cameos, and he befriended and helped to train William Mossop, the medallist Of Quin's medical work but little is known he was seven times President of the College of Physicians, and he seems to have noted the presence of tubercles and inflammatory symptoms in two cases of acute meningitis, though, of course, he had no idea as to the nature of the tubercles He died in 1791, leaving behind him a considerable fortune

Of his three sons, Charles William, the second was also a member of the medical profession, and, like his father, was interested in apoplexia hydrocephalica—i e, acute meningitis He wrote a book entitled, "A Treatise on Dropsy of the Brain published in 1790, wherein he shows that he had grasped the difference between chronic hydrocephalus and meningitis He died in 1818 His younger brother, Henry George, apparently had no profession, but was able to devote his time to art and foreign travel He left a diary behind him, which came into Dr Kirkpatrick's possession and from which he gives some interesting extracts He obtained the post of Second Chamberlain in the Court of the Exchequer, which carried with it the not over generous salary of £52 3s 4d per annum He collected a small but valuable library, which he bequeathed to Trinity College, one of the books being a fine copy of Virgil, printed in 1470 Dr Kirkpatrick's little book is a pleasant record of an interesting society, although we cannot agree in his estimate of the Quin family as remarkable Rather we should say they were intelligent people, who had an easy time and were able to gratify their tastes

JOURNALS

Journal of Anatomy Vol LIV, Part I October, 1919 Cambridge University Press Pp 1–100 7s 6d net —In the first and longest paper in this number Professor Arthur Thomson, writing on the ripe Graafian follicle, makes an important contribution to the study of the normal human structure Owing to the plenitude of detail the paper does not easily admit of abstraction, but will repay reading in full Professor Thomson adopts the view that the discus may be placed on any part of the circumference of the follicle, against the well known doctrine of Nagel and his followers He also gives reasons for supposing that the bodies which were described among the follicular cells by Call and Exner some 30 years ago are in reality groups of follicular cells which are undergoing changes that ultimately lead to the appearance of the liquor folliculi, in this, of course he supports the opinions previously advanced by Nagel Winiwarter has described plain muscle cells in the outer theca in the cat, and Professor Thomson claims that they are also present in the human follicular wall An interesting experiment by Professor J A Gunn is incidentally introduced in this connexion, demonstrating (we believe for the first time) the presence of the contractile fibres in the ovary —Professor F Wood Jones, in describing voluntary muscular movements in cases of nerve lesion, has had the advantage of having seen the actual condition of the nerve in every case and of having checked the findings by electrical test He has produced a collection of facts of great practical interest, and some of the actions he demonstrates will probably be new to his readers It may be pointed out that in some things he flogs a horse which was never alive, for much of the erroneous teaching he deplores had no support among anatomists —Professor F G Parsons and Mrs Lucas Keene deal with the sexual differences in the English skull as seen in the classes from which medical students are drawn While the facial index is the same a definite distinction comes in the length, height, and interzygomatic width, and the most striking difference perhaps, is found in the width of the palate —Professor T B Johnston gives a detailed account of the ileo cæcal region in *Callicebus personatus*, and goes into a general consideration of the morphology of the mammalian cæcum, which he considers to have been primitively an asymmetrical outpouching —Dr F H Edgeworth dealing with the laryngeal muscles in Sauropsida, derives them from a constrictor œsophagei Fuller description of the obliquely cut sections, with one or two reconstructions, would greatly aid comparison between the sauropsidan and mammalian conditions —Dr A Blackhall Morison describes a heart with persistent foramen primum, of clinical interest in that it was found in a woman of 43 the mother of five children —The number closes with a memorial notice of the late Professor Alexander Macalister, from the pen of Professor E Barclay Smith, who was associated with him for many years The notice is accompanied by an excellent portrait

Journal of Hygiene Vol XVIII, No 4 February, 1920 Edited by Professor G H F NUTTALL, F R S —The principal contributions to the February issue of this journal are two by Dr E C Hort one on the cultivation of aerobic bacteria and one on the reproduction of aerobic bacteria The remaining papers cover a wide field of scientific activity, as will be seen in the following short notices of each communication The first paper by Dr Hort dealing with the technique of the isolation of single bacteria is a useful critical account of the numerous methods which have been advocated Most of the methods described suffer from a number of defects, the chief being due to optical difficulties Dr Hort favours the perforated plate method owing to its comparative simplicity, rapidity, and inexpensiveness How far these methods are laboratory "tricks and of no real value is not fully discussed Dr Hort's principal paper deals with the reproduction of aerobic bacteria It is the continuation of a series of papers dealing with the same subject which have been published from time to time since 1916 The main thesis of the contribution is that the simple bacteria do not divide always or only by simple fission, but also by more complicated processes —The *Diets of Labouring Class Families during* the Course of the War, by Margaret Ferguson, M A An account is given of an inquiry as to the diets of five families during 1917 and 1918 The children of three of the families were below the average in weight and height, due probably to an insufficient supply of food In a fourth family it was found that children who had suffered from low diet as shown by weight and height, recovered and gained normal development when supplies became plentiful The problem is shown to be economic Only one of the families studied "could afford even the freedom of choice afforded by the rationing scheme —A Polyvalent Vaccine in the Treatment of Bacillary Dysentery in East Africa by W H Kauntze The author describes in detail the symptoms and physical signs of bacillary dysentery in the African native and the appropriate treatment. Vaccine therapy in his experience is valuable. His method of killing the organism in the preparation of the vaccine was by means of carbolic acid.—Cats and Human Diphtheria, by W. G. Savage, M.D. It has been commonly believed since the work of Klein (1888) and others that cats may suffer from a naturally acquired disease caused by the diphtheria bacillus, and that, further, they may act as carriers of this organism. This belief is rudely shaken by Dr. Savage's work. He shows that in the throat of normal cats there is found an organism morphologically resembling *B. diphtheriæ*, but differing from it in certain respects in culture, and in being non-pathogenic to guinea-pigs. Further, the examination of cats which have been in close association with cases of human diphtheria failed to reveal the diphtheria bacillus. Experimentally, the injection of cultures of *B. diphtheriæ* under the skin of kittens produced illness and death, with pathological lesions characteristic of diphtheria. But the feeding of kittens with cultures of the bacillus produced no effects, and attempts to infect the animals by swabbing the nose and throat with massive doses were uniformly negative, the organisms so introduced disappearing within 24 hours. It is apparently safe to conclude that cats are not associated in the spread of diphtheria.—A Note on "Defence Rupture" and the Action of Electrolytes, by W. Cramer and W. E. Gye. A reply, in the form of a description of experiments, to criticisms by C. Shearer in the previous number of the *Journal of Hygiene*.—The Contamination of Oysters, by A. T. Nankivell, M.D., and Sergeant J. M. Stanley, A.A.M.C. In this paper the author shows that the contamination of Poole Harbour comes in with the flood tide from the open sea.

The Journal of the Royal Naval Medical Service for January (John Bale, Sons, and Danielsson, Ltd. 6*s.*) has commenced the publication of papers on the Naval Medical History of the War; they will continue through the next two years and, judged by the papers that appear, will be of great importance to the medical historian. Temporary Surgeon-Lieutenant W. M. Fairlie gives an account of poisoning by nitrous gases, chiefly the result of the burning of cordite. They act in very high dilution with a period of latency, which is usually about 12 hours; early symptoms of irritation to the air-passages appear, later acute pulmonary œdema going on to frothy sputum and cyanosis, followed by acute emphysema and cardiac distension. As to treatment, emetics and atropine were of use early; later, bleeding up to 12 ounces. The viscidity of the blood observed suggests that intravenous saline might have been of use, as in cholera.—Surgeon-Commander R. C. Munday, has a paper on Ventilation and Heating of Ships, much of which has already appeared in print in Pryor's "Naval Hygiene," reviewed by us on Nov. 8th, 1919. A tabular view of the efficiency of each fan mentioned would have been useful. The heating of ships appears to be secured by putting heaters into the delivery trunks for large spaces, while in small compartments like cabins air is supplied cold and heating is secured by radiators.—Commander P. T. Sutcliffe tells how the official diets were varied through the war in consequence of the limitation of essential food-supplies at various periods.—Surgeon-Lieutenant (D.) G. E. Wood, R.N.V.R., has a very good paper on Dentistry, showing how small was the establishment of dentists when war began, and how circumstances and experience proved the need of a larger staff, and how wisely the increase was made. At first there were 23 civilian dental surgeons, all on shore; they were next sent to naval hospital ships with the Fleet; then those serving afloat were given commissions in March, 1915; then in 1918 all ashore as well as afloat were given commissions, and at the armistice there were 83 in service, many in battleships and cruisers. He mentions a case in which the patient had had three teeth knocked out, but they were treated and replaced, and became fixed quite satisfactorily.—Temporary Surgeon-Lieutenant T. Beaton gives a very valuable paper on the mental cases, which is to be continued.—The Editor expresses in Latin his regret that he is leaving—a regret all will share.

In the *Annales de Dermatologie et de Syphiligraphie* (VIe Serie, Tome 1) appears an original article by Cordier and Dechaume on Syphilitic Diabetes and Glycosuria of the Tertiary Period. The authors describe the various clinical types of diabetes that may be attributed to syphilis. In the secondary stage a mild and transitory glycosuria is occasionally observed. In the tertiary stage various forms appear: (1) a form associated with some cerebral lesion; (2) a form associated with lesions of the pancreas; (3) a type which is apparently independent of any cerebral or pancreatic lesion. In addition to the above, diabetes has been found in association with parasyphilis and hereditary syphilis. The characteristics of the different forms of diabetes are given, together with a very complete summary of previous observations on the subject. Various conditions should be satisfied before a case of diabetes is put down to syphilis: (1) the appearance of the diabetes should be subsequent to the infection with syphilis; (2) it should appear at the same time as other syphilitic manifestations; (3) antisyphilitic treatment should cure the diabetes as well as the other lesions; (4) antidiabetic treatment should be without effect. These conditions are not absolute and vary in importance as indications of the true nature of the diabetes. Indeed, according to Troller, the fourth condition is valueless, since all varieties of diabetes are to some extent improved by general treatment. The results of treatment in cases of diabetes due to syphilis are very encouraging. Large doses of arsenical compounds should, however, be avoided. The authors suggest that syphilis is the probable explanation of those curious cases of diabetes occurring in husband and wife, an association which has given rise to a hypothesis of a diabetes that is infectious in origin. In a series of 516 diabetics collected by Senator the husband or wife, as the case may be, developed diabetes subsequently in 18 cases (3·5 per cent.). No particular attention was paid to a history of syphilis, and it is possible that a careful investigation along such lines would have revealed the explanation of this conjugal diabetes. At any rate, the possibility of syphilis should always be kept in mind when dealing with such cases.

Bulletino delle Scienze Mediche. 1920. XCI. Bologna: Piazza Galvani.—This journal, edited by Professor Ercole Giacomini, enters this year the eighth volume of the ninth series. It was founded in 1829, and constitutes the official report of the Medico-Chirurgical Society of Bologna, with Professor Guido Vernoni and Professor Sherardo Forni as editorial secretaries. In addition to the report of the society's meetings in 1919, the January number contains two original communications. The first is by Professor Vernoni on the dialysable and non-dialysable alkaline content of normal and antitetanic horse serum. The alkalinity of the blood plays an important, although imperfectly understood, part in the production of "shock," as shown by Lewis, Fullerton, Moore, and others in this country, and Professor Vernoni has conducted numerous researches in this respect on the serum of normal horses and of those vaccinated against tetanus toxin. In the latter he found that the total alkalinity—i.e., both proteid and dialysable—was increased, and, moreover, was united to the proteins in a different manner to that of normal serum. The second paper is by Dr. Frank Fama on the colour reactions in protozoal blood infections to eosin. After numerous experiments he has developed a technique which seems to give highly satisfactory results. Its chief point of interest lies in the fact that the stain and the mordant are in two separate solutions. The former is a solution of 5 per cent. bromo-ammoniate of eosin and 20 per cent. methylene-blue in anhydrous methyl alcohol, the latter a solution of triphenylmethane. These two are mixed, just before use, in proportion of about 3 to 1, and the slide with the blood-smear is prepared in the usual way. The result is that the leucocytic and protozoic chromatin are coloured violet, the eosinophile granules red, the basophiles blue, and the mononuclear protoplasm pale blue. The preparations are not decolourised by xylol balsam and are permanent.

THE LANCET.

LONDON: SATURDAY, APRIL 3, 1920.

Medical Benefit in 1920.

THE Medical Benefit Regulations in their final form for the year 1920 are issued just in time to become operative on April 1st. The new features include a much larger share in the administration of the service by the professional committees. The Allocation Subcommittee now set up is a composite body equally representative of the Insurance and the Panel Committees, with a chairman chosen from the neutral members of the former. This joint subcommittee will have supervision and control over the lists of practitioners. It will frame an allocation scheme to provide for the distribution of insured persons in the area, and for the assignment of persons who have not chosen a practitioner of their own accord. Under this scheme provision must be made for the giving of emergency treatment, and only great tact and skill can make this emergency provision a success. The same subcommittee will have the duty of limiting the lists of practitioners in certain respects, and in the course of its work will presumably have to review the efficiency of practitioners working in difficult areas. The scheme as it stands is largely experimental, and may have to be revised in many areas after a year's experience of its working.

The method of distributing the practitioners' fund in any area is laid down by a distribution scheme, prepared jointly by the Insurance Committees and the Panel Committees, under which the methods of payment of the practitioners are decided, and provision is made for special payments for anæsthetics and emergency treatment, the accounts in every case being submitted for scrutiny to the Panel Committee. Payment in respect of temporary residents now takes the form of a special capitation fee, and provision is made for the payment for drugs and appliances administered by practitioners. Other changes affect the procedure of the Medical Service Subcommittee. Its term of office and method of taking evidence cannot now be decided without consultation with the local Medical and Panel Committee, whose secretary is summoned to the meeting. In one particular the action which may be taken by the Insurance Committee has been extended: on substantiation of complaint against a practitioner his practice may be reviewed with a view to the reduction of his list beyond the limits ruling in the area. A new feature in the procedure of appeal is the proviso that the Minister of Health shall, if so directed by the court hearing the complaint, state in the form of a special case, for the opinion of the court, any question of law arising in the course of the appeal, and may state his decision as to the whole or any part thereof in the form of a special case. This is a wise innovation, and should give a sense of increased security to practitioners.

The terms of service are set out in the first part of the first schedule. They include the new arrangements for the transfer of practices on retirement or death. Over this regulation there has been much bitter controversy, and the Ministry has remained unmoved by the argument that the goodwill of panel practices would be seriously affected thereby. The object of the new regulation is clearly to put the insurance practice on the same basis as the private practice, in negotiating either of which the practitioner can only claim to sell the introduction to a certain group of prospective patients. The safeguards which have been devised will enable the Allocation Subcommittee to protect the interests of panel practitioners generally, and especially the widow and friends in the case of a death vacancy. One of the clauses in this part sets out the obligations of the practitioner with regard to deputies, assistants, and partners, and in the case of a principal and assistant gives the insured person the right to require the personal services of the principal. These are the main points in which the regulations alter the existing arrangements of panel practice. Taken as a whole they are designed to improve the service, to define points which have hitherto been doubtful, and to make clear in the minds of the practitioner the obligation he undertakes in his agreement with the Insurance Committee.

◆

Anæsthetics in Labour.

THE ideal anæsthetic during the process of labour should keep the patient entirely free from pain, should have no effect in delaying the progress of the labour, and should produce no deleterious effects on either mother or child. Are we at present capable of exercising such an ideal control by any of the anæsthetic agents at our disposal? It is quite true that by a sufficiently liberal use of chloroform we can render the process painless from first to last. We do so, however, only at the cost of a longer labour. If chloroform is so given that no pain at all is felt, it will be given to a degree which will, in the second stage, abolish the voluntary bearing-down efforts of the patient, and will in this way inevitably delay the labour, even if this delay is not further brought about by the action of the anæsthetic in weakening the uterine contractions. Similarly, "twilight sleep," when really effective as a safeguard against pain, inevitably prolongs labour, and in addition there is undoubted risk to the baby. The same arguments apply to the free exhibition of ether in labour. How does the case stand as regards nitrous oxide, the other usually available anæsthetic? At first sight it would appear that this agent, by which an anæsthesia can be produced rapidly, and as transiently as the labour-pain it is intended to assuage, and which will have no toxic effect, should be the ideal for our purpose. As regards the less painful stages of labour indeed we may so regard it. The drawback to nitrous oxide in this connexion is that it will not really defeat the pain at the most painful stage, when the head is passing over the perineum, and thus fails us just at that time when we most require its effective help. Some practitioners, indeed, scarcely use an anæsthetic at all until this critical stage is reached. For them nitrous oxide will have little attraction. Moreover, one of the advantages claimed for it, that it does not diminish the resistance of the patient to infection, is not peculiar to nitrous oxide.

Nitrous oxide is more largely employed in obstetrics in the United States than in this country, being generally employed in the second stage of labour. In the *New York Medical Record* a recent paper by Dr. RAYMOND C. COBURN recommends this anæsthetic in a more general way, preferring it to either ether or chloroform throughout the entire period of parturition, excepting at the final stage, when, he suggests, ether can be added to the nitrous oxide or ether alone can be administered to bring about anæsthesia. His objections to the use of ether or chloroform are much those that we have already set out—that they delay the progress of labour and decrease the patient's powers of resistance, if given in sufficient amounts to relieve the patient of pain, while he rightly points out that it is the fleeting character of the anæsthetic properties of nitrous oxide that make it especially suitable as an analgesic for obstetrical conditions. But Dr. COBURN overlooks the fact, we think, that other anæsthetics, if used only to produce intermittent analgesic states, will have no effect in diminishing the resistance of the patient. If such effect is produced it will only be when the anæsthetic is pushed to the surgical degree of narcosis, in order to defeat pain, during the passage of the head over the perineum. That is to say, if they are harmful as regards the patient's resistance it is only because they are used for an end which nitrous oxide is unable to attain. Actually we doubt whether the amount of weakening of resistance occasioned by the anæsthetic is ever formidable if the latter is skilfully employed.

Chloroform in very dilute vapour can be used during labour over long periods of time without damaging the patient in any way, and without diminishing the uterine contractions. It must be used, however, with skill, with discretion, and with unremitting attention. It must be used in a manner which can hardly be expected if the anæsthetic is simply handed over to a nurse acting more or less under the supervision of the accoucheur. Indeed, one of the chief arguments in favour of the employment of nitrous oxide appears to us to be that this would necessitate the administration of the anæsthetic by a medical man. Certainly, if the conduct of a labour case is to be such as was outlined in our columns recently by Dr. VICTOR BONNEY[1]—that is to say, on strictly surgical lines—then the presence of an anæsthetist will be required more often than has hitherto been the case. Nor can we doubt that this will be all to the benefit of the patient.

◆

Clean Milk.

CLEAN milk is coming. The dirty byre and the dirty cow have notice to go. The cow must be groomed for more important reasons than the horse. Light, ventilation, drainage, with an ample supply of water, must rule in the dairy farm, and dairy farmers are taking an intelligent view of the situation, thanks to the representations of medical science and the insistent work of public-spirited men, landowners and others. As is well known, milk in the past has shown an appalling bacteriology, the inevitable result of insanitary conditions amongst the herds. If a water-supply should yield a count of bacteria infinitely lower than that of average milk that supply would be condemned. Experience has often shown that it requires no scientific refinements to disclose the gross impurities of milk when mere filtration or sedimentation reveals a deposit of dung. Such filthy disregard of cleanly procedure promises to be a thing of the past, but even reform up to this point has taken a long time to materialise. But the Government and the people are now awake to the errors of the past and the possibilities of the future, and it is to be hoped that the movement now well begun in favour of producing clean, scientifically clean, milk will become universal.

It is interesting to recall that the propaganda as regards certified milk, now obtainable under a system of licences issued by the Ministry of Health, is no new idea. As far back as 1891 a system of certified milk-supply was suggested by Dr. HENRY L. COIT, of Newark, New Jersey. The movement soon gained the support of the medical profession in America, and a Medical Milk Commission was formed which, amongst other things, required that the dairy farmer, under a specific contract, should agree to conduct his business on well-recognised hygienic lines from beginning to end. When the commission was satisfied that these conditions were complied with, including both regular inspection of the farm and herd and chemical and bacteriological control of the milk, the producer was entitled to label the milk "certified milk." In 1909 an Act was approved providing for the incorporation of medical milk commissions and the certification of milk produced under its provision. In 1912 the American Association of Medical Milk Commissions issued and adopted methods and standards for the production and distribution of certified milk. The details of this scheme form the basis of the system now sanctioned by the Ministry of Health in this country. Licences to supply certified milk are issued when the wholesale or retail distributer complies with conditions satisfying a representative of the Ministry of Health or of specially empowered local authorities. The herd from which the milk is obtained must contain no cow or heifer in milk or in calf, or other bovine animal kept in contact with the herd, which has not passed specified tuberculin tests. Further conditions are that—

---

[1] THE LANCET, 1919, i., 775.

(1) The milk must be cooled and bottled immediately after production for delivery to the consumer in bottles which have previously been sterilised by steam on the premises where the milk is produced.

(2) Every bottle must be covered with a suitable outer cap overlapping the lip of the bottle, and this cap must bear the name and address of the producer, or of the farm where it is produced, the day of production, and the words "Grade A (Certified) Milk."

(3) The milk on examination at any time before delivery to the consumer must not contain *B. coli* in 1/10 c.cm. (in each of two tubes) or more than 30.000 bacteria per c.cm.

(4) The milk must not be delivered to the consumer as Grade A (Certified) Milk more than two days after the day of production.

It has been amply demonstrated that the conditions imposed are readily workable at the dairy farm, and that the employees appreciate quickly why these hygienic steps are taken: they enter wholeheartedly into the spirit of a policy of clean milk the moment they understand the crudeness and dangers of coarse and antiquated methods of drawing milk from the cow for public consumption.

Hygienic methods of milk production will, of course, inevitably raise the price of milk to the consumer, owing to the extra precautions taken, and the work involved to supply a guaranteed pure and clean article. This advance in price amounts, after all, to the cost of security, or an insurance against risks to health, particularly in the case of young children and invalids. The thing can be done, as evidenced in the admirable model dairy farms of Mr. WILFRED BUCKLEY, Director of Milk Supplies, Ministry of Food, and of Lord ELVEDEN, and Lord ASTOR. This pioneer work is of the utmost importance to the community, and there is distinct hope of the movement spreading. The members of our profession will appreciate this promise of progress, which they have been insistent in demanding for many long years.

THE King Edward VII. Hospital, Cardiff, which recently appealed for £150,000, has already received subscriptions amounting to £110,000. The full sum wanted will, it is hoped, soon be obtained.

UNIVERSITY OF WALES.—A representative deputation from the University of Wales was recently received by the Prime Minister to consider the recommendations of the Royal Commission. Agreement was arrived at as to the lines of a new charter. Under this local authorities may contribute a penny rate to the University, and the Treasury will make an equal contribution. Further, in the case of any private benefaction the Treasury will contribute pound for pound. The exact position of the school of medicine was determined; it is to remain, as at present, an integral part of the University College of South Wales and Monmouthshire situated at Cardiff. The full development of the school has been awaiting decision on these matters, and is expected now to go forward rapidly.

Annotations.

"Ne quid nimis."

VILLAGE SETTLEMENTS FOR THE TUBERCULOUS.

Dr. Addison stated in the House of Commons last week that, while institutional treatment for insured persons suffering from tuberculosis is already being provided in most areas by the public health authorities, by arrangement with the Insurance Committees, imminent legislation will lay this treatment as an actual duty upon the authorities. This will hardly cover the establishment of village settlements for the treatment of tuberculous ex-soldiers, which was one of the pressing recommendations of the Inter-departmental Committee on Tuberculosis. The deputy chairman of this Committee, Sir C. A. Montague Barlow, M.P., recently headed a deputation to Dr. Addison to lay before him the case for the establishment of such settlements. Sanatorium treatment for tuberculosis, even where accompanied by training in a suitable occupation, has, it was stated, been found inadequate as a means of combating the disease. Many patients returning from a sanatorium to their homes and former occupations are unable permanently to earn a living or maintain their health. The interest both of the patients and of the community, so the argument ran, requires that patients should pass through a three-fold course, first of sanatorium treatment, secondly of training, and thirdly of permanent settlement in suitable surroundings. The suggested village settlement is to be a natural development of the sanatorium and training colony. On completion of his course of treatment and training the ex-Service man should take up his permanent residence in a settlement where, still in close touch with the sanatorium, he could have his family with him and work under conditions enabling him to maintain his health. His earnings would require to be supplemented, but the community would be the gainer in the transaction by the prevention of the spread of infection, and the fact that the tuberculous patient would remain a productive worker. An article, in another part of our present issue, by Mr. P. C. Varrier-Jones and Sir G. Sims Woodhead, both of them members of the deputation, sets out the claim of poultry-farming to consideration as a productive industry for consumptives. Dr. Addison, while assuring the deputation of his goodwill, did not conceal the difficulties which were to be overcome. The success of a village settlement depended, he thought, more upon the personality of the man in charge than upon the material provision made. As regards finance, the provision of ten settlements for not less than 200 patients each, as proposed by the Inter-departmental Committee, would, he considered, cost much more than the estimated sum of £1,000,000. He could not consider the case of the ex-soldier apart from that of the civilian population, which had no pensions to supplement their earnings. Dr. Addison concluded by intimating the selection of Dr. Nathan Raw and Mr. Varrier-Jones, in conjunction with a medical officer of the Ministry, to make local investigations with a view to the choice of site for the projected settlements. The choice may be no easy matter, for in addition to favourable climatic conditions, local industries and local markets will both have to be considered. No site chosen can escape criticism from some point of view.

OUTDOOR MEDICAL OFFICERS OF THE MINISTRY OF HEALTH.

WE call attention again to the proposed appointments on the outdoor staff of the Ministry of Health set out in our advertising columns. They refer to 18 medical officers for England and 3 for Wales. A committee has been set up to consider applications for these appointments and to make recommendations to Dr. Addison. This committee includes medical men of high standing from different parts of the country, one of whom is to be its chairman, with a nominee of the Civil Service Commissioners and two representatives of the Ministry of Health. The personnel of the committee will not be announced until after it has made its recommendations. The decision to make the appointments is the result of prolonged thought and negotiation. It embodies the conception of medical referees set forth in the well-known circular (M.25) of the British Medical Association, and the selected men will represent the referee-consultants for whom provision was made in the summer of 1914, when the scheme was held over on account of the war. These whole-time officers are to have functions which are primarily administrative, but at first their duties may be largely clinical, because they are to take the places as official referees of the consultants who have been acting in this capacity under private arrangements with the Approved Societies. They are to act as expert advisers to the authority responsible for the clinical service, and will probably have supervisory powers in the administration of the service. These officers are already referred to in the new Medical Benefit Regulations as the medical officers to whom reports are to be furnished, and with whom consultations will be arranged on any patient in respect of whom a practitioner seeks special advice. The appointments are of the utmost importance to the medical profession as the first step in the further organisation of the Medical Service. We may regard them as forming a link not only with the local health authorities when these should finally be determined, but with the hospital and specialist services which are to be provided in the near future.

ACUTE CHOLECYSTITIS IN CHILDREN AS A COMPLICATION OF TYPHOID FEVER.

THE constant infection of the gall-bladder at some stage of typhoid fever, and the important rôle of the typhoid bacillus in the production of cholecystitis and gall-stones, have been recognised for some years, but the cases of empyema of the gall-bladder or acute cholecystitis that require surgical treatment or prove fatal are few. In children [illegible]ute cholecystitis of any kind is rare. In the [illegible]ns *Hopkins Hospital Bulletin* for January Mr. M. R. Reid and Mr. J. C. Montgomery have reported the following case:—

A girl, aged 8 years, was admitted on Dec. 20th, 1918. Abdominal symptoms had begun a week before after an illness of eight weeks, marked by fever, delirium, headache, and diarrhœa. On admission she was emaciated and complained of pain in the abdomen and a large abdominal mass. The temperature was 98·8° F. and the pulse 100. The abdomen was distended, especially on the right disc, and the venules in the skin were prominent. A large smooth mass, extending from the ribs to the level of the anterior iliac spine on the right side, could be seen and felt. The temperature varied during three days from 99° and 104°. Various diagnoses were suggested—retroperitoneal sarcoma, sarcoma of the liver, abdominal abscess, appendix abscess. An affection of the gall-bladder was discussed, but thought unlikely on account of the huge size of the mass. On Dec. 23rd an operation was performed. A distended gall-bladder containing almost a litre of pus was found. It was removed, and after convalescence the patient rapidly gained weight. Cultures from the gall-bladder yielded the typhoid bacillus in pure culture. A week after the operation the urine also yielded a culture of the typhoid bacillus. The gall-bladder showed typical acute hæmorrhagic cholecystitis with necrotic areas.

Mr. Reid and Mr. Montgomery have been able to find recorded only 17 other cases of typhoid cholecystitis in children, although their search goes back to 1835. In the 18 cases the patients were children under the age of 15, who either died from, or were operated on for, cholecystitis complicating typhoid fever. In 11 cases acute cholecystitis did not develop until eight months after recovery from the disease; in the others the complication occurred during the illness. Eight of the patients died without operation, and all of these cases were reported before 1893, since when 10 cases have been treated surgically, with one death. The authors insist on the importance of distinguishing between gall-bladder complications of typhoid fever that do and do not require surgical treatment. Slight pain and tenderness in the region of the gall-bladder, with slight spasticity of the rectus, are not very unusual in typhoid fever, and the vast majority of the patients recover. But immediate operation is indicated in acute suppurative cholecystitis, as rupture of the gall-bladder may occur. Cholecystectomy appears to be the best treatment.

PSYCHOLOGY AND REALITY.

IN these days psychology is taking on a new aspect in that the science is, as the more academic followers of it may think, demeaning itself by the recognition of utilitarian purposes, and the conception of its practical side is being extended to embrace problems concerning such varied matters as the influence of fatigue, systems of memory-training, advertising, the investigation of crime, and the laying of bricks. Quite an extensive literature is growing up round the application of psychological methods to industry, and for a long period we, being perhaps lacking in the kindness of heart and simple faith which characterise some psychologists, have watched the developments which are taking place with curiosity as to the stage at which the altruistic tone would disappear. That the working man should lend himself to a scheme of examination into his capacity which might mean his being displaced by somebody who could do his job better, or which might provide a logical basis for paying him less is surely unlikely; but hitherto there has been surprisingly little recognition of this fact in the various treatises which deal with the most profitable ways of running the industrial machine. To the *British Journal of Psychology* for March, 1920, Mrs. S. S. Brierley[1] contributes a paper which presents this aspect of the matter. "The attention of psychologists," we are told, "has recently been drawn to the widespread opposition to the introduction of psychological methods into industry, existing among organised labour." Even among educated workers, as Mrs. Brierley shows, there is opposition to the principles of "scientific management," and whether this opposition is merely selfish, or represents a genuine doubt as to the possibility of having "docile, externally controlled workers in industry, who are yet free, intelligent and responsible members of a democracy outside it," the result is much the same It means that the psychologist will have to take broad views of his subject if he is really to serve his day and generation as he aims at doing, and it means also that the purport of psychological experiment concerning labour factors should always be made clear to the public It is the unknown that has the terror The working psychologist could hardly begin better than by studying the valuable paper referred to in this note

[1] The Present Attitude of Employees to Industrial Psychology.

SEX DISPROPORTION AND ITS REMEDY

THE occurrence of males and females of the human species in almost exactly equal proportions, whether the white, yellow, or black varieties be considered, is a natural phenomenon of considerable significance The disturbance of this normal ratio by such accidents as warfare and emigration is well recognised by sociologists as a factor of serious importance The last annual report of the Friends Association for the Promotion of Social Purity, for example, is constrained to admit the influence of war losses, even while it points out that the disproportion will be considerably less in five years' time There can be no doubt that an excess of women in the population conduces to irregular living, with its attendant diseases amongst those of a low moral standard Others whose lives are regulated by the ideals taught in Christian countries may be expected to suffer psychically through the inevitable conflict between their sense of right and their unsatisfied sex instinct Especially is this true, as has been shown by Professor Jung,[1] in a civilised community where other fundamental instincts like that of self preservation find no outlet for their affective energy There is, however, another way of looking at this question In those countries where a diminishing population is a source of grave anxiety to their most patriotic citizens the loss of thousands of potential fathers is a most serious aspect of the post war sex ratio Dr Paul Carnot[2] estimates that this loss will result in the sterility of two million women in France, and supposing that each of these women might have borne three children, he calculates that the State will lose six million citizens in this generation France, he says, cannot afford such a depletion, and he puts forward certain tentative suggestions for repairing the gap One suggestion —less radical than others—is that facilities should be offered to foreigners enabling them to assume French nationality when they are married to French citizens Many soldiers from all parts of the world have claimed French brides in the last few years, but it is doubtful if any large proportion will wish to establish their home on foreign soil, and Dr Carnot is not satisfied that such a change in French law will suffice He is prepared to go much farther.

> 'No convention, moral or social" he says, "seems to us sufficiently rigid to deprive impoverished France of six million births" The real solution must be sought through some method of making motherhood a remunerative career The State is to replace the absent "head of the family' and to bear all the expenses incidental to the birth and upbringing of a contingent of young subjects A bonus will be paid on ' products of good physical quality '

We remember the horror which was aroused in this country by the unfounded rumour that Russian women had been "nationalised," and we cannot think that Dr Carnot's scheme will readily commend itself either here or in France Fatherhood is nearly as essential as motherhood to the growing child, and we had almost rather consent to polygamy than to sociogamy The real situation seems to be that society must discover some means of maintaining its sex proportion in the natural ratio of one to one If war cannot be eliminated, then women might be enlisted on the same terms as men, and, in the meantime, while so many children are in need of food, a great increase in the birth rate will have its drawbacks

ACUTE SYPHILIS OF THE KIDNEY

ACCORDING to Dr H N Cole,[1] who writes from the Department of Dermatology and Syphilis of the Western Reserve University, Cleveland, acute syphilis of the kidney is a rare disease, and the diagnosis is not justified until exacting conditions are satisfied, such as those laid down by Fournier These were (1) proof of a recent syphilitic infection, (2) appearance of nephritis with syphilis, (3) lack of other sources for nephritis, (4) characteristic features of the nephritis—viz , a rapid onset of the kidney disease, a very high albumin content in the urine, and a tendency to early uræmia Dr Cole reports a case in a man, aged 26 which satisfied all these requirements except that the patient showed no signs of uræmia. Salivation occurred after one week of mercurial inunction, and the albuminuria steadily rose, but after an intravenous injection of 0 2 g arsenobenzol the albuminuria disappeared entirely within two days

A NATIONAL INSTITUTE OF INDUSTRIAL PSYCHOLOGY AND PHYSIOLOGY

IN the current number of *The Times Engineering Supplement* a detailed account is given of the proposed National Institute of Psychology and Physiology applied to Industry and Commerce Among the names of its supporters we note those of Sir Walter M Fletcher, Sir R A Gregory Mr W B Hardy, Dr Leonard Hill, Sir Alfred Keogh, Dr C S Myers, Sir E Cooper Perry, Professor C S Sherrington, and Professor E H Starling The intention of the founders is to establish a National Institute which will investigate the human problems of industry and commerce, occupying a position similar to that held in the domain of physical science by the National Physical Laboratory It will provide training courses and lectures for those interested in the practical applications of psychology and physiology to the problems of industry and commerce It will undertake investigations at factories and offices in relation to any special problems—e g , the conditions necessary to give optimum output the methods of reducing mental and muscular fatigue, the application of tests by which workers can be selected for the occupations for which they are mentally or physically best fitted, and the conditions which tend to the health, comfort, and welfare generally of the worker The Institute will not be established for profit, and a close relation will be maintained with the Industrial Fatigue

[1] The American Journal of Syphilis January, 1920

Research Board, but overlapping of effort is to be avoided. A Scientific Committee is being formed consisting of the principal psychologists and physiologists throughout the country interested in such problems, in order to coördinate research work and, so far as possible, to support it by means of grants. We heartily wish success to so impartial and scientific a body of workers in their efforts to deal with important problems, in which a previous medical training is obviously of enormous value. The secretary of the proposed Institute is Mr. G. H. Miles, D.Sc. Lond., and its present offices are at 1–4, Great Tower-street, London, E.C. 3.

DEGREES IN SPECIAL SURGERY AT THE UNIVERSITY OF LONDON.

THE claims of regional surgery for proper recognition have become insistent. The Council of British Ophthalmologists recently expressed the opinion[1] that ophthalmology should be one of the optional subjects in which a candidate can elect to be examined for the degree of Master of Surgery of a university. In a presidential address[2] delivered at the end of last year before the Section of Otology of the Royal Society of Medicine Mr. H. Tilley regretted that London stood almost alone amongst the universities of the United Kingdom in not requiring from its students some certifiable knowledge of diseases of the ear, throat, and nose, and that it offered no inducement to advanced study by allowing candidates to elect these subjects for examination for the highest degrees. That is now to be changed. The Senate of the University of London has sanctioned two new branches in which students may proceed to the degree of M.S.—namely, ophthalmology (Branch III.) and laryngology, otology, and rhinology (Branch IV.). Candidates for admission to the examination in either of these branches must normally have taken the degrees of Bachelor of Medicine and Bachelor of Surgery at the University of London not less than two years previously, and the usual certificates of study and practice in the subjects of examination and service in approved appointments are to be produced. Certificates are accepted only from those schools approved by the University for the purpose, and hospitals desiring their teaching and appointments to be so approved are invited to apply to the academic registrar (South Kensington, London, S.W. 7), from whom the detailed regulations may be obtained. London has thus put itself in line as regards special diplomas with other teaching centres.

Dr. Dawson Williams, editor of the *British Medical Journal*, has been made Commander in the civil division of the Order of the British Empire in recognition of his valuable services to the Royal Army Medical Corps throughout the war.

THE WELSH HOSPITAL FUND.—The winding-up of the Welsh Hospital at Netley is to be of benefit to the Welsh National School of Medicine. This hospital was founded and maintained for war purposes by funds raised from Welsh people in Wales and without; during its existence 9763 patients were admitted. The total income amounted to £87,729, and by good management the expenditure for the four and a half years was £78,040. The balance is now to be devoted to establishing and maintaining 18 scholarships of £25 each per annum at the Welsh National School of Medicine, open to "any person who is or has been for seven years prior to the date of election resident in Wales (including Monmouthshire), or a child or grandchild of a person born of parents resident in Wales (including Monmouthshire) at the time of such person's birth."

THE PHYSICAL CENSUS.[1]

II.

IN a previous article the figures were given of certain localised districts, in connexion with Keith's standard. To what extent can these figures be accepted and made the basis for action? Can we, in the first place, safely compare the figures and percentages yielded by different districts and different towns and occupational groups? In other words, can we admit a disparity in the standards adopted by the different medical boards so considerable as to render it impossible to arrive at sound conclusions? To this it must be answered that the findings are based not upon general impressions as to the fitness of the men but upon the results of actual measurements capable of being expressed mathematically (height, weight, age, relationship of girth of chest to height, &c.). And it must be recollected that every endeavour was made to establish uniform procedure both by published instructions, by giving a common training to the heads of the medical boards from all parts of the country, and by periodical conferences regarding moot points. This being the case, the wide divergences found between the statistics of two cities such as Leeds and Sheffield, situated in the area administered by one district commissioner must have an actual basis of fact.

A disturbing influence of greater importance is the variation in the different areas in the number of men engaged in protected occupations who were called out or "combed out" during the last year of the war. Take, for example, the two cities just mentioned. The industries of Leeds are such that in that city there were relatively few men belonging to protected occupations. The natural tendency had been for those who were strong, keen, and physically fit to volunteer in the early years of the war; from which it follows that the men called up in the fourth year represented largely the dregs of a population exhausted by three years of war. The industries of Sheffield, on the other hand, were of the first importance to the nation for the prosecution of the war; they were highly protected. The final combing out therefore elicited the appearance of an undue number of men who were physically fit. No deductions can be drawn regarding the manhood of these two cities without these facts being kept in mind. We cannot neglect noting that the four occupations which stand highest in the report—namely, agriculture, (coal) mining, engineering, and iron and steel-work—were all highly protected. Nevertheless, and making every allowance for these considerations, we cannot satisfy ourselves that all is well.

There is a grave and disturbing factor to which, we think, sufficient attention has not been drawn in the Report. We refer to the relationship between age and physical efficiency. Professor Keith based his indexes upon measurements taken from a select population of undergraduates in the prime of physical life between the ages of 18 and 25, the majority between 18 and 20. Unfortunately, we possess no adequate body of data by which to establish when the average healthy man is at his physical prime, or by which we can plot out the curve of the age-efficiency relationship. But this we know, as the result of practical experience, and notably from the findings of the boards determining admission to the Air Force, that already at the age of 24 there is to be noted in general a decline of physical fitness. The Report, indeed, yields figures indicating that the maximum is at 18, with relatively rapid descent after this age. Thus Liverpool No. 1 Medical Board reports (p. 57):—

Grading of 25,696 Recruits (Nov. 1st, 1917–Oct. 31st, 1918).

Grade I. Men.

Year.	Number passed.	Percentage.	Year.	Number passed.	Percentage.
18	2146	49·5	26–31	747	27·7
18–19	2354	48·9	32–37	617	20·9
20–25	823	35·2	38–42	277	8·9

It is obvious, therefore, that in a population of recruits which in respect to age is mixed, as was that presenting itself for examination in 1917–18 the index of fitness must vary according to the ages of the individuals forming the various groups, and that the inclusion of even a few men aged between 40 and 50 must materially lower the average The Liverpool district appears to have taken this variable into fullest account, although in other parts of the North Western District, as at Stockport and Salford, valuable data are given bearing upon this subject, and (pp 78–82) the West Midland region gives confirmatory graphs showing the progressive decline in Grade I men from 18 years of age onwards The decline is even more rapid in agricultural areas, like Hereford and Leamington, than it is in industrial areas such as Birmingham and Coventry

---

[1] THE LANCET, March 6th, p. 557, and March 27th, p. 726.

But making these admissions, the fact remains that, selecting what from a physical standpoint is evidently the best group, in a painfully large number of districts that group is below par Thus in Liverpool the 18 year old group is 49 5, in Birmingham, 36 0 Burslem, 27 0 Dudley, 21 9, compared with the expected 70 of Keith's index, the 75 per cent and 63 per cent respectively of those under 18 and between 18 and 21 of the Edinburgh district, the 80 62 per cent of Scottish miners from 18 to 21 years of age, and 86 18 per cent Grade I among young Scottish nonworkers Even, therefore, at the most favourable life period there is in many districts a deplorable lowering of the efficiency of British manhood, a lowering so great that it is a national need for it to be arrested What are the main causes can be deduced from a study of the other end of the tables given—namely, of the rejected Grade IV men Regarding these, in district after district we encounter the same story—poor physique, tuberculosis, heart disease Wholly preventable conditions, malnutrition, and the chronic and subacute infections are, in the main, responsible for the sapping of the vitality of British young manhood Three fifths of the rejections are due to these causes And when we inquire further as to the underlying cause it appears evident that the lowest number of Grade I men and the highest percentage of rejections are associated with overcrowding, back to back houses and lack of ventilation, female labour with its concomitant neglect of the growing child, and poor feeding of the population in general The food is there, but it is not prepared aright, nor is there adequate selection of the necessary constituents We must add to these the widespread lack of exercise and physical training of the growing child and the youth, for 90 per cent of our population has no proper recreative exercise

Attempt has not been made here to do more than explain certain bearings of a report which should be in the hands of every public official however remotely connected with the health of the nation, and also in the possession of every medical man The significance of the statements, records, and diagrams can only be realised by personal study, but an idea of the valuable work which has been discharged is furnished by the first table in the report It has been universally quoted, but its message has not been grasped From this it will be seen that the actual number of medical examinations made amounted to 2,425,184, the figure including re examinations, so that the same individual may figure several times in the total This figure, when divided in accordance with the grades, shows that 36 per cent were placed in Grade I, 64 per cent of the population of military age failing to attain the full normal standard of health and strength necessary for enduring the physical exertion suitable to age 22 to 23 per cent, or approximately 1 in 5, were placed in Grade II, and were thus estimated as being capable only of undergoing physical exertion of a limited kind 31 to 32 per cent, while presenting marked physical disabilities or evidence of past disease unfitting them for the higher grades, were considered useful material in an army made up of every sample of the population, for occupations such as tailoring and bootmaking, as well as clerical assistance, while rather more than 10 per cent were totally rejected From the medical point of view the large percentage of men placed in Grade III is alike the most ominous and the most hopeful, ominous because the figure is a representation of our want of appreciation of the past of many of the problems of public health, but optimistic in that here lies that great class whose physical condition can be bettered by the intelligent labours of a Ministry of Health The opportunity should be seized while it lies ready to hand, to examine carefully the material which events of recent years have placed within our reach, with the assurance that though we may not possibly achieve the whole truth we can yet find much that will throw an illuminating light on our greatest national asset—the health of the population

IRELAND

(FROM OUR OWN CORRESPONDENTS)

Medical Practice under "The Curfew"

"The Curfew —that is to say, the prohibition of being abroad between the hours of 12 midnight and 5 in the morning—has now been in force in Dublin and the neighbourhood for some five or six weeks, and it is possible to consider the effect it has had on the conditions of medical practice It is to be noted that the authorities promised to grant permits to medical practitioners and nurses and other persons having legitimate business abroad during the prohibited hours, and so far I have not heard of any refusal to proper applications It was anticipated that even with permits it would not be very safe to be out of doors in the small hours One remembered the days after Easter week in 1916 when—all others being forbidden to go out after dark—it was permitted to doctors and nurses to go about on their lawful occasions But the inquiry as to the personality of the wayfarer was as likely to follow as to precede a rifle shot in his direction, and one distinguished clergyman was killed in this way through having mistaken the time by a few minutes When the present restrictions were imposed a large body of public servants —the telegraph messengers—were so fearful of the dangers of the night that they declined to perform their duties, and the Postmaster General admitted in the House of Commons that their reluctance was "not unreasonable' As a matter of fact, the authorities here, as far as my information goes, have carried out their duties of interrogating wayfarers with tact and courtesy, and no mishap has yet occurred It is true that one or two doctors who neglected to provide themselves with permits have had to spend some hours in a police station but they have only themselves to blame On the other hand, certain inconveniences to the sick have necessarily resulted In case of sudden illness unless a telephone is available—and in the present condition of the telephone service it sometimes takes more than five hours to get a message through—there is no way of summoning a doctor An observant journalist who walks a mile home each morning tells me that in sporting phrase, "the chances are even" of being challenged, and anyone found without a permit is certain to be brought to the police station and delayed until full inquiries have been made Women making their way to maternity hospitals or requiring attendance at their homes are in special difficulty A messenger may be unable to reach his destination, and in one case at least a woman in labour was turned back when within a stone's throw of the hospital The sentry, in the stolid performance of his duty, held that "labour' must cease between 12 and 5'

In spite of the disturbed condition in country districts there does not seem to have been much interference with medical practice In one case some weeks ago in county Clare a medical man arriving in his car on the scene where a "battle had just taken place between a police patrol and an attacking party was fired on by the police under the idea that the car was coming up in support of the enemy He was wounded in the forearm, but not seriously On the whole, medical men do not appear to suffer more than other peaceful citizens from the disturbed conditions

The late Professor Joseph Patrick Pye

A distinguished teacher and an impressive personality has passed away in Professor Pye professor of anatomy and physiology in University College, Galway. His whole life was associated with the College in Galway. He studied medicine there as a student in the "sixties." Having qualified as L.R.C.S. of Edinburgh in 1870 and taken the medical degree of the old Queen's University in 1871, he was, after some work in London and Paris, appointed professor of Materia Medica in Galway in 1873. In 1877, when Professor Cleland, on appointment to Glasgow, resigned the Chair of Anatomy and Physiology in Galway, Pye succeeded him and filled the two chairs for the 43 years up to his death at the age of 71. His many friends often regretted that he attempted the double duty for so long a period, for he was prevented by his full routine of duty from securing wider recognition as a man of science, but in Galway his originality and insight made him a successful and inspiring teacher. He was held in much affection by his students.

Puerperal Fever in Belfast.

An inquiry has been held in the City Hall, Belfast, by a medical inspector of the Local Government Board, requisitioned by reason of the number of notifications of puerperal fever in the months of December, 1919, and January and February, 1920. It appeared that 21 notifications had been received by the public health department. The public health committee asked the Local Government Board to investigate the facts. Four of the cases were, it was stated, in hospital and three dead. The medical officer of health said four cases were attended by one nurse and notification by her was prompt; she had attended other cases in the same period where no disease had supervened, and he was satisfied there had been no neglect. He believed the infection in the four cases went from one to the other, but the nurse would have no knowledge of the existence of the fever. He said the abnormal system of living during and since the war might have affected people's nerves, so that they had not the same resisting powers as formerly. In the fatal cases there was no overcrowding. He believed the nurse with the four cases did everything she could, and was in no way to blame. Evidence was then taken from doctors who had been in attendance on the cases under investigation. One said it was unfair to private practitioners that nurses with doubtful qualifications should go and make examinations and tell the people it was unnecessary to call in a doctor. He was satisfied that lots of cases of puerperal fever could be avoided if the cases were attended properly. Another doctor said the incidence of influenza had, in his opinion, a great deal to do with these cases of puerperal fever; while another—a former house surgeon in the maternity hospital—said his experience for two years in that institution was that the great majority of cases were due to treatment by "handy women." The medical officer of health, on being re-examined, said he knew some midwives were illiterate and got friends to fill up the notification forms. He had one case in mind where the taking of the temperature was guesswork. The town solicitor said that under the present Act midwives were appointed by the Central Midwives Board, Dublin, and that suggestions as to qualifications by the Corporation had been rejected. The lady inspector superintendent of midwives in the Belfast Public Health Department said, with one exception, all the midwives had carried out her instructions. In connexion with handy women certified under the Corporation Act, she had in a number of instances instructed them in the recording of temperatures and pulse, and the taking of the latter was the greater difficulty. The midwives concerned gave evidence, when one said she could not get a doctor to come to a case, and she could not order removal to hospital, as without a doctor's signature the ambulance would not appear. In another case, until the doctor was paid, he would not come. She said that unless they were engaged to attend doctors would not come. Another midwife, who worked among the poor, said doctors, unless paid their fee, would not come. The inspector said the nurse who had the four cases of puerperal fever had exercised scrupulous care. At the conclusion of the evidence the Belfast City town solicitor said the evidence showed that in almost every case there had been laxity in regard to notification of birth (which should be given within 36 hours), and notification of puerperal fever should also be given at once. With reference to the capacity, knowledge, and training of midwives, "it was," he said, "a dismal thing for the country that the law was passed abrogating the Corporation (viz., Belfast) Act of 1911, and opening the door again to a considerable influx of practically untrained women. Fortunately, that door was now closed as the two years since the Act of 1918 had elapsed, and women of that untrained type could not now be admitted." He said that the nurse who attended the four puerperal cases was the only one who had given notification with promptitude.

Ulster Medical Society.

A meeting of this society was held on March 25th in the Medical Institute, Belfast, Mr. Andrew Fullerton, the President, being in the chair, when Dr. N. C. Graham read a paper on a Typhoid Epidemic in a Sanatorium. The epidemic began on August 17th, 1919, in the Forster Green Consumption Hospital, Belfast, and, during its progress, 21 persons (patients, nurses, and maids) were affected. At first no clue to its causation could be found either in water, milk, or carriers. Later a phthisical patient, who was discharged with high temperature as he was thought to be dying, recovered, and it is believed that he may have had typhoid and that others may have been infected. After the epidemic was over a maid was found with typhoid bacilli in her urine, and she may, perhaps, have been the "carrier." Dr. Graham quoted details of a similar outbreak in a tuberculosis sanatorium in America, and in both places, while Widal's reaction was definite, the typhoid symptoms were not marked among those affected. Dr. G. M. Irvine read a paper on Medical Art in Relation to Social Progress.

March 29th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The New Rector of Paris University.

THE death of Vice-Rector Lucien Poincaré has been made the occasion of an administrative innovation, for Professor Appell, ex-Dean of the Faculté des Sciences, has been nominated as his successor. For nearly 80 years the University of Paris was the only one in France without a titular rector at its head. In theory the rector was the Minister of Public Instruction, and the real head of the University held only the official title of vice-rector, as did L. Poincaré, and Gréard and Liard before him. In the documents which he signed he was only called rector by courtesy. This fiction has now only an historical interest, and the Minister has renounced his honorary title in making M. Appell, who is a celebrated mathematician and a member of the Institute, Rector in name as well as deed.

Gratuitous Treatment of War Victims.

The law of March 31st, 1919, now coming into force in France, gives to all ex-soldiers suffering from wounds or disease due to the war the right to receive medical, surgical, and drug treatment for the remainder of their lives at the expense of the State. In this fit of generosity the State has assumed an enormous burden. Gratuities have an irresistible attraction for the public, and there will be a tendency to refer to their military service as the cause of any malady from which soldiers suffered in the course of five years of war. But in France ex-soldiers represent 80 per cent. of the male population between 20 and 50 years of age. Provisions in the law aim at providing guarantees against such abuses as can be easily foreseen. Men, even though invalided and pensioned by an official inquiry, will have to prove that the disease from which they suffer is a direct consequence of the malady or injury which gave rise to invaliding. At the express demand of the medical profession, free choice of doctor and pharmacist is definitely specified, the State paying the professional charges on a tariff to be fixed later by agreement with the medical societies. Since in view of the state of French public finance the tariff will be modest, it remains to be determined whether the doctors are obliged to accept the care of such patients Well known consultants, who at present command large fees, will be threatened with the invasion of their consulting rooms by a populace happy to make use gratuitously of their right to free choice of doctor, a right assured to them by law It is true that the doctor will have the power to decide which cases should be treated in hospital, but even so he cannot be obliged to accept all the patients who claim his care If many doctors refuse—which they certainly will do when they see the abuse of the benefits of the law by well to do clients—the statutory free choice will become illusory This difficulty, clear enough to the medical profession, does not seem to have been foreseen by the legal mind The administrative dispositions will be simple enough The names of all the men who come into the legal category will be inscribed on a special list at the town hall of their place of residence They will receive a card recording the diseases or injuries contracted during military service, with a series of leaves attached, each consisting of two parts, one for the doctor and one for the pharmacist The doctor to whom the patient applies will have to certify if he is suffering in consequence of the infirmity inscribed on the card Should he conclude in the affirmative he tears off the sheet, handing to the patient the part reserved for the prescription for him to take to the pharmacist The doctor keeps another part of the leaf called a "bulletin de visite" At the end of the quarter the doctor and pharmacist send to the prefect of the department the whole of the used leaves which constitute the vouchers for their payment At the patient's first visit the doctor writes at once to the prefect informing him that the disease is of a nature to secure the benefit of the law If he considers otherwise he simply refuses the card presented by the patient, which is as much as to say that he has no legal right to care or medicine The law does not say if the preliminary consultation is to be paid for when the conclusion is negative It will in any case involve a careful examination on the part of the doctor, and if this examination is to be paid for by the State abuses will arise on the part of less conscientious patients These are some of the minor difficulties to be foreseen in the application of the law

The Campaign against School Epidemics

M Azoulay recently complained to the Academy of Medicine that measures to ensure school hygiene are rendered difficult or nugatory by timidity and ignorance on the part of municipalities and faulty interpretation of the measures proposed He proposes the creation at the onset of any epidemic of a class of infected pupils directed by teachers and district nurses The first requisite is to remove all powers in regard to health and sanitation from the authority of the local mayors who may be incompetent and too sensitive to electoral interests

March 27th

VIENNA

(FROM OUR OWN CORRESPONDENT)

A Leaflet on Influenza

THE frequency of attacks of the new "grippe" or influenza, has caused much uneasiness amongst the population of Vienna, not a little promoted by alarming notices in the daily press as to the high rate of mortality and the serious complications, like meningitis and pneumonia The Vienna Medical Society, as the recognised authority on medical matters in this city, appointed a committee to draw up an instructive leaflet for the general public The following information has so far been published by the committee The present wave of the grippe has been prevalent for about six weeks, but neither in size nor in severity does it equal the epidemic of 1918 Hæmorrhagic cases are almost completely absent the pneumonic complications are mostly very mild Neuritic troubles, as well as protracted feverish conditions, are often noted and initial rashes resembling scarlet fever are occasionally seen The comparatively frequent cases of encephalitis myoclonica of doubtful prognosis seem to be traceable to this epidemic Children under 12 years are subject to the infection but mostly to a mild degree Even cases with a severe onset soon improve Affections of the middle ear are not very frequent, but often affections of the conjunctivæ are noted with marked inflammatory symptoms

Treatment of Ozæna by Transplantation of the Parotid Duct

At a recent meeting of the same society, Professor Meyer reported the results of a series of cases of ozæna, treated on the principles of Wittmaack This method is based on the fact that the symptom most distressing to these patients the odour, can be palliated by constant washing out of the nose Wittmaack had the ingenious idea of producing a continuous irrigation of the nose by implanting the parotid duct into the nasal cavity, thus causing the saliva to keep the nasal mucosa moist This produced a sort of liquefaction of the nasal discharge, with avoidance of crusts and absence of the peculiar odour The operation is very simple An opening is made in the canine fossa similar to that for operation on a maxillary empyema—under local anæsthesia—just opposite the duct The duct is then freed for about half an inch, with sufficient margin of mucous membrane to permit of a flap, and implanted into the maxillary antrum with a few stitches It quickly resumes its function, and saliva appears in the nose especially at meals In one of the cases the profuse flow caused more inconvenience than the ozæna before operation, and this patient had the operation "undone" because of the profuse salivation the previous condition was easily restored But the majority of the other five patients greatly benefited The time that has elapsed since the introduction of the operation is not long enough to say what permanent benefits will be derived from it

The Vacant Gynæcologic Appointments in Vienna

By the unexpected death of Professor Ernest Wertheim, chief of the First Women's Clinic in Vienna University, an unusual condition has been brought about Since the death of Professor Schauta, about one and a half years ago, his clinic had not been in charge of a clinical teacher, but was carried on temporarily by his last assistant Now Vienna is without clinical teaching in obstetrics and gynæcology To fill the vacancies is most urgent Proper professors are hard to find The sort of man required is a scientist of high standing, and at the same time a good teacher while he will have to be very modest in his demands, for the Government seem not to have enough funds to offer satisfactory remuneration It has been planned for some time to unite both clinics in one institute but to this idea all students are opposed As present conditions seem to preclude the appointment of an eminent teacher from Germany, probably one of the leading gynæcologists of Vienna like Halban or Peham will be asked to accept the office

Professor Wertheim

Professor Wertheim's death came as a shock to his numerous friends and many beyond our frontiers will learn with regret of his passing His operation for cancer of the uterus had gained him a wide fame Wertheim was a keen and bold operator, as well as a critical and cautious scientist, whose researches were distinguished by logic and method He was the first to prove that the gonococcus was responsible for the majority of infections of the female pelvic organs, and to demonstrate its cultivation by adding human serum to the agar medium His researches on the anatomy and histology of the pelvic organs and their lymphatics made possible the exact removal of cancerous deposit and students from both hemispheres flocked to his clinic to follow his methods At the early age of 56 years he fell victim to the wave of influenza which rapidly ove whelmed his weakened heart

Homage to William Osler

At a recent meeting of the Medical Society of Vi Professor K F Wenckebach delivered a funeral o on Sir William Osler whose death roused worl feeling among the medical fraternity. We in Vienna felt his decease the more keenly, as it was due to his active intervention that our hospitals, some six months ago, received a generous gift of remedies and food from England at a time when conditions were alarming. It will be remembered that Professor Wenckebach visited London at that time and was generously received there.

March 11th.

THE INCOME-TAX REPORT.

BY JOHN BURNS, W.S., EDINBURGH.

EVEN in the midst of the press of work which at present affects all the professions, most of us can spare time enough to get a general notion of how our particular cases are likely to be affected by the changes recommended in the matter of income-tax and super-tax by the Royal Commission which has been inquiring into that subject. It may well be, however, that a practising physician or surgeon would have neither the time nor the inclination to plough his way through the voluminous pages of the report in order to find out the parts which have a bearing on his affairs, and indeed it may be possible to present the position in plainer form than individual reading will attain to.

On the bulk of the medical profession the changes recommended will not impose any materially heavier burden; they may, on the contrary, in many cases be advantageous, as figures later suggest. It is convenient to assume that the recommendations will be accepted and receive legislative effect, although that depends on the Chancellor and the House of Commons.

The Assessment Basis.

Instead of an average of three years the basis is to be the ascertained income of the last year earned in practice. There may be hard cases in the act of transition from the one basis to the other. Some provision is to be made to meet such cases. It may take the form of a rigid rule, or it may possibly issue as a discretion to some official body to give relief when the circumstances seem to justify it. In passing it may be said that there is just a little too much savour of bureaucracy about the Commissioners' recommendations. In any case, this transition point is a technical matter which will in many cases require careful watching. The "preceding year," of course, means the last year for which the doctor has, in fact, made up his accounts. Thus, assuming that the new rule operates for the tax year April, 1920, to April, 1921, the assessment for that year would be upon the ascertained professional results for the doctor's year to, say, Dec. 31st, 1919, if that is the date on which he has been in the habit of making up accounts. There is no suggestion that the option of taking either the earnings basis or the cash basis is to be interfered with.

Remuneration from official appointments will continue to be assessed on the basis of its amount in the actual year of assessment, and neither on an average nor on last year's figure. In connexion with such appointments it is important to note that remuneration in kind is to be brought into account at its fair cash value. That is because, though it cannot in fact be turned into cash, it has in most cases a substantial cash value to the receiver; yet up to date it has escaped. The reference is to such matters as free official residences, free board, attendance, &c.

It may also be well to state that, to reach total income, the unearned income (henceforth to be known as "investment income") is brought in at its amount in the year of assessment. There is an exception in the case of interest and dividends (e.g., on war loans) received without deduction of tax, which is taken at last year's figure, and there is no indication of change there. This refers to the doctor's own investment income and also his wife's, for the Commissioners do not accede to the argument that, for income-tax purposes, husband and wife ought to be reckoned as two.

Earned income relief.—At present this relief is given in the form of a lower rate of tax on the earned income, so long as the total income does not exceed £2500. This is now to be entirely changed. There is to be no limit of income which shall exclude the wealthy man from this relief. But the relief itself is not to extend beyond £2000 of earned income, no matter how large the earned income may be. The form of relief is by subtracting one-tenth from the earned income and bringing into the taxation account only the remaining nine-tenths. Thus a professional income of £500 will count as £450, £1000 as £900, £2000 as £1800, £3000 as £2800. The amount that escapes can never exceed £200 of income.

Abatements.—Here we refer to what up to now have been known as the abatements for small incomes, the last being £70 on incomes exceeding £600 but not exceeding £700. All this is to be changed. The relief is now to be known as the "personal" or "marriage" allowances. The amounts are £135 to an unmarried person, including widows and widowers, and £225 to married couples living together. These allowances are given without any limit of income. The wife allowance disappears, for it is merged in the marriage allowance.

Children.—The conditions as to age remain as at present. The amounts are £40 (as at present) for No. 1, and £30 (instead of the present £25) for each other. No limit of income. The allowance is not to be given in respect of any child who has an income as large as the allowance. It is assumed that it will probably be found that, if a first child has an income of £15 an allowance of £25 could be obtained by the father.

Dependent relatives remain as at present, except that the income limit is abolished, and that the allowance may be obtained for a widowed mother, though neither old nor infirm.

Two things may be noted about all the allowances mentioned. There being no limit of income every doctor must be affected by all, or at least by one of them. They operate as actual deductions from income. It is only after they are taken off that what is now to be known as the "taxable income" is ascertained.

Graduation of tax.—This is retained, but in a much less complicated form than at present. Having found the taxable income, it is taxed as follows: (1) the first £225 at one-half of the standard rate of income-tax, and (2) the balance at the standard rate. At present that would mean 3*s.* on £225 and 6*s.* on the balance. Again, this holds no matter how large the total income may be.

Life assurance.—This becomes rather involved. Policies effected since June, 1916, rank for only one-half of the standard rate of tax, which is the present rule. Policies taken out before that date rank for the full standard rate of tax if the income exceeds £2000; for three-fourths of the standard rate if the income exceeds £1000 but does not exceed £2000; and for one-half of the standard rate if the income does not exceed £1000.

Illustrations.

No. 1.—An unmarried man.

Professional income on last year's basis	£700
No other income. Deduct one-tenth..	70
	630
Personal allowance...	135
Taxable income...	£495

Taxed at 3*s.* on £225 and at 6*s.* on £270.

No. 2.—A married man with wife and four children counting for the children abatement; also one dependent relative:—

Professional earnings (practice)		£3000
Deduct the maximum earned income relief... ...		200
		2800
His investment income		500
His wife's ,, ,, ...		500
		£3800
Deduct:—		
Marriage allowance	£225	
Children, £40, £30, £30, £30	130	
Dependent relative	25	= 380
Taxable income...		£3420

Taxed at 3*s.* on £225 and at 6*s.* on £3195. But if he pays premiums of £200 on pre-1916 policies and of £300 on post-1916 policies, he will obtain relief at 6*s.* per £ on the £200 and at 3*s.* per £ on the £300.

Depreciation —This will now be obtainable as a deduction in respect of a car But it will be for consideration whether it should be claimed, or whether it may not be better to continue to charge renewals as at present In either case all repairs, and, of course, the running expenses, are allowable As between depreciation or renewals either may be obtained, but not both

Residence —The present rule is that when the same premises are used as dwelling house and for practice not more than two thirds of the Schedule A assessment is an allowable expense It is suggested that there be, in future, power in a proper case to allow more than two thirds What will be regarded as a special case remains to be seen There have been some very hard cases in the line of boarding houses, where the trader and family did not occupy more than a twentieth of the whole But the doctor s grievance, as put before the Commission, rather was that, if it were not for compelling professional necessity, he would reside in a much less expensive neighbourhood and in a much less pretentious residence The suggestion, therefore, was *that in such a case, even though the professional* part of the house might be much *less* than two thirds, it would be reasonable to allow *more* than that fraction as a professional expense The point should not be forgotten in the class of case to which it applies

Professional books —This is a matter which has been referred to in these columns previously The practice at present varies It ought now to be cleared up and pressed in Parliament if necessary A sufficient reason is that the Commissioners recommend an allowance of £20 to schoolmasters for books, assuming that they spend so much If a schoolmaster requires £20, would £50 be too much for a doctor?

Partnerships —Each partner may in future be separately assessed this is to secure privacy but there will be a right on the part of the Crown to claim against the partnership if any partner does not pay

Casual gains —It is recommended that ordinary Stock Exchange gains should be reckoned as taxable income This is totally novel But losses would not be deductions against ordinary income

Super tax —The changes are not very great It is to begin absolutely at any income over £2000 The rates are somewhat increased The scale is carried up to £20,000 Bonus shares are to be roped in

Specimen figures of tax —The following tables include super tax where payable When children are referred to what are meant are such children as count for the children allowance To save space it is assumed that the income is all earned, but even if not the difference is not very great

THE LATE MR H T. SYLVESTER, V C —Mr Henry Thomas Sylvester, who died recently at Paignton, Devon, took his L R C S Edin in 1853, and was for 30 years in the employ of the East India Company as surgeon It was whilst serving with the Royal Welsh Fusiliers that he won the V C for rescuing a brother officer under heavy fire being also mentioned for "devoted goodness to the wounded under his charge" He was a Knight of the Legion of Honour, and also was awarded the Turkish medal, medal and clasp for Sebastopol, and also the medal with clasp for *Lucknow* After his retirement from the army Mr Sylvester practised in London, retiring later to Paignton

The Services.

ARMY MEDICAL SERVICE

Lieut Col J F Martin relinquishes the temporary appointment of Deputy Assistant Director General

Major and Bt Lieut Col H V Bagshawe to be a Deputy Assistant Director General

ROYAL ARMY MEDICAL CORPS

Capt E W Vaughan to be temporary Major whilst specially employed

The undermentioned relinquish the acting rank of Major Capts O B Pratt, J R N Warburton, Temp Capts J Bamforth, G F Bird

Capt T J Kelly resigns his commission

T W Smart to be temporary Lieutenant

Officers relinquishing their commissions —Temp Hon Lieut Col W R Dawson (retains the honorary rank of Lieutenant Colonel), Temp Majors (retaining the rank of Major) C V Mackay, H D Macphail, Temp Capt A J Blake (granted the rank of Lieutenant Colonel), Temp Capt (acting Major) N Dunn (granted the rank of Major), Temp Capts (retaining the rank of Captain) J M Morris, W G Riley, J P Crawford P L Hope, F D Johnson J N G W McMorris, E Hesterlow, W J Lascelles, F W Watkyn Thomas

SPECIAL RESERVE OF OFFICERS

Capt J E E de Robillard resigns his commission

TERRITORIAL FORCE

Capt (acting Major) A C Watkin relinquishes the acting rank of Major on ceasing to be employed

Medical Branch —The undermentioned are transferred to the unemployed list Capt (acting Major) H Gardiner Hill Capt (acting Lieut Col) W Darling

VITAL STATISTICS

VITAL STATISTICS OF LONDON DURING THE YEAR 1919

IN the accompanying table statistics of sickness and mortality in the City of London and in each of the metropolitan boroughs are summarised for the 53 weeks of the year 1919 With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the ten diseases specified in the table was equal to a rate of 5 9 per 1000 of the population, estimated at 4,358 309 persons, in the three preceding years the rates were 5 1, 4 2, and 4 4 per 1000 respectively Among the various boroughs the rates last year ranged from 2 9 in Hampstead, 3 0 in the City of London 3 7 in the City of Westminster, 4 0 in Hammersmith, and 4 1 in Kensington, to 6 9 in Hackney, 7 8 in Deptford, 8 4 in Greenwich, 8 5 in Southwark, 8 9 in Stepney, and 10 1 in Bethnal Green Twenty six cases of small pox were notified last year, against 11, 1, 0, and 35 in the four preceding years, of these, 10 belonged to St Pancras, 4 to Woolwich, 3 to Battersea, 2 to Islington, and 2 to the Port of London The prevalence of scarlet fever showed a considerable increase last year, 12,931 cases were notified, against 6110 and 6811 in the two preceding years Among the metropolitan boroughs the greatest proportional prevalence of this disease was recorded in Stepney, Southwark, Lambeth, Deptford, Greenwich, and Lewisham The Metropolitan Asylums Hospitals contained 2841 scarlet fever patients at the end of last year, against 1246 and 1087 at the end of the two preceding years, 11,750 new cases were admitted during the year, against 6056 and 6676 in the two preceding years Diphtheria was somewhat more prevalent than in the preceding year, 9479 cases were notified, against 8300 and 8174 in the two preceding years This disease was proportionally most prevalent in Hackney, Bethnal Green, Stepney, Southwark Greenwich, and Woolwich The number of diphtheria patients remaining under treatment at the end of last year in the Metropolitan Asylums Hospitals was 1845 against 1656 and 1039 at the end of the two preceding years, the number of new cases admitted during the year was 9053, against 8554 and 8256 in the two preceding years The prevalence of enteric fever was slightly less than in the preceding year, but was considerably below other recent years, 344 cases being notified, against 779, 647, 463, 452, and 358 in the five preceding years The greatest proportional prevalence of this disease was recorded in Kensington, Chelsea, Stepney, Poplar, Greenwich, and Woolwich The number of enteric fever patients admitted into the Metropolitan Asylums Hospitals during the year was 215, against 470 446 324, 271 and 242 in the five preceding years, 25 cases

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING THE YEAR 1919.

(*Specially compiled for* THE LANCET.)

Cities and Boroughs.	Estimated civil population, 1919.	Notified Cases of Infectious Disease.												Deaths from Principal Infectious Diseases.									Deaths from all causes.	Death-rate per 1000 living.

* Including membranous croup.

remained under treatment at the end of the year, against 68, 50, 37, 32, and 23 at the end of the five preceding years. The greatest proportional prevalence of erysipelas occurred in Stoke Newington, Shoreditch, Bethnal Green, Stepney, Poplar, and Southwark. The 313 cases of puerperal fever notified during the year included 35 in Fulham, 31 in Wandsworth, 29 in Islington, 19 in Southwark, and 17 each in Hackney, Poplar, and Lambeth; in the two preceding years the notified cases of this disease numbered 199 and 158. The 197 cases of cerebro-spinal meningitis included 16 in Islington, 16 in Poplar, 13 in Wandsworth, 12 in Stepney, and 12 in Lewisham; while of the 93 cases of poliomyelitis 9 belonged to Wandsworth, 8 to Camberwell, 7 to Lambeth, and 6 each to Hammersmith, Hackney, Poplar, and Battersea.

The mortality figures in the table relate to deaths of civilians actually belonging to the various metropolitan boroughs, and are obtained by distributing the deaths in institutions among the boroughs in which the deceased persons had previously resided. During the 53 weeks ended Jan. 3rd last the deaths of 59,255 London residents were registered, equal to a death-rate of 13·4 per 1000; in the three preceding years the rates had been 14·3, 14·7, and 18·6 per 1000. The lowest death-rates last year were 11·2 in Hampstead, 11·2 in Wandsworth, 11·4 in Lewisham, 12·1 in Fulham, 12·2 in Woolwich, and 12·4 in Camberwell; the highest rates were 14·9 in Kensington, 14·9 in Southwark, 15·2 in St. Marylebone, 15·2 in Finsbury, 15·7 in Shoreditch, and 16·2 in Holborn. The deaths from all causes included 2937 which were referred to the principal infectious diseases; of these 5 resulted from small-pox, 359 from measles, 145 from scarlet fever, 777 from diphtheria, 220 from whooping-cough, 59 from enteric fever, and 1372 from diarrhœa and enteritis among children under 2 years of age. The death-rates from these diseases in the aggregate ranged from 0·3 in Hampstead, in the City of London, and in Lewisham, 0·4 in the City of Westminster, in Holborn, and in Wandsworth, to 0·9 in Hackney, in Stepney, in Poplar, in Southwark, and in Bermondsey, 1·0 in Shoreditch, and 1·3 in Bethnal Green. Of the 5 deaths from small-pox 2 belonged to Woolwich, and 1 each to St. Pancras, Islington, and Stepney. The 359 fatal cases of measles were less than a quarter of the average number in the five preceding years; this disease was proportionally most fatal in Chelsea, St. Marylebone, Finsbury, Shoreditch, Bermondsey, Deptford, and Greenwich. The 145 deaths from scarlet fever were 57 below the average number; the greatest proportional mortality from this disease was recorded in Chelsea, Lambeth, Deptford, Greenwich, and Lewisham. The 777 fatal cases of diphtheria were 113 in excess of the average number; this disease showed the greatest proportional fatality in Stoke Newington, Hackney, Bethnal Green, Poplar, Southwark, and Lambeth. The 220 deaths from whooping-cough were about one-fifth of the average number; the highest rates from this disease were recorded in Stoke Newington, Hackney, Poplar, Greenwich, and Woolwich The 59 deaths from enteric fever were 45 fewer than th average number, and included 6 in Stepney, 6 in Poplar 5 in Woolwich, and 4 in Lambeth. The 1372 deaths from infantile diarrhœa and enteritis were 612 below the average the mortality from this disease was greatest in Kensington Hammersmith, Shoreditch, Bethnal Green, Stepney, an Southwark. In conclusion, it may be stated that th aggregate mortality in London last year from these principa infectious diseases was 48 per cent. below the average.

SCOTTISH VITAL STATISTICS FOR 1919.

The figures for 1919—to which reference is made in preface to those for the last quarter of that year—show a rising birth-rate, an unusually high marriage-rate, and normal death-rate. Births numbered 106,263, being some 770 more than the previous year. Marriages numbered 44,126, the highest registered in any year since the institution of nationa registration. The previous maximum was 36,233 in 1915 Deaths numbered 75,141, which is 404 more than the mean o the preceding five years, but 3231 less than those for 1918 The birth-rate for the year was 21·7, the marriage-rate 9·0 and the death-rate 15·4 per 1000. The infantile mortality was 101·6. Deaths from phthisis were remarkably low, only 88 per 100,000, the lowest yet recorded. Those from all forms of tuberculous disease showed also marked reduction—129 per 100,000—also the lowest on record. The deaths from cancer show an increase, and now outnumber those from phthisis by approximately 32 per cent. The death-rate from the principal epidemic diseases amounted to 0·92 per 1000.

For the last quarter the birth-rate was as high as 27·9 per 1000, the marriages had increased to 9·2, and the deaths had fallen to 13·1. The infantile mortality was only 74, and deaths from epidemic diseases 0·8 per 1000.

MEDICAL LITERATURE FOR VIENNA.

To the Editor of THE LANCET.

SIR,—We have received from Professor Wenckebach sad news concerning the state of Vienna and Austria. Professor Wenckebach, although he accepted the call to Vienna but a short time before the war, has felt it his duty to abide with the suffering people who honoured him in the days of their prosperity. On the general misery of Austria in material needs it is not our purpose to dwell—it is but too well known; the Professor's appeal is for the intellectual needs of a people whose souls are starving. In their penury he says that not a farthing can be had for books or journals, home or foreign, so that for the last three or four years neither teachers nor students have been able to learn what is going on in academical circles. His direct appeal to Great Britain is for recent medical and scientific literature, for which students in all faculties are athirst. He describes the zest with which a group of students will pounce upon any fragment of a journal which may drift into their bare libraries.

May we, then, beg your readers not to throw away journals, books, or papers, and perhaps, furthermore, to make some little sacrifice to spare such literature for the Vienna Medical School? Professor Starling was to have joined us in this appeal, but left for Bombay before his signature was secured. Packets for Professor Wenckebach may be sent to Messrs. Schenker and Co., of 93, Bishopsgate, London, E.C., who have kindly undertaken to forward them in bulk to his care. Any small donations towards transport would be thankfully received by the firm.

We are, Sir, yours faithfully,
CLIFFORD ALLBUTT.
Cambridge, March 22nd, 1920. J. MACKENZIE.

LIFE ASSURANCE AND GLYCOSURIA.

To the Editor of THE LANCET.

SIR,—In a very valuable paper in your issue of March 27th Dr. R. T. Williamson states that he considers that in cases of glycosuria it is in the interest of the proposer that he should be informed why he has been rejected; and, further, that this should be done by the medical examiner. He calls attention to the rule of many insurance companies that no information as to the medical examination should be given by the medical officer to the proposer.

This rule is very wisely adopted and insisted upon by insurance companies. It is, on the other hand, frequently broken, often to the disadvantage of the company and the great annoyance of the management, both at the head office and at branches, as well as to the proposer himself. Difficult and often acrimonious correspondence may result. In the case of the occasional examiner local difficulties are easily created between the patient and his own medical attendant, or between the medical attendant and the medical examiner.

The proper course for a proposer to adopt when he is declined or postponed for life assurance is to consult his own medical attendant, and it is for the latter to make inquiries from the medical officer of the company should he fail to discover the reason for the declension or postponement of his patient's life. I have never known the refusal of permission to give the information in this way.

Very frequently the request for another examination of the urine is sufficient to induce the proposer to see his medical attendant. It is for the insurance examiner at the second interview to go into the question of whether diet or treatment have been adopted if the result of the tests should now prove satisfactory.

I am, Sir, yours faithfully,
THOMAS D. LISTER,
President, Assurance Medical Society.
Harley-street, W., March 27th, 1920.

ANÆSTHETISTS' FEES.

To the Editor of THE LANCET.

SIR,—Following on the letters in your columns from Mr. Bellamy Gardner and Mr. J. H. Chaldecott an informal meeting was held at Mr. Gardner's house of a number of representative anæsthetists to consider the question of their fees. The grievances of anæsthetists were freely discussed. Some of these are unavoidable, but others, being avoidable, ought to be removed. Of the unavoidable the chief is that an anæsthetist has to accept a case at the time and place offered or refuse it owing to previous engagements. Thus he has to refuse a considerable percentage of the work offered to him. How many other specialists are in a similar position?

The avoidable grievances are more numerous. In the first place there is no definite scale of fees that is recognised by surgeons, general practitioners, and the public. A good general working agreement in pre-war days was 10 per cent. of the surgeon's fee, with a minimum of 3 guineas. This very moderate scale was often not reached, and it is being felt now by anæsthetists that revision (in an upward direction, of course) is called for at the present time. This 10 per cent. basis is manifestly inadequate in cases such as nose, throat, and mouth operations, where exceptional skill and experience are required and exceptional risks are involved. Again, an abdominal operation is supposed to command the statutory fee of 100 guineas. In many cases, however, the surgeon agrees to reduce his fee to, say, 70 or 50 guineas, and it is at least an arguable point whether the anæsthetist, whose fees are on a much lower scale, should be expected to accept a strictly proportionate reduction.

But the main grievance of the anæsthetist is that in too many cases he is regarded as an anonymous nuisance, he is not consulted about his fee, he does not know whether he is expected to look to the surgeon, the general practitioner, or the patient for his remuneration, and falling between three stools he is either not paid at all or receives some months later a more or less adequate fee which ought to have been paid at the time of operation. I am, Sir, yours faithfully,

LLEWELYN POWELL.

PARAPHRENIA.

To the Editor of THE LANCET.

SIR,—In your issue of March 27th Dr. W. H. B. Stoddart states that chronic hallucinatory psychosis as described by me in a paper read at a recent meeting of the Medico-Psychological Association is identical with the paraphrenia of Kraepelin. It is not easy to go fully into the differential diagnosis within the limits of a letter. It may, however, be pointed out that in chronic hallucinatory psychosis the patient is the subject of hallucinations for a long period, in some cases even for many years, before delusions develop. In the second stage delusions are formed which are the logical result or explanation of the hallucinations. So far as my experience goes there are these two stages only. In paraphrenia there are at least three stages. The first is the period of "false interpretation" in which the patient has vague delusions of persecution. "The second stage occurs *some years later*, and is characterised by the development of hallucinations of hearing." The quotation is from Dr. Stoddart's book; the italics are mine. In the third stage delusions of grandeur develop.

In my paper I pointed out the similarity of chronic hallucinatory psychosis and chronic hallucinatory insanity of alcoholic origin. Dr. Stoddart in his book gives the differential diagnosis of this latter disease from paraphrenia in the following words: "In this disorder hallucinations occur in the earlier stages and appear to be the foundation of the delusions, whereas in paraphrenia hallucinations appear late in the course of the disease as a kind of crystallisation of the delusions." This sentence summarises the position excellently as regards chronic hallucinatory psychosis and paraphrenia. With regard to melancholia and dementia præcox I pointed out how unsatisfactory it was that many clinicians put the cases I had in mind in these groups, and I gave in detail the differential diagnosis.

I quite agree that psycho-analysis would be most harmful in patients suffering from well-marked delusions of persecution or grandeur described by Kraepelin as cases of paraphrenia. On the other hand, in the first stage of chronic hallucinatory psychosis the sole symptom is the presence of hallucinations. These, in my belief, develop owing to mental conflict, and repression; and then it is that psycho-analysis is likely to be beneficial. As Dr. Stoddart was unavoidably prevented from hearing the paper read, he is no doubt relying on the report of the meeting in THE LANCET of March 20th. This, of course, is very condensed. The paper will appear in full in the next number of the *Journal of Mental Science*, and if, after studying the clinical details of those patients who are given as examples, Dr. Stoddart is still of the opinion that they are cases of paraphrenia I hope he will renew his attack. After all, what is paraphrenia? It is only Magnan's "*délire chronique*" served up in a new form. Kraepelin admits as much with regard to paraphrenia systematica. I am, Sir, yours faithfully,

R. H. STEEN.

City of London Mental Hospital, near
Dartford, Kent, March 27th, 1920.

TUBERCULOSIS AND PENSIONS.

To the Editor of THE LANCET.

SIR,—The note in your last issue on the Diagnosis of Tuberculosis in Recruits and Pensioners by Dr. John Guy is timely. On looking through my records it is surprising to see how many men are getting expert at recounting symptoms which they think will lead to a diagnosis of tuberculosis, and which observation in a sanatorium entirely fails to confirm. Perhaps the most difficult are those who tell a history of hæmoptysis, though many give themselves away by their extravagant statements as to the amount and the circumstances.

To show how many are the cases of deliberate or subconscious malingering I have gone into my records here for the last six months, and find that the figures are sufficiently remarkable to bring before your notice. The cases are sent in by the county tuberculosis officers whenever the history or symptoms appear to indicate that careful clinical investigation may be required to settle the diagnosis. The concentration methods of examining the sputum in use at the county laboratories (under the control of Dr. S. Barwise, county medical officer of health) settle the diagnosis of some of them quite clearly by the finding of tubercle bacilli, even when in very small numbers. The "negative" cases are given exercise tests with rectal temperature controls, an X ray screen and plate examination is made, and in some cases an attempt is made to induce focal reactions with tuberculin where there are no contra-indications to such a method. The period of observation takes about ten days, and includes careful clinical examinations at different times of the chest.

What have been the results? Out of 103 cases in six months, 25 were "flagrant" cases of tuberculosis with positive sputum: 52 were very early and "closed" cases: and 26 were "non-tuberculous." That is, *one-quarter* of all the admissions of ex-soldiers were negative to all tests, or, as I prefer to put it, not suffering from active or recent tuberculosis. Now, on looking into the statements of these men with regard to their symptoms, one is struck by the fact that they seldom claim less and often more than the "sputum positive" case, shortness of breath and loss of voice being the most frequent symptoms. If kept in bed under close observation many of these cases get tired of the pretence and freely admit they are now quite well—within a week.

At a time when the financial resources of the country are strained to the utmost it is essential that money should not be frittered away in pensions to the undeserving, and, while it is conceded that the ex-soldier should have the benefit of any doubt that may exist, it is very important that all reasonable means to clear up such doubts should be taken. A few pounds spent on a proper diagnosis may save many hundred pounds in pension money, and many a man's self-respect may be restored by being firmly told that he has no claim to a pension. Hasty diagnosis on the lines of least resistance is more common and more expensive to the country in cases of suspected tuberculosis than in any other condition.

I am, Sir, yours faithfully,

W. C. FOWLER.

Derbyshire Sanatorium, Chesterfield, March 29th, 1920.

THE DRINKING OF METHYLATED SPIRITS.

To the Editor of THE LANCET.

SIR,—Partly on account of the increased cost of whisky, brandy, &c., and partly because the purchase of these spirits is restricted to a few hours during the day, the drinking of methylated spirits appears to be greatly on the increase. I have had under treatment recently several patients who have taken to methylated spirits when nothing better was obtainable, and there have been references to the practice in the daily press.

A simple method of making this beverage unpopular is to add tartar emetic, ½ gr. to each ounce, and to label the mixture "poison." I have for many years had this addition made to the methylated spirit used for household purposes in an institution with which I am connected, and I believe that the "poison" label has been sufficient to deter the inmates from sampling the stuff. The cost of the addition to all the methylated spirit sold to the public would not be heavy, say 1*d*. a gallon, and the cost of other additions such as shellac or naphtha would be saved, though to colour the mixture blue (which I have never done) might be an advantage.

I am, Sir, yours faithfully,

F. S. D. HOGG.

Rickmansworth, March 29th, 1920.

UNIVERSITY COLLEGE, LONDON: WAR MEMORIAL TO FALLEN STUDENTS.

To the Editor of THE LANCET.

SIR,—We trust you will give us the hospitality of your columns to call the attention of former student of University College and University College Hospita London, to the memorial we are endeavouring to rais to college and hospital men who fell in the war. Owin to the many changes that have taken place during an since the war, our address-list is not complete. It wi be of great assistance to us if all members of the Colleg who have not already received our appeal will sen post-cards with their names and addresses and dates c student years to the honorary secretary. We sha then be very glad to send them full particulars of ou war memorial scheme. We hope we may rely on th support of all students, past and present.

We are, Sir, yours faithfully,

GREGORY FOSTER,
Chairman.
G. BLACKER,
Vice-Chairman.
LAWRENCE SOLOMON,
Hon. Secretary.

University College, London, March 25th, 1920.

PAY IN THE INDIAN MEDICAL SERVICE.

To the Editor of THE LANCET.

SIR,—May I place before your readers interested in I.M.S. prospects the following facts showing the relatively deteriorated condition of the I.M.S. both in relation to their fellow military officers, and to the other scientific services in India.

Army Instruction India 321 of 1919 fixes a new scale of consolidated pay for I.M.S. officers, abolishes the station hospital allowances introduced in Indian Army Instruction 1343 of 1918, and continues in force the abolition of all previous allowances enumerated in the latter Indian Army Instruction—viz., additional charge allowances, horse allowances, and plurality of charges.

Indian Army Order No. 86 S fixes a new rate of grade pay for Indian Army regimental officers, but continues the old rates of staff allowances (vide table below)—viz, company officers, Rs 100 per mensem), company commander (Rs 200 per mensem), quartermaster (Rs 150 per mensem), adjutant (Rs 200 per mensem), second in command (Rs 250 per mensem), command (Rs 600 700 per mensem), and depot command (Rs 400 per mensem) This results in salaries far above the new rates of I M S salaries

This Indian Army Scale of Salaries of I A O 86 S was fixed for one specified reason only—viz, "high cost of living" The I M S new scale of salaries of A I I 321 was fixed for one specified reason only—viz, "to attract European candidates of the highest professional qualifications'

It will be observed from the appended table, for example, that the minimal salary of an Indian Army captain of nine years completed service exceeds the salary of an I M S captain of nine years completed service and this in spite of the I M S captain s supposed seniority *of* six years due *to* his previous professional training

Will *candidates of the type specified be attracted by* salaries below those of fellow military officers six years their juniors whose salaries are fixed to meet "the high cost of living ' The new scale of salaries of the Indian Forests and Public Works Engineers are on the annual incremental system, and are superior to the I M S salaries Starting with Rs 450 in the former and Rs 550 in the latter service, Rs 1000 is reached at the tenth and Rs 1500 at the twentieth year of service

I append a table showing the *relative position of the* I M S to the Indian Army The salaries are given in rupees per mensem

Rank and years of completed service	I M S	Indian Infantry *	Indian Cavalry	Supply and Transport †
	Consolidated + nil	Grade + Staff	Grade + Staff + Horse allowance	Grade + Staff
Lieut 7 yrs	550	475+ 100 or 150 200 250 550+ 400	475+ 100 or +60 150 200 250 550+ 400 +60	475+ 250 or 550+ 300
Captain 5 yrs 7 9 10	700 750 800 900	700+ 100 or 150 200 750+ 250 400	700+ 100 or +60 150 200 750+ 250 +70 400	700+ 300 or 750+ 400
Major 15 yrs 20	1000 1150	900+ 200 or 250 400 950+ 600	900+ 200 or +90 250 400 950+ 700 +90	900+ 400 or 500 950+ or 600
Lieut Colonel	1550	1150+600	1150+700+90	1150+800 or 1000

* *Vide current Indian Army Orders* and Indian Army Gazettes to see the enormous numbers of Captains and Lieutenants holding company command depot command and second *in command*

† Vide Indian Army *Quarters List to see grades of* Lieutenants Captains and Majors

Thus it will be seen *that the I M S salaries*, although consolidated, like the Forests and P W D, lack their steadily *progressive* scale Like the Indian Army, the I M S has long intervals without increments, but lacks its staff pay of progressively increasing amounts to make up for the fewness of increments of grade pay Thus the I M S salaries have the disadvantages of both and the advantages of neither, and are inferior *in amount* to either, although supposed to attract men *older* in years and with more *costly training'* *Let it* also be remembered that the six years seniority previously given to I M S officers no longer exists, owing to the Indian Army acceleration of promotion

I am, Sir, yours faithfully,
I M S

March 4th 1920

TAUNTON HOSPITAL—As a portion of the memorial to the late Lord St Audries the West Somerset Agricultural Memorial Fund Committee has raised £500 for the endowment of a bed in the Taunton and Somerset Hospital

Parliamentary Intelligence.

HOUSE OF COMMONS

WEDNESDAY, MARCH 24TH

Nurses' Registration Council

Mr **GRUNDY** asked the Minister of Health whether he could give an assurance that in *the appointment of the first* council under the Nurses Registration Act there would be included representatives directly nominated by bona fide nurses trade unions, as distinct from associations presumed to cater for nurses, but directed and controlled by persons other than nurses—Dr **ADDISON** replied Under the schedule to the Act I am bound to consult, and I have consulted three *organisations* specifically named and such *other associations or organised bodies of nurses or matrons as* ask to be consulted No organisation is given the right of direct nomination to the General Nursing Council The invitations in connexion with the membership of the Council will be issued to morrow

Deaths from Anæsthetics

Mr **GILBERT** asked the Minister of Health whether his attention had been *called to some recent* inquests held in London into deaths caused by the use of various anæsthetics, whether he had received any riders passed by the juries in these cases, whether he proposed to make any further inquiry into these cases and whether he proposed to introduce *legislation to provide that* anæsthetics should only be administered by properly qualified medical men—Dr **ADDISON** replied I am in communication with the Home Office, but am not at present in a position to make any statement with regard to the last part of the question

Health Services in London

Sir C **COBB** asked the Minister of Health whether he had received a report, *which was adopted by the London County* Council *on* Dec 19th, 1919, embodying a scheme for the better organisation of health services in London whether he was in general agreement with the proposals of the London County Council, and, in order that the County Council *might be in a position to develop its proposals in* greater *detail*, whether he was prepared to receive at an early date the deputation suggested by the Council—Dr **ADDISON** replied I have received the report to which my honourable friend refers, and it is being carefully considered, but as my *honourable* friend knows, it raises a number of *most* important and complicated questions and I think it would be of advantage both to the Council and the Government that these questions should be further examined before I receive the suggested deputation

Clothing for Tuberculous Patients

Mr **GWYNNE** asked the Pensions Minister whether a decision had yet been reached *in regard* to the better provision of special clothing and bedding for ex Service men suffering from tuberculosis, and, if so, what were the concessions—Sir J **CRAIG** (Parliamentary Secretary *to the* Ministry of Pensions) replied Under the present regulations of the Ministry underclothing and *great* coats are provided on *loan for* the use of men in sanatorium and other institutions, and great coats for the use, where necessary, of men under out patient treatment at home Extra blankets are also provided by local committees *for men suffering* from tuberculosis *who* are *under* open air treatment at home, and *for* whom such extra blankets are *certified to* be necessary The arrangements under which these articles are provided appear to be working satisfactorily, but *if my* honourable friend has information to *the contrary* my right honourable friend will *be* glad to consider it

Indian Medical Practitioners in British East Africa

Mr **WATERSON** asked the Under Secretary of State for the *Colonies* whether Indian medical practitioners in British East Africa were forbidden to carry on independent medical practice, and, if so, on what grounds—Lieutenant Colonel **AMERY** replied *The question of* medical practice in the East Africa Protectorate is governed by the Medical Practitioners' and Dentists' Ordinance, 1910 Under that Ordinance the holder of any British Indian degree diploma *or licence* entitling him to registration in the United Kingdom is entitled *to be registered* as a medical practitioner in the East Africa Protectorate Under the same Ordinance the practice of systems of therapeutics according to native Indian or other Asiatic *method is permitted for* persons recognised by the *community* to which they belong to be *duly trained* in such practice, subject to provisos that such systems may only be practised amongst the community to which the practitioner belongs, and that *no* Act under any such system on *the part of such* persons as is dangerous to life shall be permitted

National Health Insurance Bill Expenses.

The money resolution in connexion with the new National Health Insurance Bill, which had passed through Committee, was reported to the House and agreed to.

THURSDAY, MARCH 25TH.

Sanatoriums for Uncertifiable Mental Cases.

Sir A. SHIRLEY BENN asked the Pensions Minister if he would state how many sanatoriums were provided by his Department for the benefit of uncertifiable border-line cases of loss of mental balance occurring among ex-soldiers as distinguished from neurasthenics of a pseudo-paralytic type, where they were situated, what accommodation they furnished, and were facilities afforded for interesting occupations for the purpose of promoting an early return to the conditions of industrial life.—Sir J. CRAIG replied: Eighteen institutions, providing 2046 beds, have been set up by the Ministry to deal with the cases described. They are situated at Edinburgh, Shotley Bridge, Leeds (2), Altrincham, Woolton, Stockport, Leicester, Maidenhead, Bath, Exeter, Orpington, Tooting, Denmark Hill, Roehampton, Chepstow, Craigend, and Leopardstown. Further institutions are in course of preparation. Occupational training has been provided at the majority of these homes, and at the remainder is being instituted as rapidly as possible. Accommodation in the treatment and training centres will also be available for the convalescent cases which still require treatment and training. There are, in addition, clinics at Lancaster Gate, Manchester, and elsewhere where out-patient treatment is given for the milder type of neurasthenic, such as the pseudo-paralytic type.

Mr. WATERSON asked the Minister of Health if it was his intention to start sanatoriums for early uncertifiable mental cases which did not at first involve detention; and, if so, could he state the approximate cost of such outlay.—Dr. ADDISON replied: I am afraid I cannot add anything to the answer which I gave on March 12th, in which I explained that any such scheme would require legislation, and I am not in a position to say when such legislation will be introduced.

Sanatorium Benefit under the Insurance Act.

Lieutenant-Commander KENWORTHY asked the Minister of Health if he would state to whom and in what manner it was proposed to transfer the duty of providing sanatorium benefit to insured persons, hitherto performed by the Insurance Committees, under the provisions of the new National Health Insurance Bill.—Dr. ADDISON replied: Institutional treatment for insured persons suffering from tuberculosis is already being provided in most areas by the public health authorities under agreements made with the Insurance Committees, and it is proposed to transfer the duty of providing such treatment to appropriate public health authorities. I am hoping to introduce legislation for this purpose at an early date. Domiciliary treatment for insured persons suffering from tuberculosis will be provided by Insurance Committees under Clause 4 (3) of the National Health Insurance Bill as part of medical benefit.

MONDAY, MARCH 29TH.

Medical Benefit Regulations for Scotland.

Major HENDERSON asked the Secretary for Scotland whether he was aware that English medical panel practitioners had already received copies of the Medical Benefit Regulations for 1920, whereas Scottish medical panel practitioners had been unable to obtain the regulations, although they had applied for them; and whether, under these circumstances, he would take steps to have the regulations published and circulated to the medical profession without further delay.—Mr. MUNRO replied: The answer to the first part of the question is in the affirmative. I understand, however, that proofs of the regulations were issued to Panel Committees in Scotland on Jan. 19th. The Scottish Regulations cannot be finally issued until suggestions for amendment made by the doctors have been adjusted in consultation with the Scottish Committee of the British Medical Association. A meeting on the subject takes place to-morrow, after which the regulations will be issued as speedily as possible.

TUESDAY, MARCH 30TH.

Medical Referees and Industrial Fitness.

Mr. DUNCAN GRAHAM asked the Parliamentary Secretary to the Pensions Ministry whether he was aware that discharged soldiers who had been wounded or who had contracted disease during their service in the army, and were consequently unfit to resume their former occupations, were being certified by medical boards in the industrial districts of Scotland as being fit for light employment, which form of employment was being withheld from them either because of the inability or unwillingness of the employers to provide it; was he aware that many of the decisions of the medical boards were opposed to the opinions held by the panel doctors regarding the fitness of the men affected for work; and whether he would agree to set up a tribunal, composed exclusively of Members of the House, whose functions should be to determine the question of whether the views held by the panel doctors or the medical board accurately described the men's condition.—Sir J. CRAIG replied: The honourable Member is presumably referring to medical referees, as medical boards do not certify fitness for work. It is contrary to instructions for a medical referee to certify any man as "fit for light employment," and whenever a case of this kind is brought to notice the attention of the medical referee at fault is drawn to it. My right honourable friend does not think it necessary to set up a tribunal such as is suggested in the last part of the question.

Medical News.

BRITISH EMPIRE HONOURS.—Among the very numerous appointments to the civil division of the Order of the British Empire for services in connexion with the war are the names of four medical men to be Knights-Commanders, namely: Dr. Isaac Bayley Balfour, professor of botany in the University of Edinburgh; Major James William Beeman Hodsdon, F.R.C.S.Edin., member of Medical Advisory Board to the late Ministry of National Service; Lieutenant-Colonel David Wallace, F.R.C.S., Red Cross Commissioner and Military Inspection Officer, Auxiliary Hospitals; and Colonel Arthur L. A. Webb, Director-General of Medical Services at the Ministry of Pensions. Knighthoods have also been given to Professor William Henry Bragg, Quain professor of physics in the University of London; to Mr. Sidney Frederic Harmer, F.R.S., director of the Natural History Museum; and to Mr. Frederick J. Willis, assistant secretary to the Ministry of Health. The names of Commanders and Officers are unavoidably postponed to a later issue.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—An ordinary Comitia of the College was held on March 29th, Sir Norman Moore, the President, being in the chair. After the minutes of the meeting of the Censors' Board and of the previous meeting of the Comitia had been read, the President delivered the annual address, in which he reviewed the honours conferred upon the Fellows, Members, and licentiates during the last 12 months. He also announced that the College list contained the names of 357 Fellows, 506 Members, 13,800 licentiates, 1 extra-licentiate, 863 diplomates in public health, and 18 tropical diplomates. Eloquent obituary notices were then given of the 11 Fellows who have died during the year—viz., Dr. F. J. Smith, Dr. Joseph Wiglesworth, Dr. G. Bernard Brodie, Dr. E. G. Fearnsides, Professor W. S. Greenfield, Dr. C. A. Mercier, Dr. Guthrie Rankin, Sir William Osler, Dr. Laurence Humphry, Sir James Alexander Grant, K.C.M.G., and Dr. Samuel H. West.—The President then vacated the chair, and the election to the office of President for the ensuing year was held, Sir Norman Moore being re-elected. He then gave his faith to the College.—Licences to practise physic were granted to George Cleverdon Hartley, Birmingham University, and to Kathleen Suzanne Vine, Royal Free Hospital.—After returning thanks to the College the President declared the Comitia closed.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At examinations recently held the following candidates were successful:—

THIRD EXAMINATION FOR DEGREE OF BACHELOR OF MEDICINE.

Materia Medica, Pharmacology, and Pharmacy; Public Health; Medical Jurisprudence; Pathology and Elementary Bacteriology.—Francis Joseph Benjamin, John James Norman Daniels, Dorothy Esther Elliott, Roland Hewitson, Joseph Jackson, Morris Mickler, Lionel Myers (second-class honours), Joan Winifred Nicoll, Robert John Perring, Sydney Terry Pybus, Mary Foster Richardson, Olive Constance Wilson, and Philomena Ryland Whitaker.

UNIVERSITY OF ABERDEEN.—At the graduation ceremony on March 24th the following degrees were conferred:—

DOCTOR OF LAWS (LL.D.).

Sir Jagadis Chandra Bose, C.S.I., C.I.E., Founder and Director, Bose Research Institute, Calcutta (in absentia); Dr. William Bulloch, Professor of Bacteriology, University of London; Sir Robert Jones, K.B.E., C.B., Surgeon in Liverpool, late Major-General, A.M.S., and Inspector of Military Orthopædics; and Dr. David Nicolson, C.B., Lord Chancellor's Visitor in Lunacy since 1896, Medical Adviser of the Home Secretary in Criminal Mental Cases (in absentia).

DOCTOR OF MEDICINE (M.D.).

Alistair Sim Garden, James Leask, and Helen Lillie.

BACHELOR OF MEDICINE (M.B.) AND BACHELOR OF SURGERY (CH.B.).

Dorothy Edith Bryant, Alexander Victor Reid Don, Murray Young Garden* (second-class honours), Charles Albert Hay, Dorothy Mildred Holmes, Alice Mabel Lee Innes, Robert Cran MacLennan, Joseph Mackenzie Stuart, Douglas Mackenzie Thomson, and Ida Elizabeth Wood.

* Passed Final Medical Professional Examination with much distinction.

DIPLOMA IN PUBLIC HEALTH

Alfred George Brown Duncan Richard Ramsay Garden Evan Alexander Mackenzie Lachlan Martin Victor Mitchell (with credit) and Anne Simpson

BRITISH MEDICAL ASSOCIATION SCHOLARSHIPS AND GRANTS IN AID OF SCIENTIFIC RESEARCH —The Council of the British Medical Association is prepared to receive applications for research scholarships as follows 1 An Ernest Hart Memorial Scholarship, of the value of £200 per annum, for the study of some subject in the department of State Medicine 2 Three Research Scholarships, each of the value of £150 per annum, for research into some subject relating to the causation, prevention, or treatment of disease Each scholarship is tenable for one year, commencing on Oct 1st, 1920 A scholar may be reappointed for not more than two additional terms

Grants —The Council of the British Medical Association is also prepared to receive applications for grants for the assistance of research into the causation treatment, or prevention of disease Preference will be given, other things being equal, to members of the medical profession and to applicants who propose as subjects of investigation problems directly related to practical medicine

The conditions of the award of scholarships and grants are stated in the regulations, a copy of which will be supplied on application to the medical secretary of the Association

All applications, both for scholarships and for grants for the year 1920 21, must be made not later than Saturday, May 29th, 1920, in the prescribed form, a copy of which will be supplied by the medical secretary on application Each application should be accompanied by testimonials, including a recommendation from the head of the laboratory, if any, in which the applicant proposes to work, setting out the fitness of the candidate to conduct such work, and the probable value of the work to be undertaken This is not intended, however, to prevent applications for grants in aid of work which need not be performed in a recognised laboratory Applications should be made to Dr Cox, medical secretary of the Association, at 429, Strand, London, W C 2

NATIONAL COUNCIL FOR COMBATING VENEREAL DISEASES —A meeting of the Council was held on March 29th at the Royal Society of Medicine, Lord Sydenham presiding Lord Gorell (chairman of the Parliamentary Committee), Sir Malcolm Morris, Mr E B Turner, Mrs Torrey, Mrs Gotto (general secretary), and Dr Douglas White (honorary medical secretary) were present, but the general attendance was small Lord Sydenham referred to the controversy on self disinfection, and regretted that the efforts which he had made to bring about a round table conference between the National Council and the Society for the Prevention of Venereal Disease had proved unsuccessful A section of the public, realising that there was a lack of agreement between these two bodies, might, he feared, be inclined to ignore the activities of both. For himself, he did not believe in the possibility of so organising methods of self disinfection as to render their adoption of value to the civilian community The use of prophylactic packets would, he trusted, never be advocated by the Council Lord Sydenham laid stress on the necessity of securing for sailors the same preventive and curative facilities as are available for landsmen Speaking of the work of the International Red Cross at Geneva, he informed his audience of the official recognition of the N C C V D by that body In concluding he gave an impressive and sympathetic eulogium on the late Sir Robert Morant The greater part of the meeting was given up to a discussion on compulsory notification The importance of the subject was indicated by the chairman's statement that 40 per cent of patients were believed to discontinue treatment for venereal disease before finishing the course Strong views were enunciated on both sides Sir Malcolm Morris, whilst recording his belief that the time was coming when notification would be enforced, thought that much educational and propaganda work remained to be done to enable the public mind to assimilate and approve of the measure Evidently a majority of those present favoured the introduction of some form of compulsion.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Thursday, April 8th.

OBSTETRICS AND GYNÆCOLOGY (Hon. Secretaries—J. S. Fairbairn, Herbert Williamson): at 8 p.m.

Specimens:

Mr. T. G. Stevens: A Third Specimen of Douche-nozzle removed from the Female Bladder.

Mr. J. D. Barris: Cystic Embryoma of Ovary.

Dr. Eardley Holland: (1) A Placenta from a Combined Cast of Placenta-prævia and Accidental Hæmorrhage; (2) A Puerperal Uterus containing an Infected Fibromyoma.

Short Communications:

Dr. Williamson and Dr. Brockman: Two Specimens showing Extensive Fatty Change in Fibromyomata.

Lady Barrett: A Case with High Ammonia Coefficient.

Dr. Williamson: A Note on the Value of Blood-transfusion before Operation in Severe Secondary Anæmia.

Dr. A. C. Palmer; Two Cases of Rupture of the Vagina during Labour (with Specimens and Epidiascope Demonstration by Dr. Holland).

Mr. T. G. Stevens: A Case of Sacculation of Gravid Bicornuate Uterus.

Friday, April 9th.

ANÆSTHETICS (Hon. Secretaries—R. E. Apperly, Ashley S. Daly): at 8.15 p.m.

Annual General Meeting—Election of Officers and Council for 1920–1921.

Discussion (at 8.30 p.m.):

On "Anæsthesia in Operations on the Thyroid Gland," opened by Mrs. Dickinson Berry.

CLINICAL.—No meeting of this Section will be held on April 9th. The next meeting will be held on Friday, April 16th, at 5.30 p.m. (Cases at 5 p.m.) Those wishing to exhibit cases are requested to communicate with the Hon. Secretaries.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

Tuesday, *April 6th.—10 a.m., Dr. McDougal: Electrical Department.* 2. p.m., Dr. Pernet: Skin Diseases.

Wednesday.—10 a.m., Dr. A. Saunders: Medical Diseases of Children. 2 p.m., Mr. Gibb: Eye Disease.

Thursday.—2 p.m., Dr. G. Stewart: Nerve Disease. Mr. B. Harman: Eye Department.

Friday.—2 p.m., Dr. Morton: X Rays. Mr. Banks Davis: Diseases of the Throat, Nose and Ear.

Saturday.—2 p.m., Medical Cases.

Daily:—10 a.m., Ward Visits. 2 p.m., In-patient and Out-patient Clinics and Operations. Out-patient Department closed from April 1st to April 6th.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL (University of London).

A Course of Post-Graduate Lectures on Syphilis is being given by various members of the staff of King's College Hospital during the present year.

Friday, April 9th.—9.15 p.m., Sir StClair Thomson: Syphilis of the Throat, Larynx, &c.

UNIVERSITY OF SHEFFIELD—FACULTY OF MEDICINE POST-GRADUATE LECTURES, at the Sheffield University Pathological Museum.

Wednesday, April 7th.—4 p.m., Prof. Connell: Pathology of Bone Disease.

SALFORD ROYAL HOSPITAL and ANCOATS HOSPITAL POST-GRADUATE DEMONSTRATIONS, at the two Hospitals alternately.

Thursday, April 8th.—4.30 p.m., Dr. Sturrock: Epilepsy. (At Salford Royal Hospital.)

BRIGHTON DIVISION OF THE BRITISH MEDICAL ASSOCIATION, at the Children's Hospital.

Thursday, April 8th.—4 p.m., Clinical Demonstration.

POULTRY FARMING
AN OCCUPATION SUITABLE FOR CONSUMPTIVES

BY P C VARRIER JONES, M A CAMB ,
M R C S , L R C P LOND ,
HONORARY MEDICAL OFFICER PAPWORTH COLONY CAMBRIDGE

AND

SIR G SIMS WOODHEAD, K B E , V D , M D , LL D ,
PROFESSOR OF PATHOLOGY, UNIVERSITY OF CAMBRIDGE FELLOW
OF TRINITY HALL CAMBRIDGE

Poultry farming, to be at all successful, requires a full knowledge of the subject Such knowledge can only be acquired by careful and well directed practical experience No short course of training, such as that recommended and arranged by the Ministry of Pensions, is going to be of the slightest use; indeed, it cannot but be harmful Consumptive patients too often start poultry keeping with the idea that after the main work of the day is done, they will be able to attend to the few chickens that are to increase their weekly earnings In general a consumptive cannot manage a full day's work in the competitive business world Still less can he manage his chickens as a supplementary industry The inevitable result is that both the business and the chickens go to the wall. It is equally certain that the returns on a capital of, say, £100, will be out of all proportion to the time and energy which must be spent in carrying on a small farm How is the patient to obtain adequate housing and the ample food and clothing so necessary for his welfare? In bad health to begin with, and subject to frequent relapses at the most critical time of the year, the patient cannot look after his chickens unaided, and it is small wonder that the small farm is soon given up If the work is taken up on a larger scale, larger capital is required, and for the first year, even with the hardest work, there can be no income The energy, long hours, and constant care required for the building up of such a farm must, in most cases, be out of the question so far as the average consumptive is concerned

As a rule, the ex soldier has not the necessary capital to finance the business, much less the necessary money to pay wages for the help he undoubtedly requires The one man business, so far as the consumptive is concerned, is undesirable Help must be available the instant a relapse, however slight, occurs

An Industry, not a Charitable Concern

There remains, then, for consideration the employment of a consumptive as an employee on one of the many egg farms which are scattered all over the country These, it must be remembered, are run, as all businesses are run, for profit Any given farm can "carry" only a certain number of employees, and there is no room for a man whose labour is not a source of profit to the employer or company, as the case may be The hours of work are long, and these hours must be worked seven days a week It is a matter of considerable difficulty to induce the management of a poultry farm to allow one of the staff to work fewer hours per week than the others, and without the concession of this privilege the career of the consumptive as an employee on such a farm quickly comes to an end

In whatever trades inquiries are made the same problem presents itself Whether in an out door employment or an indoor one in a factory it is the pace that kills the consumptive, or, in other words, the competition with the healthy worker A permanently damaged man cannot keep pace with the healthy competitor, and this holds good whether the work be indoors or out Consumptives only keep well in an environment in which great attention is paid to certain factors—working hours regulated to their strength, absence of competition with healthy workers, an abundant dietary, and ample opportunity to recuperate when a slight relapse occurs, and lastly, but by no means least, ever ready help at hand should adverse circumstances be encountered

The most important question when industries suitable for consumptives are under consideration is whether these essentials can be provided and at the same time the industry be made a business in the sense of not being purely a charitable concern It can be done, but it can only be done by the study of the particular industry, and with the help of a man who thoroughly understands not only the industry in question but also the physical and temperamental peculiarities of the consumptive patient

The Poultry Farm at the Papworth Colony

A brief account of the building up of the 40 acre poultry-farm at the Papworth Colony may assist others to build an even better one, and thus help in solving the problem of the employment of the consumptive In the first place, the labour of the healthy individual must not be called upon It is the fashion to start a colony with healthy labour, to prepare the way and create elaborate buildings for the reception of the industries, and, when these are complete, to draft the patients in for training Such a procedure cuts at the very root of successful business building All must realise that unless interest in the industry is aroused an enormous incentive to work is lost We wish the patient to realise that he is building up a business, not running an institution We find that to the consumptive no influence is more depressing or deadening than the absence of any chance of promotion and the attainment of a better position The joy of life must be conserved at all costs The difference between monotony of training in a fully equipped establishment and pride of helping in the development of a business is just the difference between being a unit in a training scheme pure and simple and an apprentice in a live business concern

We have endeavoured, therefore, and have so far succeeded, in employing only consumptive labour to build up and carry on our poultry farm, exactly as if it were a private commercial enterprise The men employed in this task look forward to permanent employment on the farm, or when this is impossible, to being started on a subsidiary farm under the wing of the central organisation Beyond this, however, we have learned that it is possible to pay these men a definite wage according to their working capacity, and to pay this wage out of the profits of the farm This is rather a remarkable outcome of our experience, for rarely is a pupil on a poultry farm paid anything for his labour The explanation is that in a commercial egg farm a profit had to be made and paid out in dividends to the owners or shareholders At the colony this profit is divided amongst the workers on the farm, and only by a specially arranged method of working can this be done Obviously, therefore while the commercial plant is placed at a disadvantage when it attempts to employ consumptive labour, when the Papworth Poultry Farm can be run by consumptives entirely for consumptives

How to Meet the Consumptive's Special Difficulties

One of the great difficulties in the way of a consumptive running a small business is the risk of a relapse at a critical time in the career of that business For instance all through the hatching season—especially if artificial methods are employed—a short spell of illness on the part of the owner may seriously prejudice, if it does not permanently injure, the future development of the concern For a consumptive to be shielded and carried over these periods of indisposition in such a way that his business may not suffer, he must have help quickly and cheaply When a consumptive is set up in business on his own account this can best be arranged by some method of affiliation with a business similar to his own from which he may obtain almost instant assistance A large poultry farm like that at Papworth is in a position to provide this help, and so confer an inestimable boon on the man in question For those who are permanently employed on the farm the work is so arranged that relays of workers can be set to do various jobs, to which their strength is equal In other words, a system of repetition work is introduced which economises labour in the long run, and more hands can be employed per acre than under any other system The profits are available for this extra labour, it is possible to pay good rates of remuneration, and general satisfaction is secured It is only by carrying on the enterprise on a large scale that this dilution of labour is possible, and it is certainly only by this method that the additional labour is profitable and available for outside help Indeed, in any scheme for the employment of the consumptive it must be borne in mind that the industry selected must be one which can take a satisfactory number per acre, and which allows of transference of labour to the area in which it may temporarily be required

For many reasons, then, these poultry farms must be more or less centralised Poultry farming is one of the trades that require a larger acreage than many others—for example, cabinet making An acre of workshop space can, of course, accommodate a far greater number of hands than can a poultry farm On the other hand, a poultry farm can carry many more hands than a general farm, moreover, it is possible to arrange the work on the repetition system more easily and to arrange the hours accordingly It has been demonstrated that a poultry farm built up, equipped, and run by consumptives for consumptives, can be made a paying concern; that it can be made capable of employing a large number of hands, and that this is done not by turning the profits into dividends but by paying them out in wages for the extra hands which could be dispensed with if normal labour were employed. This, it seems to us, is the proper method of attacking the great problem of the employment of consumptives. By attacking it on these lines it should no longer be necessary to court failure by applying to charitably disposed individuals to take into employment on their farms consumptives unable to give a full day's work or work every day in the week. A practical method of employing the consumptive has been evolved and a sound business has been provided for the purpose of employing consumptives and, most important of all, of working them at their own pace.

The question of industries for consumptives is one of pressing importance. The waste of human material caused directly by the tubercle bacillus calls for immediate attention. The figures setting forth the loss to the nation are well known. By a careful study of each suitable industry on the lines set out above it will be possible, we believe, to save much of this waste, to economise labour, promote the welfare of the consumptive, and add to the protection of the country. What about the waste of human material? Has it been so salvaged and used to the best advantage that waste is eliminated or reduced to a minimum? In the past I think not. Of all our resources labour has received the least consideration, granting exceptions in isolated cases. After the cream of a man's efforts had been extracted he was thrown on the scrap-heap, and in many cases his best assets were lost, not only to himself, but to the State. We are at length waking up to the fact that this material can be usefully employed, but the conditions of employment under which it can be made profitable to the State are only now being worked out and the lines of future action indicated.

DEFECTS OF HEARING AND VISION IN THE SCHOOL CHILD.

In a lecture on medical inspection in schools given under the auspices of the London County Council at the London Day Training College, Southampton-row, London, W.C., on March 24th, Dr. F. S. Langmead emphasised the importance of the proper treatment of middle-ear disease in school children. Statistics showed that at the school-leaving age 8·9 per cent. of the children had less than three-quarters of the normal hearing and 6·4 per cent. less than half the normal. The chief causes of the disease were infections from the throat, tonsils, and adenoids, and, more remotely, the infectious diseases. A few, though not many, cases were due to tuberculosis. The condition was an extremely important and dangerous one, often followed by mastoid disease, meningitis, thrombosis, and septicæmia.

Dealing with vision, the lecturer said the figures for London showed that upwards of 20 per cent. of boys and 22 per cent. of girls had defective vision. In Staffordshire the statistics gave 26·7 per cent. boys and 33·1 per cent. girls. Among older children just about to leave school Dr. C. J. Thomas had found that 10 per cent. had very serious defects of the sight, while 13 per cent. had less serious defects. Generally speaking, the defects in school children occurred before the child entered school life, but eye defects were often school produced. If eye defects existed school life might make them worse, and even lead to total blindness or such further incapacity that education was wasted and the wage-earning capacity considerably diminished or lost. Errors of refraction were the most common, and of 755 children examined for eye defects 650, or 86 per cent., suffered from hypermetropia. This trouble not only caused the child great inconvenience, but might give rise also to headache, vomiting, nausea, want of appetite, giddiness, and eventually end in a condition of neurasthenia. Even fits had been ascribed to eye-strain. Myopia was an even more serious condition, and of the 755 children examined 105, or 13·9 per cent., had myopia. While the only symptoms complained of might be indistinct vision, secondary destructive changes might take place, detachment of the retina being one of the most severe. There seemed to be some individual predisposition to myopia, which was considerably increased if the eyes were used for near work. Probably, for this reason, it was more common in cities. Myopia was commoner in secondary schools, where finer work was done, than in primary, and among the professional classes. Some years ago Priestley Smith found that while there were 5 or 6 per cent. of myopes in elementary schools the percentage among teachers in the training colleges was no less than 20. The defect was commoner in girls, but that fact had not been explained. It was interesting to note that south of the river Thames the children came out best with respect to nutrition, teeth, and vision; north of the river nutrition and teeth were worse, but the vision was about the same. In the East of London the nutrition and teeth were the best of all, but the vision the worst, the explanation being probably the large alien population with a predisposition to myopia. Astigmatism was a third variety of refractive error giving rise to symptoms of eyestrain which might be even more severe than in hypermetropia. In the prevention of these defects much might be done by attention to proper lighting in schools and the provision of suitable desks.

In conclusion, Dr. Langmead called attention to an educational circular which permitted teachers to give to certain children "easy" instruction and "oral" instruction only. While these instructions did not seem to be fully known, he pointed out that unless they were intelligently acted upon there was danger of making a child blind by forcing him to attend school.

RESCISSION OF RATS ORDERS.

In view of the Rats and Mice (Destruction) Act, 1919, which came into force on Jan. 1st, the Food Controller has revoked the Rats Order, 1918 (amended in 1919). The Orders of the late Local Government Board—viz., the Local Authorities (Food Control) Orders (No. 5), 1918, and (No. 1), 1919, empowering local authorities to enforce and execute the Rats Orders, have consequently lapsed. The Ministry has thought it desirable, however, in order to avoid any possibility of confusion in the matter, that the Orders of the Local Government Board should be formally revoked, and copies of the rescinding Order have now been enclosed for the information of the local authority. A joint memorandum on the arrangements to be made by local authorities for the destruction of rats and sparrows was issued in April, 1917, jointly by the Local Government Board and the Board of Agriculture. The Rats and Mice (Destruction) Act, 1919, has also become obsolete and is formally withdrawn.

A USEFUL MEDICAL INDUCTION COIL.

The "physio" faradic wave apparatus is a medical induction coil which embodies many features of practical utility. The interrupter is of the type originally introduced by Tripier, and it can be regulated to vibrate any number of times between 60 and 3000 per minute. The secondary coil is composed of four separate windings, and, by means of a switch, the current induced in either of these can be utilised. Currents at different voltage can thus be obtained. These can be finely varied by sliding the secondary coil over the primary. The secondary coil is mounted on two parallel metal runners, thus allowing its easy movement to and fro, so that an even rhythmic variation of the strength of the induced current can be readily obtained. The coil is mounted in a neat case to which is fitted a leather strap by means of which it can be carried about and two dry cells for operating are packed in the base of the case. The well-made apparatus is manufactured by the Medical Supply Association, Gray's Inn-road, W.C.

SCHOOL ATTENDANCE: AN UNUSUAL CASE.

At Tavistock (Devon) recently a local builder was summoned for not sending his male child to school. It was stated that the reason of the non-attendance was that the father did not wish to allow the school medical officer to take a specimen of the child's hair for microscopical examination for ringworm spores. The medical officer had found these on a previous examination. For the defence it was contended that two medical practitioners had stated the boy was free from ringworm, and had written to that effect. Eventually the father stated that he would allow the school medical officer to examine the hair, and the case was then withdrawn.

POST-MORTEM EXAMINATIONS AND INQUESTS.

Dr. F. J. Waldo states in his latest report that in 85 per cent. of the inquests before him in 1918 he ordered post-mortem examinations to be held. This is a high proportion, but it is not in any way too high, and, indeed, there must be very few cases, an inquest being necessary, where a post-mortem examination can safely be dispensed with. A good example of the usefulness of a post-mortem examination was afforded at a recent inquest held by Mr. A. D. Cowburn, deputy coroner for North-East London. The deceased, a man, 65 years of age, was found lying dead on the pavement outside his house, having apparently thrown himself from an upstairs window. On the first appearances it was a case of suicide. Post-mortem examination, however, showed such extensive disease of the heart that the medical evidence ascribed death to this and not to the fall. The medical witness suggested, on a matter which, in the absence of any other evidence, was conjecture only, that the deceased had gone to the window and opened it on finding a sudden difficulty in breathing. That he should fall forward in dying, and overbalancing should fall out through the window, would be the natural consequence of this. The jury adopted the view put forward by the medical man, and returned a verdict of accidental death upon the information supplied by post-mortem examination.

The ex-Service men of Messrs. W. D. and H. O. Wills, of Bristol, have collected £500 for the Bristol Children's Hospital.

Considerations
ON
ABDOMINAL EMERGENCIES
IN WHICH OPERATIVE INTERFERENCE IS *EITHER CONTRA-INDICATED OR* RESTRICTED.

By CHARLES F. M. SAINT, C.B.E., M.S., F.R.C.S.,

PROFESSOR OF SURGERY, UNIVERSITY OF CAPE TOWN, LATE HONORARY SURGEON, HOSPITAL FOR SICK CHILDREN, AND SURGICAL REGISTRAR, ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE

Abdominal emergencies naturally fall into two categories, those requiring operative interference, and those in which such interference is not necessary. The operative interference may be judged an immediate necessity, or its postponement be considered advisable. The measures that should be adopted may be either radical or partial and palliative. It is well recognised that the operative part of emergency surgery ranks high in point of ease, and this very fact emphasises the paramount importance of judgment in this class of work; in other words, here the science of surgery outweighs the art. The surgeon's course of action depends on his survey of the case, and that should depend upon his diagnosis. It therefore follows that correct diagnosis is of prime importance, and the more exact and detailed it is the sounder must be the judgment and plan of action, the more complete will be the classification of the cases, and the greater the proportion not requiring operation. It is the easier, and at present more popular, course to operate, but this inevitably leads to a number of unnecessary abdominal operations. Nothing is more demoralising than to open an abdomen without discovering any pathological process, and no surgical progress can be expected if indiscriminate operating becomes the rule.

There are a few points which arise out of the above considerations, and which are worthy of note. A case left without operation, when against the opinion of others, is attended with much worry and a sense of greatly increased responsibility, and these are intensified by the latitude that such a course offers for difference of opinion. Further, should recovery occur, the diagnosis may remain uncertain.

Again, adequate stress must be laid upon the fact that, in a certain class of case, the surgeon's attitude will be controlled by the circumstance whether the patient is in hospital under his direct supervision or not. One may say, without hesitation, that the majority of cases are straightforward, and the certainty of the diagnosis is, for all practical purposes, unquestionable. There remains, however, a minority in which the diagnosis is difficult and uncertain, and in many of these the attitude of masterly inactivity is only justifiable if the patient be placed in such circumstances that an operation may be performed immediately if the necessity for it develops. Should these circumstances not be available, there may be no alternative to an exploratory operation.

In the following cases, from among the abdominal emergencies recently under the care of the writer in the Royal Victoria Infirmary, Newcastle-upon-Tyne, and in a private hospital, this last point must be kept prominently in remembrance.

Cases of Acute Appendicitis.

Case 1.—The patient, A. B., was a small, plump girl of 14. She was admitted to hospital 3/10/19 suffering from an acute attack of abdominal pain of 48 hours' duration. Only a week previously she had been discharged from a sanatorium, where she had been under treatment for pulmonary tuberculosis during the past 18 months. She gave a typical history of being seized with abdominal pain, which was at first felt all over the abdomen, and which later settled in the right iliac fossa. She vomited two or three times during the first day, but not afterwards. There was no trouble with micturition, and there had been no diarrhœa. She had had no previous attack.

On admission, 48 hours after the commencement of the attack, she was flushed, and her tongue was moist and thickly coated with brown fur. Her general condition appeared to be good, and there was an abundance of subcutaneous fat, apparently the result of her sanatorium treatment. Her chest showed marked bronchitis, as evidenced by coarse râles, frequent coughing, and the expectoration of copious muco-pus. Temperature 103·8° F., pulse 120. Locally there was marked tenderness and rigidity, limited to the right iliac fossa, and a feeling of an indefinite mass in the same region, as of adherent omentum. On account of the condition of the chest it was decided to wait. Should the condition of the patient, either general or local, become worse operation would be performed by rectal or local anæsthesia, but should it improve no operative measure would be undertaken. In four hours the temperature had fallen to 102° and the pulse to 112, and by the next morning the temperature was 98·8° and the pulse 108. Subsequently two evening rises to 100·6° and 100·4° occurred, but the general condition and the local signs steadily improved, and by the end of a week her attack had entirely subsided and she was discharged from hospital well, except for her chest.

Case 2.—The patient, C. D., a clerk of 20 years of age, was admitted to hospital 16/8/19 with an attack of abdominal pain of 24 hours' duration, vomiting, and temperature. The attack commenced on the evening before the night of admission, when she was seized with sudden pain across the abdomen rapidly becoming localised in the right iliac fossa. The pain was accompanied by a great deal of vomiting. Apart from one similar attack 12 months previously, when she was about a fortnight in bed, she had always been well. On examination she was a well-nourished, robust looking girl, her tongue was covered with a moist brown fur, and the breath somewhat fœtid. Temperature 99·8° F., pulse 86. Locally there was no distension of the abdomen. There was marked rigidity and tenderness, limited to the right iliac fossa, but no mass was felt, deep palpation being resisted. Diagnosis of acute appendicitis, with stricture, not perforated.

Operation.—The usual oblique incision was made in the right iliac fossa, and the abdomen opened. There was generalised tuberculous peritonitis, with numerous adhesions and miliary tubercles on all the gut examined. In addition there were many tuberculous mesenteric glands, most marked in the ileo-colic angle, and the wall of the cæcum showed extensive tuberculous disease. The appendix was found on the inner side of the cæcum; it was acutely inflamed and rigid, being like the small "erect penis," which has been described. There was an enlarged gland in its mesentery. It arose from the cæcum just at the site of reflection of the peritoneum on to the iliac fossa. The advisability of removing the appendix was by no means an easy problem. It could have been removed easily, but it was quite certain that part of the cæcal wall which would be employed in the process of inversion of the stump would be uncovered by peritoneum, and, further, the tuberculous condition of the cæcum would necessitate a very large inversion, if it proved feasible at all. Hence the probability of a fæcal fistula resulting, or, at the worst, a septic infection of the peritoneum in addition to the tuberculous one already present, was

No. 5041

very likely event. The idea of removing the tuberculous cæcum with the appendix, either by a limited operation or a complete removal of the gut in the ileocolic and right colic distribution, was not entertained on account of the diffuse tuberculous peritonitis. Further, the appendix showed no external sign of gangrene or of impending perforation. In consequence, it was decided to leave the appendix in situ and await developments, since, if the inflammation terminated in gangrene and perforation, the condition of affairs would be very much the same as would almost certainly follow appendicectomy, and the fæcal fistula and septic infection, which would probably have developed as a result, would have arisen in the natural course of events. The abdomen was, therefore, closed in layers in the usual way, without any interference with the morbid condition present. The patient made an uninterrupted recovery, the wound healed per primam, and no further trouble has been experienced.

CASE 3.—The patient, E. F., a married woman aged 29, was admitted to hospital 21/9/19 with an attack of abdominal pain and vomiting of eight days' duration. She was five months pregnant. The attack was typical of appendicitis, the pain commencing in the region of the umbilicus and later settling in the right iliac fossa. Some vomiting at the onset had not persisted and the raised temperature had diminished. There had been marked constipation since the commencement of the attack. On examination the general condition of the patient was fairly good, though she presented the appearance to be expected after a week's illness. The tongue was thickly coated and the breath foul. Temperature 100° F., pulse 108. The abdomen presented a mid-line swelling corresponding to the five months' pregnant uterus. There was some rigidity and tenderness in the right iliac fossa, not marked, and the patient asserted that palpation was much less painful than it had been. No mass was felt. The diagnosis of acute appendicitis was accepted, but in view of the improvement in both general and local conditions it was decided to leave her alone. Her constipation was treated and she went home in a few days. The presence of pregnancy here was the chief deterrent to operation, especially as the appendicitis was clearing up. The danger that the pregnancy might predispose to a further attack was considered less than that of production of a miscarriage by operation after the acute attack had subsided, so that no action was taken.

CASE 4.—The patient, G. H., a male aged 30, was admitted to hospital 3/8/19 suffering from "diarrhœa," following an attack of abdominal pain 12 days previously. The history was again typical of appendicitis, the pain being general at first, and later settling down in the right iliac fossa. There was vomiting at first, and some difficulty and pain in micturition. The general condition had improved the last few days, and the abdominal pain lessened, but patient had developed what he described as diarrhœa the last two or three days. On investigation this proved to be the frequent passage of a small quantity of mucus, but there had been no incontinence.

On examination his general condition was good, his tongue moist and furred. Temperature 100·2° F., pulse 100. Locally there was slight tenderness and rigidity towards the inner part of the right iliac fossa, and on deep palpation a mass could be felt on the right side of the pelvis, resonant on percussion. Per rectum this same mass could be reached high up with the tip of the finger and readily demonstrated bimanually. The diagnosis was that of acute appendicitis with perforation and pelvic abscess pointing into the rectum at its upper part. The absence of any patulous condition of the anus and the height of the abscess contra-indicated its being opened by the bowel, as there was probably gut between it and the floor of the pelvis, and, seeing that it was pointing into the upper part of the rectum, there was no indication to approach it by the abdominal route. Left alone it discharged into the rectum in less than 24 hours, giving rise to offensive diarrhœa, with pus in the stools. The temperature and pulse at once fell to normal and continued so. He was discharged from hospital after a week.

CASE 5.—The patient, I. J., a married woman aged 33, was admitted to hospital 30/10/19 suffering from an attack of abdominal pain of 14 days' duration, with the development of a lump in the right iliac fossa. The history was that of an attack of acute appendicitis, with perforation, except that there had been no vomiting. A lump had gradually appeared in the right iliac fossa, and had steadily increased up to the time of her admission. The attack was not associated with any menstrual disturbance. She gave a history of a similar attack three months previously, with the development of a lump in the same way. It became quite large and then appeared to vary. When she had diarrhœa it became less. Finally it ceased to enlarge and gradually disappeared.

On examination her general condition was good; she was high-coloured and of more than average stoutness. Her tongue was moist and furred, her breath somewhat fœtid. Temperature 101° F., pulse 128. Locally a large mass, the size of a coconut, could be seen occupying the right iliac fossa. It was tender on pressure, but there was no rigidity over it. It was hard, smooth, and well defined, fixed to the right iliac fossa, and resonant on percussion. There was no flexion of the right thigh. The diagnosis made was that of acute appendicitis with perforation and abscess formation, the appendix occupying the subcæcal as opposed to the retro-cæcal position. The view taken of the previous attack was that an abscess had formed in the same situation and that it had burst into the cæcum, giving rise to the attacks of diarrhœa. Owing to the friability of the walls of the abscess and the danger attached to the separation of the adhesions, which are very dense by this time, coupled with the fact that in a proportion of the cases it is impossible to identify the appendix, it was decided to drain the abscess and do nothing more. This was accordingly done, the patient making a straightforward recovery. She was given instructions to return in six months to have the appendix removed, as it was almost certain that she would have recurrent attacks.

Cases Sent in as Acute Appendicitis.

CASE 6. *Tuberculous mesenteric glands.*—The patient, K. L., a boy aged 14, was admitted to hospital 4/10/19 as a case of appendicitis. The doctor was called to see him the night before, when he had "great pain over McBurney's point, vomiting, and some slight rigidity in that region. Temperature 99° F. He had, it appears, a similar attack some months ago." On admission he was not very robust, but though he did not look ill he had the facies associated with tuberculosis. Temperature and pulse were normal, and tongue clean. Locally the abdomen was not distended, and on palpation it had the "doughy" or "podgy" feel which is so characteristic of those in whom tuberculous mesenteric glands are found. Two separate small masses were readily felt, which were tender on pressure, but no rigidity was noted unless pressure were applied over the masses. The larger mass was situated in the right iliac fossa, the smaller rather above and to the left of the umbilicus. It was decided that the larger mass comprised tuberculous glands in the ileo-colic angle and the smaller a similar condition in the root of the mesentery. No operative measures were advised and the boy improved and went home in a few days, with instructions to carry out treatment appropriate to the condition.

CASE 7. *Tuberculous mesenteric glands.*—The patient, M. N., a boy aged 7, was admitted to hospital 8/10/19 as a case of acute appendicitis. For some days past he had complained of pain in the abdomen, with irregular vomiting and constipation. On admission he was a small, thin, weedy boy, with the typical tuberculous facies. He was very lethargic. Tongue was somewhat furred. Temperature 98° F., pulse 92. Locally his abdomen was not distended, and on palpation there was the same markedly "doughy" feeling which was present in the last case. An irregular nodular tender mass was felt nearer the mid-line and closer to the umbilicus than the usual appendix abscess. There was no rigidity except when the mass was pressed upon. Diagnosis was of tuberculous glands in the ileo-colic angle. No operation was advised and with general treatment his pain and constipation disappeared, and he improved greatly. An interesting feature of the case was the occurrence of two rises of temperature, 100.2° and 99.4°, on the third and twelfth days respectively, both of which fell to normal by a short lysis. This nine or ten days' cycle of temperature elevation is very common in cases of tuberculosis, and its occurrence has been especially emphasised by Mr. W. G. Richardson, surgeon to the Royal Victoria Infirmary, Newcastle-upon-Tyne. On his discharge from hospital the parents were given instructions as to his mode of life, fresh air, feeding, &c.

CASE 8. *B. coli infection of urinary tract.*—The patient, O. P., a married woman aged 28, was admitted to hospital 8/10/19 as a case of acute appendicitis, the history extending over a period of a week. On investigation there was nothing to suggest appendicitis except pain in the right side, shooting into the groin, and tenderness on pressure over that area. The attack had commenced a week previously with increased frequency of micturition, difficulty in commencing, and pain at the end of the act, referred particularly to the vulva. During the last three days the pain had extended into the right iliac fossa and right loin, so that, at the time of her admission, the pain appeared to commence at the anterior part of the loin and radiated into the groin, and it was associated with a desire to micturate. The increased frequency of micturition was still present and pain at the end of the act. There had been no vomiting since the onset of the attack, and she suffered from obstinate constipation.

On examination her general condition was good, and she was somewhat flushed. Temperature 100° F., pulse 102. Locally there was no distension of the abdomen. She was tender on pressure over the right kidney and along the ureter, but no rigidity was present and no mass was felt. There was no vaginal discharge. A provisional diagnosis of *B. coli* pyelitis and cystitis was made, and a catheter specimen of urine sent to the bacteriologist. X ray examination revealed no shadow suggestive of calculus. Aperients were administered and urinary antiseptics and diuretics given, and within three or four days the whole condition had completely cleared up. The bacteriological report confirmed the presence of *B. coli* in the urine in pure culture, with some pus cells.

CASE 9. *Retention of urine.*—The patient, Q. R., an unmarried female, aged 20, was sent to hospital as a case of acute appendicitis 28/10/19. On the night of 27th she went to bed feeling all right, slept all night, and was awakened at 6.30 A.M. with severe pain in the right hypogastrium, which she described as of a stabbing nature, and which continued with remissions until her admission on the afternoon of the 28th. She wanted to pass urine, but was unable to do so, none having been passed since the night of the 27th. There had been no vomiting, but she suffered from constipation. Menstruation had been regular, and had occurred four days before the onset of the attack. She gave a history of a similar attack two months previously, with retention of urine, which had had to be relieved by catheter, and she was quite well after the administration of a purgative. This attack was preceded by a week of obstinate constipation.

On examination she looked pained and anxious. Tongue furred and moist, temperature 99° F., pulse 100. Locally, there was marked distension of the hypogastrium, and the distended bladder could be seen and felt extending to within 2 in. of the umbilicus. It was tender on pressure, and she complained more of pressure over the right side than the left. There was no rigidity of the belly wall. Per rectum nothing was felt, except the cervix uteri, which was normal in position and condition, thus excluding the possibility of a retroverted gravid uterus. The diagnosis of acute appendicitis was not entertained, and the bladder was emptied and an enema given with excellent result. She expressed herself as greatly relieved, the pain disappeared and her tenderness rapidly cleared up, and she was discharged from hospital quite well three days after her admission.

CASE 10. *Movable kidney with hydronephrosis.*—The patient, S. T., a married woman, aged 41, was sent into hospital 31/10/19 as an appendix abscess on account of a mass, situated on the right side of the abdomen, about the level of the umbilicus. She gave a history of occasional attacks of pain in the right loin, which did not come on suddenly and which were never very severe, though the degree of severity increased for some time after the onset. These attacks of pain were associated with increased frequency of micturition, but there was no vomiting. When the attacks passed off she noticed the passage of an increased quantity of urine. She said the attack for which she had been sent to hospital was similar to these, and was still in progress.

On examination she was thin, but did not look ill. Temperature 98.8° F., pulse 80. Locally the abdomen was rather of the scaphoid variety, and examination was easy. There was no rigidity of the belly wall, and a mass was readily felt on the right side, above the level of the ordinary appendix abscess, on a line opposite the umbilicus. It presented all the physical signs of a kidney, being somewhat larger than normal, and having instead of a depression in the region of the hilum, a tense, more or less spherical swelling, the kidney tissue encircling it on its upper, outer, and lower parts in a crescentic manner. X ray examination revealed no shadow suggestive of calculus. The diagnosis made was "movable kidney with obstruction to the outlet of urine from the pelvis and consequent hydronephrosis." She was given aperients for her constipation and with rest in bed the hydronephrosis disappeared accompanied by the passage of an increased quantity of urine. The kidney remained as before, but the swelling in the region of the pelvis had gone. She was ordered a belt in preference to operative treatment.

CASE 11. *Pneumococcal peritonitis.*—The patient, U. V., a girl 9 years of age, was sent to hospital 2/10/19 as a case of acute appendicitis with general peritonitis. She was admitted on the fifth day of her illness, and the following irregular story was given by the parents. She complained at first of headache and was feverish and ill on the Sunday and Monday. On the Tuesday she felt able to go to school, but had to return home in the afternoon. On the Wednesday, for the first time, she complained of pain in the abdomen, apparently generalised and accompanied by diarrhœa. The abdominal pain rapidly became worse, and vomiting began and continued, the diarrhœa passing off.

On admission, she was crying out continuously with the pain in her abdomen, and she lay huddled up in bed, with the thighs flexed on the abdomen. She looked extremely ill, with hollow eyes and sunken cheeks, slight cyanosis, some embarrassment of the respirations, lips dry and cracked, and tongue coated with a brownish fur and dry, while there were sordes on the teeth. Temperature 103.8° F., pulse 124, varying. Capillary circulation very bad. The abdomen was examined with considerable difficulty, on account of the pain it gave her to lie on her back and straighten the legs at all. There was general distension, and rigidity and tenderness were very marked, and of equal degree all over the abdomen. There were no masses to be felt and no localising signs. Free fluid was not demonstrated. As in the case of the hands, the capillary circulation of the belly wall was very bad. No evidence of pneumonia was elicited. A diagnosis of pneumococcal peritonitis was made, the points in favour being the irregular history, the high temperature, the early diarrhœa, the rapid development of peritonitis, without the history of rupture of an appendix, and the sex and age of the patient. No interference was advocated, though this, on account of her general condition, would still have been the case had the diagnosis of acute appendicitis been confirmed. In spite of hot poultices, sitting posture, and rectal saline, she died on the fourth day, and post mortem and bacteriological examination the diagnosis of pneumococcal peritonitis, without pneumonia, was verified.

CASE 12. *Gonococcal peritonitis.*—The patient, W. X., 25 years old, was sent to hospital 8/9/19 as a case of acute appendicitis. The diagnosis was based on the presence of acute tenderness and some rigidity in both iliac fossæ of four days' duration. It commenced with increased frequency and smarting pain during micturition, and a heavy bearing-down sensation. Patient also complained of continuous pain in both iliac fossæ extending up towards the sides. There had been no vomiting with the attacks. Bowels constipated. Menstruation had always been regular, but her last period had continued a little longer and the discharge had been a little more profuse than usual.

On examination she looked feverish and ill. Her tongue was furred and moist, breath not fœtid. Temperature 100·8° F., pulse 88. Locally there was no distension of the abdomen, but she was extremely tender in both iliac fossæ and over the pelvis, and there was some, though not excessive, rigidity in the same regions. No mass could be felt, and there was no free fluid demonstrable. There was a purulent vaginal discharge present. Per vaginam there was marked tenderness in the fornices, but no mass was to be felt. A diagnosis of gonococcal peritonitis was made, and no operative interference advised. A swab of the vaginal discharge and a catheter specimen of urine were sent for bacteriological examination. The vaginal discharge contained diplococci indistinguishable from gonococci, and the urine showed the presence of *B. coli*, but contained no pus. With poultices and general treatment the patient ultimately made an excellent recovery, the temperature rising to 104° on the sixth day and becoming normal on the eleventh. Subsequently there was no further trouble.

Cases of Intestinal Obstruction.

CASE 13. *Strangulated umbilical hernia, with diabetes.*—The patient, Y. Z., a widow 51 years of age, was admitted to hospital 4/9/19 suffering from a strangulated umbilical hernia of two days' duration. She had had an umbilical hernia for many years, which had steadily increased in size and which had been the cause of repeated attacks of griping abdominal pain and vomiting. The last attack had been very severe, the pain being continuous, with exacerbations, the vomiting excessive, gradually becoming more and more offensive as time went on, and there had been complete arrest of flatus from the onset up to the time of admission. A few hours before coming to hospital she thought the pain had become less severe and the vomiting less frequent.

On examination she was a very stout woman, weighing about 16 st., somewhat cyanosed, with marked respiratory embarrassment and wheezing breathing, and she looked hollow-eyed and ill. Her breath was offensive and tongue thickly coated. Temperature 97·8° F.; pulse 92, soft, and of poor volume. The urine contained sugar. A large umbilical hernia, soft and free from tenderness for the most part, was present, but the upper portion, the size of an orange, was hard, tense, and tender. On account of the patient's general condition, the diabetes, the poor quality of the pulse, the bad chest, and the excessive fat, operative interference was not advisable, the chief deterrent being the glycosuria. The amelioration of the symptoms, pain and vomiting, might be regarded equally well as evidence of gangrene of the strangulated gut or relief to the obstruction, and an enema was administered with a view to finding out whether the gut was completely obstructed or not. The result of the enema was a little hard scybala and a small quantity of flatus. The latter was interpreted as indicating only a partial gut obstruction, and thus her best chance appeared to be the administration of further enemata, sodium bicarbonate being given per rectum for the diabetes. This treatment proved successful, and she made a straightforward recovery, leaving hospital before the end of a week.

CASE 14. *Double congenital cystic kidneys—uræmia, with obstructive symptoms.*—The patient, B. A., a married woman aged 49, was sent to hospital 21/8/19 under the care of Mr. Richardson as a case of chronic intestinal obstruction with a mass on the left side of the abdomen. The history extended over a period of nine weeks, during the greater part of which she had been bedfast and had suffered from severe and constant headache. She had lost a considerable amount of flesh and latterly complained of persistent thirst. For the week previous to admission she had had a great deal of pain in the left side of the abdomen, and her bowels had not been moved during this time, aperients failing to give her relief. There had been no arrest of flatus. A large mass had been discovered emerging from under cover of the left costal margin. During the last two days the headache had become much worse and the patient now complained of much pain in the left hip with loss of power in the leg.

On examination she was a fairly well-nourished woman, but looked quite ill. Tongue rather dry and furred. Temperature 100·4° F., pulse 112. Urine contained no albumin. Locally there was no general distension of the abdomen and no visible peristalsis. A mass could be seen projecting from under the left costal margin and extending towards the umbilicus. This mass presented all the physical signs of a kidney swelling, and it was distinctly nodular on the surface, the colon occupying its anterior and mesial aspects. On examining the right flank the corresponding kidney could also be felt, somewhat enlarged, but much less so than the left. X ray examination revealed no shadow suggestive of calculus. The diagnosis made was, therefore, congenital cystic disease of both kidneys, with uræmia, the manifestations of the latter condition being the headache, thirst, and loss of flesh, and the not uncommon simulation of intestinal obstruction. It is scarcely necessary to say that operative interference was not advocated, enemata and aperients leading to the disappearance of the obstructive symptoms and light diet and abundance of liquids producing a marked amelioration of the uræmic manifestations. She left hospital at the end of a fortnight considerably improved.

Other Types of Case.

CASE 15. *Leaking duodenal ulcer.*—The patient, D. C., a man aged 58, was admitted to hospital 30/10/19 because of an attack of acute abdominal pain. The history was that 36 hours before admission, when walking outside on his way to work, he was suddenly seized with an extremely severe pain in the upper abdomen, the worst he had ever had in his life. It completely crippled him, and he had to be helped home. He did not vomit at the time of onset, but since then he had vomited everything he had taken. For the past few months he had been much troubled with indigestion, pain coming on regularly about half an hour after meals. With it there had been no vomiting, but a good deal of "belching." There had been no previous similar attack.

On admission his general condition was not good. He had obvious trouble with his chest, emphysema and bronchitis, and he looked ill. Temperature 96·8° F., pulse 100, of very poor quality. There was a trace of sugar in his urine. Locally there was no distension of the abdomen. There was very marked rigidity and tenderness in the upper half, especially on the right side, where the rigidity was boardlike. He was tender in the lower half of the abdomen also, but rigidity was much less pronounced. There was no evidence of free fluid or gas. The diagnosis made was a ruptured duodenal ulcer, with a small leak, which, though affecting the general peritoneal cavity at the beginning, was at the time of admission shut off, as evidenced by the distribution of the rigidity and the absence of free fluid or gas. It was decided to leave him alone, and if a localised abscess formed to deal with it later. If the diagnosis of a limited leak were wrong, then the time since the rupture, coupled with his bad general condition, supported the non-operative treatment, and his best chance was to be left alone. The sugar in his urine was an additional reason against operation. He was propped up in bed, poultices were applied to his abdomen, and saline was administered per rectum. Sedatives were ordered only to be given if he complained much of pain. His abdominal condition slowly cleared up without abscess formation, and his chief trouble in hospital was his chest. His pulse was irregular at times, and he had much breathlessness, with bronchitis and muco-purulent expectoration. His pleura was watched for empyema, but none developed. After a somewhat slow convalescence he was discharged from hospital greatly improved.

CASE 16. *Rupture of kidney by a kick.*—The patient, F. E., a man of 20 years of age, was admitted to hospital 31/10/19 as a case of ruptured kidney. The history was that three days previously he had been kicked in the right side by a horse. Since that time he had been confined to bed, had suffered a good deal of pain, and had passed much blood in the urine. The last urine he had passed was thick and brownish. Since the injury there had been no vomiting, and his bowels had been regular and motions normal.

On examination he was a healthy-looking youth, with no evident anæmia. Temperature 99·6° F., pulse 84. Locally he complained of a dull aching pain in the right loin, and there was considerable tenderness on deep palpation over the right kidney. There was no rigidity till deep pressure caused him pain. No distinct mass was made out, but bimanually there was the feeling of a thickening in the flank, suggestive of a perirenal hæmorrhage. There was nothing abnormal in the rest of the abdomen. A specimen of urine obtained showed obvious blood, but no clot was present. No operative interference was entertained, the pulse being watched for evidence of hæmorrhage. The patient made an uninterrupted recovery, the blood in the urine varying a little but gradually clearing up, and no increase of swelling appearing in the kidney region suggestive of extravasation of urine. He had one attack of typical renal colic associated with the passage of a minute clot.

The following cases are of interest in that, though they are of the same class as those in which no radical operation was advocated, some special feature necessitated a change of attitude and course.

CASE 17. *Acute appendicitis with perforation and abscess, and tuberculous cæcum and glands.*—The patient, H. G., a boy aged 7, was admitted to hospital 25/5/19 as a case of acute appendicitis with abscess. The history was of two days' duration, typical of appendicitis. On the first day he had a good deal of pain referred across the abdomen about the umbilicus, with vomiting. On the second day the pain was much better, but on the third morning, a few hours before admission, it reappeared with increased severity in the right iliac fossa. There was no history of any previous attack; indeed, he had been exceptionally healthy and had lived a very active, open-air life.

On examination he was a thin, tuberculous-looking boy, and appeared to be quite ill. His tongue was thickly coated with brown fur, and his breath was offensive. Temperature 100·4° F., pulse 106. Locally he had a definite, localised, tender mass in the right iliac fossa, with some rigidity over it. It was resonant on percussion. There was no rigidity or tenderness of the rest of the abdomen. A diagnosis of subcæcal appendix abscess was made, and operation proceeded with. On opening the abdomen there was a considerable quantity of free, clear fluid, suggestive of tubercle. The mass was formed chiefly of omentum, enclosing an acutely inflamed and perforated appendix, and a small quantity of pus. The appendix was rather conical in form, about the thickness of a thumb-end at its base. It contained two large concretions and was perforated just at its attachment to the cæcum. The cæcum presented a plaque of thickening in its wall suggestive of tubercle, but there were no tubercles on its peritoneal surface. There were numerous tuberculous glands in the ileo-colic angle and in the mesentery. There was no choice but to remove the appendix. A clamp was put on at its base, but it cut completely through, detaching the appendix completely from the cæcum. It was removed. Considerable difficulty was experienced in dealing with the hole left in the cæcal wall, on account of the thickness and rigidity of the latter, and also as it was situated at the line of reflection of the peritoneum on to the iliac fossa. It was necessary to mobilise the cæcum somewhat and to take large bites of its wall in order to get a satisfactory invagination, and this suture was reinforced by adjacent tags of fat and the omentum on account of the very real fear of a tuberculous fæcal fistula developing. A drainage-tube was left in and the belly wall was sutured in layers. The boy, fortunately, made an uninterrupted recovery. In this case the site of the perforation and the presence of tuberculosis were almost certain to result in a fæcal fistula if no radical operation had been performed, and the operation gave the only hope of avoiding this most serious complication. Sepsis had already been added to the tuberculous infection, and the operation was certainly of value in helping to combat it.

CASE 18. *Acute appendix abscess, with tuberculous mesenteric glands.*—The patient, J. L., a boy of 12, was admitted to hospital 5/11/19 as a case of appendicitis of four days' duration. He gave a typical history of appendicitis, with pain first across the abdomen and later in the right iliac fossa, vomiting at the onset of the attack, and then elevation of temperature. He had had some difficulty with micturition and pain during the act during the last two days. He had had no previous similar attack. He had been treated for lupus since being quite a small boy, and was still attending the infirmary for treatment.

On examination his face was almost completely bandaged up, and he had widespread lupus. His tongue was furred and dirty, and his breath offensive. Temperature 98·8° F., pulse 128. Locally there was a large mass in the right iliac fossa, extending down into the pelvis, and resonant on percussion. He was rigid and tender over the mass, but the rest of the abdomen had the markedly "doughy" feeling typical of tuberculosis. Diagnosis made was appendix abscess, but the presence of tuberculous mesenteric glands was thought very probable. On opening the abdomen a large pelvic appendix abscess was found, and in addition extensive tuberculous mesenteric glands were present, especially large in the ileo-colic angle. On evacuating the appendix abscess a free stercolith was removed, and on inspecting its wall the appendix was seen to be acutely inflamed and presenting a large perforation at the site of a marked kink. It was tightly bound down and could not be mobilised, but, as it was certain to lead to further attacks if the perforation healed, it was removed base first, the mucous membrane being pealed out of the peritoneal and muscular coats. The inversion of the stump was not difficult and was satisfactorily accomplished. The abscess was drained. The patient made a straightforward recovery.

CASE 19. *Acute appendicitis, with pregnancy of five months' duration.*—The patient, L. K., a married woman of 28 years of age, was admitted to hospital 17/11/19 suffering from an attack of acute appendicitis. The history given was that 12 hours before admission she was seized with severe pain across the abdomen and in the right iliac fossa associated with vomiting. She had had one previous attack, which was less severe than the present one. She was five months' pregnant, and her pain had no resemblance to menstrual or labour pain, and there was no vaginal hæmorrhage with the attack.

On examination she looked ill, had a somewhat sunken-eyed and anxious expression, sordes on the teeth, and a very dirty brown-furred dry tongue, with fœtid breath. Temperature 99·8° F., pulse 120. Locally the abdomen presented a large mid-line swelling in its lower part, which looked and felt like a five months' pregnancy. She was acutely tender and rigid in the right iliac fossa, but no mass was to be felt. On account of the general and local condition of the patient and the shortness of the history, an acute appendicitis with gangrene was diagnosed and immediate operation advised. Operation revealed a much more advanced condition than the history suggested, and there was a large quantity of free milky fluid present with an acutely-inflamed, non-perforated appendix. The appendix was removed in the usual way, and the stump invaginated and the abdomen closed completely, in spite of the amount of milky fluid, in the hope that the peritoneum might be able to deal with the infection.

On examination of the appendix the mucous membrane was gangrenous, but there was no perforation, the infection having taken place through its wall. In another 24 hours it would have been completely gangrenous. The attack had, no doubt, been in progress before the onset of symptoms, and these latter only represented the period from the commencement of obstruction of the lumen. The condition did not clear up in the manner hoped for, and on the third day pus escaped between two of the stitches in considerable quantity, coming from a considerable depth. The subsequent course was similar to that of an ordinary appendix abscess and she was discharged from hospital quite well, no trouble having arisen in connexion with the pregnancy.

CASE 20. *Late appendix abscess, appendix entirely sloughed off from cæcum.*—The patient, N. M., a man of 54 years of age, was admitted to hospital 17/11/19 with an appendix abscess extending into the pelvis. The history was typical and the duration eight days. His general condition was fairly good. Temperature 99·6° F., pulse 80. Operation took place nine days from the onset. The abdominal wall was markedly œdematous and the muscle layers matted together with inflammatory exudate. The peritoneum was incised and an abscess cavity was opened into containing typical *B. coli* pus. On evacuating this the cavity was seen to be between the omentum and the belly wall. A finger was introduced, and it passed readily into a second deeper abscess cavity; this was opened up and evacuated and a free stercolith removed. The cavity extended well down into the pelvis. On examining its wall a small hole was seen where the appendix had completely sloughed from the cæcum, and the open mouth of the appendix base could be distinctly seen. It was evident that the usual procedure of simply draining these abscesses of long duration was contra-indicated, and it was necessary to remove the appendix. The dense nature of the adhesions all around and the friability of the whole abscess wall prevented any mobilisation of the appendix, and it was accordingly removed base first, its mucous coat being shelled out of its peritoneal and muscular coats. The hole in the cæcum was sutured with through-and-through catgut and invaginated with silk, very large bites of the cæcal wall being necessary to prevent the silk from cutting through. The cavity was drained. The patient made an uninterrupted recovery.

REMARKS.

The following are a few of the points which the above cases would appear to indicate, which, though by no means new, are worthy of recapitulation :—

1. In this class of work the ease of the average operations is prone to lead to carelessness in making a diagnosis, and so result in inferior judgment.

2. No hard-and-fast rules can be made; general principles ought to be laid down and followed, and special features of individual cases must be taken into consideration before a final decision as to treatment can be adopted.

3. The accepted contra-indications to operative interference still hold good. They are general and local, the general comprising heart, lung, and kidney disease (phthisis, chronic emphysema and bronchitis, uræmia, and, in the absence of organic disease of the heart, the rapid feeble pulse, cyanosis, cold blue hands, and bad capillary circulation associated with failure of the circulatory apparatus), diabetes, and so on. Examples of the local contra-indications are found in the presence of tuberculous peritonitis, where complications such as the possible addition of sepsis or the development of a fæcal fistula are such serious events. Also the presence of pregnancy deserves special consideration. In such cases judgment must depend on the relative seriousness of the condition already present and that recently superadded, and only where the latter is regarded as the more important must the former be ignored.

4. The chief objects of operation everywhere in the body are still to deal with hæmorrhage, sepsis, mechanical obstacles, or to remove a focus of disease (Rutherford Morison), or, in the case of injuries to the viscera, to deal with the lesion and remove extravasations of the specific secretions or excretions. Where these objects cannot be attained it is usually not wise to operate. A good example of this is seen in pneumococcal or gonococcal peritonitis, where until the infection, a general one, is sufficiently localised by Nature's efforts as to result in an abscess operative interference can only do harm.

5. In the cases of mistaken diagnosis, though at times differentiation is impossible, the error commonly arises from imperfect investigation in relation either to the history or the examination of the patient. This is well exemplified in appendix cases, where sufficient attention is not paid to the typical sequence of (1) pain, (2) vomiting, and (3) a rise of temperature, which is credited to Murphy, but which has been taught here for 25 years.

6. All surgical emergencies should be treated in a properly equipped hospital and every patient with a more than ordinary abdominal illness should be sent to such a hospital *at once* for observation and, if necessary, operation.

THE INCIDENCE OF
NOSE, THROAT, AND EAR DISEASE AMONG AVIATION CANDIDATES.

BY DAVID RANKEN, M.S. LOND., B.S. DUNELM, F.R.C.S. ENG.,
SQUADRON LEADER, ROYAL AIR FORCE MEDICAL SERVICE
ASSISTANT SURGEON, FLEMING HOSPITAL,
NEWCASTLE-ON-TYNE.

THE statistics on which this contribution is based have been obtained from the records of examinations held both at the Aviation Candidates Medical Board, Hampstead (Tables A and B), and at the various reception depôts of the Royal Air Force in the United Kingdom (Tables C and D). By the term aviation candidate is meant any adult who presents himself for medical examination with a view to becoming a pilot or observer.

The great majority of the candidates were between the ages of 18 and 23, and those obviously unfit were eliminated by a preliminary medical examination conducted at one of the reception depôts in the various areas of the United Kingdom. Those who passed this examination were sent to the Aviation Candidates Medical Board, Hampstead, and subjected to a more searching examination. Most of the candidates belonged either to respectable working families or to the middle classes—e.g., artisans, clerks, school teachers, engineers. There was a fair sprinkling of better class and public school youths, but neither the aristocracy nor the slums contributed to a marked extent.

Among those also examined at the Medical Board, Hampstead, were officers and other ranks seeking transfer from their units to the R.A.F. Many cadets likewise presented themselves, but it may be assumed that all had had a preliminary examination similar in severity to that conducted at the reception depôts. A certain number of the candidates had two or more defects and are therefore included under two or more categories in Table A.

Standards Required.

1. *Dental treatment.*—This was advised when candidates had two or more carious teeth or stumps. The worst cases were temporarily deferred until satisfactory treatment had been adopted. The fact that 31 per cent. of the candidates seen at Hampstead needed treatment speaks for itself.

2. *Tonsils and adenoids.*—Operative treatment was required when disease or hypertrophy was present with accompanying symptoms or signs.

3. *Deflected septum.*—In recommending submucous resection it was kept in mind that symptoms apparently trifling in importance on the ground tend to become considerably aggravated in the air.

4. *Chronic suppurative otitis media*, unilateral or bilateral, also the radical mastoid operation and dry perforation of the drum, were all causes for rejection. A healed antrotomy with satisfactory hearing and a sound membrana tympani was not included as a prohibitory cause.

5. *Hearing defects.*—(Candidates rejected under Section 4 are not included in this section.) The standard of hearing adopted was that a forced whisper should be heard at a distance of 20 feet by either ear, with the other occluded. Chronic catarrh accounted for a great many of the failures. Cases where it was thought that treatment might bring the hearing up to standard were temporarily deferred and re-examined at a later date.

6. *Scarred drums.*—Were not considered a cause for rejection unless obviously liable to break down under alterations of atmospheric pressure. The fact that pain, especially on descent, was a likely symptom was duly noted.

7. *No defects.*—Under this heading are included those in whom none of the preceding defects were found. It must not be understood, however, that much rarer conditions such as cleft palate, or slight abnormalities causing no symptoms, were not occasionally found.

The following two tables (A and B) deal with candidates examined at the Medical Board, Hampstead. Table A deals with the commonest defects discovered among 5000 presumably A 1 aviation candidates. Attention must again be drawn to the fact that many of these were included in two or more of the above headings. It will also be noted that the percentage results for chronic suppurative otitis media and hearing defects agree very closely in the two tables. These results are approximate only and are not worked out to the nearest decimal.

TABLE A.—*Analysis of Nose, Throat, and Ear Defects of 5000 Aviation Candidates, presumably A I Men, Examined at the Aviation Candidates Medical Board, Hampstead.*

Treatment required and defects	No	Per cent		Treatment required and defects	No	Per cent	
Dental treatment	1548	31		*Hearing defects*, unilateral	11	0 25	0 61
Removal of tonsils	219	4 5	7 9	Ditto bilateral	18	0 36	
Removal of adenoids	56	1 1		*Has had mastoid operation*	*4	0 08	
Removal of tonsils and adenoids	115	2 3		Scars, unilateral	143	3 0	4 2
Submucous resection	109	2 2		Do, bilateral	59	1 2	
Chronic sup otitis media, unilateral	72	1 4	1 66	No nose, throat, or ear defects	2745	55	
Ditto, bilateral	13	0 26					

* 1 simple, 3 radical

In studying Table B it should again be noted, as mentioned under "Standards required," that although many candidates rejected for chronic suppurative otitis media suffered, as might be expected, from defective hearing, they are not included under the heading of the latter group.

TABLE B.—*Incidence of Chronic Suppurative Otitis Media and Hearing Defects in 47,069 Aviation Candidates, presumably A 1 Men, Examined at the Medical Board, Hampstead*

No examined	Rejected for various reasons		No with chronic supp otitis media			No with defective hearing		
	No	Per cent	No	E	R	No	E	R
47,069	14 059	30	715	1 5	5	330	0 7	2 3

E, R = Total examined and total rejected percentages.

The last two tables (C and D) deal with statistics obtained at the various reception depôts of the United Kingdom. Many thousands were seen by the medical officers at these depôts, which served the double purpose of relieving the strain on the Hampstead Board, and reducing to a minimum the loss of time and money incurred on the part of obviously unfit provincial candidates in a fruitless journey to London. In Table C the term "aural defects" is used to include chronic suppurative otitis media and hearing defects, it is apparent that a certain number rejected under these headings would also suffer from other physical conditions prejudicial to success.

TABLE C.—*Percentage of Rejected Candidates at Reception Depôts*

Total percentage rejected for all reasons	37
Percentage of total number examined rejected for aural defects	1 4

The last table (D) is an analysis of the aural defects (chronic suppurative otitis media and hearing defects) of 1500 candidates rejected for various reasons at the reception depôts. The numbers are not large but it is interesting to compare the right, left, or bilateral incidence of the defects, especially in view of the large proportion of bilateral hearing defects.

TABLE D.—*Incidence of Chronic Suppurative Otitis Media and Hearing Defects in 1500 Candidates Rejected for Various Causes at Reception Depôts.*

Chronic suppurative otitis media			Hearing defects		
Right	Left	Bilateral	Right	Left	Bilateral
11	13	6	7	4	16
0 7%	0 86%	0 4%	0 46%	0 26%	1 06%
2%			1 8%		

Summary.

Although these tables contain many items which almost speak for themselves, it is not sufficient to regard each individual one as a separate entity. In view of the fact that so many youths from and in different parts of the country were examined, it is possible to form a good idea of the amount of aural disease prevalent among young men of the middle classes. A calculation based on these figures shows that aural disease appears seriously to affect 2·8 per cent. of this part of the population. Similarly the incidence of other diseases, though not considered in the present report, could be adequately estimated.

One obvious conclusion remains to be noted: that much remains to be done before the amount of nose, throat, and ear disease affecting the youth of this country can be said to have been brought down to a negligible factor or an irreducible minimum.

DELAYED ARSENICAL POISONING:

A REPORT ON FIFTY-EIGHT CASES FOLLOWING THE ADMINISTRATION OF "606" PREPARATIONS.

BY GEORGE S. STRATHY, M.D., C.M. TOR., M.R.C.S. ENG., L.R.C.P. LOND.,
CLINICIAN IN CHARGE, MEDICAL OUT-PATIENTS' DEPARTMENT, TORONTO GENERAL HOSPITAL;
THE LATE CAPTAIN C. H. V. SMITH, C.A.M.C.;
AND
BEVERLEY HANNAH, M.B. TOR., M.R.C.S. ENG., L.R.C.P. LOND.,
ASSISTANT PHYSICIAN, HOSPITAL FOR SICK CHILDREN, TORONTO.

DURING the past 18 months there have been numerous reports of cases of poisoning following the administration of "606" preparations. These reports have described only single, or at most a few, cases. We have had the opportunity of seeing a large number of such cases, and the purpose of this paper is to draw attention to their prevalence and the variety of symptoms which may occur. The series reported below were all seen in military hospitals, but during the last four months several additional cases have come under our observation in civil practice.

The idea that syphilis should be treated in its early stages by free administration of salvarsan or neo-salvarsan was supported by the results of this treatment, as shown in the rapid disappearance of symptoms, the freedom from relapses, and the negative reactions readily obtained to the Wassermann test. This led the army medical authorities to adopt the "intensive treatment"—i.e., doses of salvarsan and mercury, administered once a week for seven or eight weeks, followed by a further course a few months later, and, if the Wassermann test was subsequently positive, a third course. It was recommended that the doses of salvarsan should be small at first, until the degree of the patient's susceptibility to arsenic was found. One-grain doses of mercury were advised. Instructions were issued that a physical examination, including tests for albuminuria, should be made before and after each treatment. Medical officers were warned to watch carefully for signs of arsenical and mercurial poisoning. Once a patient was considered non-infective he was sent to his lines or barracks, and the treatment continued at the Venereal Disease Treatment Centre of his district. By this method a patient received efficient treatment with a minimum loss of time from his duties. The day after a treatment he was excused duty or given light duty, but by the third or fourth day he was usually at full duty again. This plan worked successfully until the autumn of 1917, when several deaths occurred of men who had received treatment in the preceding three months. This led to an immediate and thorough investigation by the army medical authorities in England, and it was found that nearly all fatal cases had been treated in one of five centres.

Investigation of these centres showed that instructions had not been carefully followed, that in some cases patients had received repeated doses after symptoms of arsenical poisoning appeared, and that a proper urinary and physical examination had been omitted before giving these treatments.

In January and February, 1918, Captain Smith observed several fatal cases at No. 14 Canadian General Hospital, and reported them at a meeting of the Eastbourne Military Medical Society. Lieutenant-Colonel Strathy took charge of the medical division of this hospital in March, 1918, and together they observed 8 fatal cases. Following on these, the remaining 50 cases of the series came under our observation. The military authorities transferred Colonel Strathy to No. 16 Canadian General Hospital in August, 1918, thus leaving Captain Smith to carry on this work at No. 14 Canadian General Hospital. Influenzal pneumonia caused the death of Captain Smith in October, 1918, and unfortunately most of his records were lost, so that some of the earlier cases can be only incompletely recorded.

It is regretted that, owing to Service conditions, we were unable to follow all cases as long as could be desired. The pressure of work in 1918 and 1919 made it impossible to investigate the cases as thoroughly as we would wish. Colonel Strathy was ordered back to Canada in June, 1919, leaving further observation of the cases to Captain Hannah. The assistance of Captain C. V. Bailey was obtained towards the end of the investigation to study the liver changes from the chemical aspect. It is hoped that he may be able to add further information about the cases in the near future. The delay in publishing this paper is partly due to the fact that the Salvarsan Committee of the Medical Research Committee, England, had all our clinical data from June to September, 1919, for the purpose of including them in their report on salvarsan poisoning.

Fifty-eight cases are here reported. Eight of these were fatal, being the first of the series to come under observation. The remaining 50 cases made a slow but otherwise satisfactory convalescence.

Symptomatology.

Eight cases were sudden in onset and extremely severe and died within a few days. The remaining patients varied in the degree of their severity, but the onset was more gradual, and all left the hospital almost fully recovered. Therefore we have divided the series as follows: I. Fatal cases; II. Non-fatal cases.

Group I. Fatal cases.—In these cases the greatest number of doses of salvarsan given was 11, the least 4. The greatest amount of salvarsan administered, where it was possible to obtain records, was 6·95 g., the least amount 2·2 g. The average time of onset of symptoms after the last dose was 41 days, the longest interval 48 days, the shortest 18 days. One patient was under 20 years of age, four between 20 and 30, and three between 30 and 40 years of age. The smallest number of days which elapsed between the onset of symptoms and death was 2, the greatest 11, the average 5 days. The symptoms in every case were similar. The jaundice of onset was rapidly followed by nausea, epigastric pain, stupor, hæmatemesis, delirium, and death. A typical case is here reported.

Pte. R., age 21, 18 months before admission had had a slight sore on his penis. He did not report it and was not treated at the time. He had had five attacks of gonorrhœa in the previous two years. While under treatment for gonorrhœa in November, 1917, his blood was tested and showed a positive Wassermann reaction. In December, 1917, and January, 1918, he was given seven doses (4·7 g.) of novarsenobillon and seven one-grain doses of intramuscular mercury. Following this he was on light duty, but lacked strength and energy. On March 2nd he felt nauseated and chilly. March 3rd he vomited several times. March 5th he noticed he was jaundiced and his vomiting persisted, so that he could not retain solid or liquid food. The vomit became black. He was so weak he could not sit up. March 6th he was admitted to hospital.

On admission, 11 A.M., he was rational, but drowsy. He vomited frequently. The vomitus was black, and looked like hæmolysed blood. There were no clots. The tongue was furred and the breath foul. His face was cyanosed. Breathing somewhat stertorous. Temperature 98·3° F.; pulse 99; respiration 32. Abdomen slightly distended. Liver palpable just below costal margin. Spleen appeared large on percussion, but was not palpable, probably on account of abdominal distension. Examination of heart and lungs negative. Gonococci present in urethral smear. Leucocyte count, 34,000 per c.mm. Differential count: Polymorphs, 80 per cent.; lymphocytes, 16 per cent.; large mononuclears, 4 per cent. Urine: amber colour, acid, specific gravity 1020, sugar absent, albumin present ++; microscopically, pus cells and red blood cells; no casts. During the day he vomited more than a quart of the black material and some bright red blood. His pulse became weaker, the cyanosis was more marked, but he remained conscious until a few minutes before death, which occurred at 9 P.M.

Death in all cases but one followed rapidly. Four of the patients were wildly delirious. In the case of the patient who lived for 11 days after admission drowsiness came on gradually and slowly deepened until death. In all cases tested the urine contained bile, and in nearly all cases albumin as well. The blood picture was not characteristic. The hæmoglobin and red cells were not much reduced. The leucocytes varied in number from 14,000 to 34,000 per c.mm., and the polymorphonuclear leucocytes from 50 per cent. to 80 per cent.

Group II. Non-fatal cases.—The greatest number of doses of salvarsan given was 14, the least 2. The records showing quantities of salvarsan administered were not always available. The average time of onset of symptoms was 45 days, the longest interval 180 days, the shortest 3 days. Three patients were under 20 years of age, 30 between 20 and 30 years, and 17 between 30 and 50. Thirty-nine of the patients were admitted for jaundice, 8 for dermatitis, 2 for nephritis, and 1 for general debility. Jaundice followed dermatitis in 1 patient, and 2 other cases of dermatitis were followed by peripheral neuritis. Coated tongue, poor appetite, epigastric distress, abdominal distension, headache, general malaise, and loss of weight were noted throughout the group. The blood pressure was recorded weekly in all cases. During the early stages the systolic pressure was frequently below normal. It was often normal and never over 140 mm. As the patient's condition improved the blood pressure returned to normal. A routine urinalysis was carried out every few days with the following results: albuminuria 28 cases, bile salts present 35 cases, increased urobilin and urobilinogen in 16 cases, leucin and tyrosin never found. The microscopical examinations did not show any change of interest. A Wassermann test was obtained in all cases before they left the hospital. All gave a negative reaction with two exceptions; these two remained strongly positive.

Jaundice.

This was the most prominent symptom noted throughout the series, being present in all of the fatal group and 39 of the non-fatal group. It appeared within ten days of the onset of toxic symptoms, and lasted on an average for four weeks. In one case the jaundice was noticeable at the time of the patient's transfer to Canada, five months after its first appearance. Itching of the skin was never present. A marked tendency to somnolence manifested itself, disappearing with the decrease in icterus. The liver was distinctly enlarged in a number of cases, slowly returning to normal size, but never very tender on palpation. The condition of atrophy of the liver in the early stages and following at a later stage on hypertrophy is discussed below under X ray examination. The appetite usually continued small for about two weeks. When this returned there still remained for some days, and in some cases for several weeks, diminished digestive power with a feeling of heaviness and distension in the epigastrium when food was taken.

In the worst cases of this type there was a period of several days in which the secretion of bile was low, evidenced by lack of jaundice, absence of bile in the urine, and clay-coloured stools. A marked feature of these cases was the slowness with which they returned to normal. The average duration of hospital treatment was from two to three months.

The following case is an example of the slow return of bile secretion and liver function:—

Pte. B., age 29, had received 2·3 g. of galyl in six doses and 8 gr. mercury in oil. Fifty days after his last treatment he developed headache, epigastric pain, jaundice, œdema of hands and face, and diarrhœa. Examination showed liver and spleen palpable, and large traces of albumin and bile in the urine. Stools showed bile pigment. The blood picture was normal. Blood pressure 90 diastolic, 140 systolic. He was put on a daily diet of milk 40 oz. and sugar 2 oz., with bicarbonate of soda gr. xlv. Water was given freely. A week later jaundice was deeper, the œdema had disappeared. There was little or no loss of weight, no vomiting or diarrhœa. The liver dullness had become less, the spleen was still palpable, and the stools were clay-coloured. A week later the jaundice was less, the liver dullness on percussion was markedly decreased. (At this stage we had not commenced examining the liver by X ray.) The albumin had disappeared from the urine, but there was still a faint trace of bile. The blood count remained normal. Later the jaundice entirely disappeared, but the stools remained clay-coloured and his digestive powers low. His liver was apparently much atrophied, but he was quite comfortable as long as he was kept on the low diet mentioned. Any increase of diet caused epigastric pain and discomfort. Apparently little or no bile was being formed in the much-damaged liver. Convalescence lasted over six months, but recovery was apparently complete.

Dermatitis.

Eight cases of dermatitis following salvarsan were admitted to No. 16 Canadian General Hospital between March and June, 1919. While dermatitis was the most prominent manifestation, gastric disturbances, congestion of the mucous membrane, loss of weight, and general weakness were also present. Liver changes, similar to those occurring in the jaundice cases, manifested themselves at some time during the illness. The average time for the appearance of this skin condition was usually within two weeks following the course of salvarsan.

It began as a patchy papulo-erythematous eruption, spreading until confluent and until the whole skin was a crimson colour and slightly infiltrated. A few days later desquamation commenced, lasting several weeks. The scales were large, thick, abundant, and without any exudation beneath them. As the exfoliation decreased the infiltration and brown pigmentation of the skin increased, especially over the abdomen and extremities. Four of the cases developed numerous superficial abscesses with elevated temperature extending over a period of three to five weeks. A peculiar condition of the toe and finger-nails was observed in these cases. They became pitted and thickened, followed by splitting and shedding of the nails, and eventually new ones replaced them. The hair of the scalp, axillæ, and pubes fell out, but was gradually growing again at the time the patients left the hospital. A typical case is described below:—

Driver S., aged 37 years, developed a sore on the penis Dec. 15th, 1918. Between 17/2/19 and 20/3/19 he was given five doses of neosalvarsan intravenously and 5 gr. of mercury intramuscularly. On the latter date an irritating red rash appeared on the neck and arms. He was given a further dose of neosalvarsan and mercury. The rash became more severe, and exfoliation followed a few days later. The urine showed albumin.

He was evacuated to England and admitted to No. 16 Canadian General Hospital on 10/4/19. On admission he complained of severe irritation of the skin and conjunctivæ. Exfoliation of the skin was very marked, the conjunctivæ were reddened, and his hair was falling out rapidly. Stomatitis was severe. He had no gastric symptoms. Temperature 102° F. Liver was palpable. Hæmoglobin 85 per cent. Red blood cells 5,800,000 per c.mm. White blood cells 17,000 per c.mm. Differential count showed a slight increase in the polymorphonuclear cells. Blood pressure diastolic 70, systolic 114. On 16/4/19 three large superficial abscesses were present; these were opened. On 25/4/19 liver and spleen were palpable. Skin showed slight brown pigmentation. No bile or albumin in urine. By 5/5/19 several more abscesses had developed. Liver and spleen still palpable. Urine showed no albumin or bile. After this he steadily improved.

Peripheral Neuritis.

In two cases of this group peripheral neuritis occurred. They were both admitted for "exfoliative dermatitis," and developed neuritic symptoms several weeks later.

Pte. P., aged 25 years, was admitted to No. 16 Canadian General Hospital on 16/4/19. Sore had developed on penis 27/12/18. He had received several doses of salvarsan and six injections of mercury. A papular eruption, followed by desquamation, appeared on his body after the fifth injection. Four months after treatment he began to complain of weakness and some numbness in the lower extremities. This condition grew worse. 26/6/19: Examination showed marked weakness of upper and lower extremities, with toe-drop and wrist-drop. Some decreased sensation in hands and feet. Deep reflexes absent. He was unable to feed or dress himself. Two months after the onset of neuritis he was invalided to Canada. At this time he had slightly improved. Deep reflexes were still absent. He was beginning to feed himself, but was unable to walk. Sensory changes had disappeared.

A Case of Arsenical Poisoning due to Fowler's Solution.

A condition very similar to poisoning following salvarsan was found in a patient suffering from arsenical poisoning after the administration of Fowler's solution for psoriasis.

Sgt. F., aged 35, admitted to hospital 24/2/19; had enjoyed good health previously, but had had psoriasis for 15 years. Five months previous to admission he commenced taking Fowler's solution, 5 minims three times a day, and except for short intervals had taken this dose until admission. A month previously he had noticed that the skin of his body and extremities was becoming dark. He had lost 40 lb. in weight, sleep was restless, and appetite very poor. Examination showed nigger brown pigmentation of the skin over all of the body except the head, hands, and feet, and most marked on abdomen, back, thighs, and perineum, with fine bran-like desquamation. Heart and lungs were normal. Blood pressure normal. Liver showed atrophy both on percussion and by X ray. The height of the liver shadow in the right parasternal line in over 50 normal patients was not less than 6 in., whereas in this patient it was 4¾ in. Spleen not enlarged. Urine showed no bile or albumin. He was rested for a month and given milk diet. 31/3/19: Gaining weight and strength. Appetite improved. No change in pigmentation. 7/4/19: Appetite good. Stools normal. 8/5/19: Feels quite well. Full diet. Liver almost normal size, 6¼ in. deep in parasternal line.

This patient, evidently very susceptible to arsenic, developed a chronic dermatitis and atrophied liver from the administration of only 15/100 gr. of arsenious acid daily. His symptoms referable to the liver were almost identical with those of patients who had received salvarsan or neo-salvarsan.

Additional Cases.

The month of August, 1919, brought many convalescent patients to England from the hospital centres in France for immediate transfer to Canada. At No. 16 Canadian General Hospital we observed 11 more cases of "606" poisoning which are not reported in the above series. Time did not permit us to investigate them thoroughly, but they readily grouped themselves according to their outstanding features, as follows: Jaundice, 7 cases; dermatitis, 3; general debility, 1.

Post-Mortem Findings.

As the post-mortem examinations showed very similar conditions in all cases, the autopsy report of Pte. R., whose case is described above, is given as typical;—

Autopsy, 14 hours after death. Body well developed and well nourished. Well-marked icterus of skin and conjunctivæ. Body fat is tinged with jaundice. No free fluid in the peritoneal cavity. Many hæmorrhagic spots, about the size of a sixpence, in the mesentery. Right pleura contained about 50 c.cm. of straw-coloured fluid. Few old adhesions at left apex. The pericardium was normal. Lungs crepitant throughout. Bloody frothy fluid flows from bronchi. Some hypostasis. Heart muscle pale, otherwise normal. Stomach filled with black, unclotted, hæmolysed blood. Mucosa showed considerable digestion, but no ulcers or bleeding points found. Duodenum and jejunum contained black blood similar to that found in stomach. Intestines otherwise normal in appearance. Œsophagus, suprarenals, and pancreas normal. Spleen slightly larger than normal, on section almost diffluent. Liver considerably smaller than normal, capsule wrinkled, on section pale, with nutmeg appearance, friability about normal. Gall-bladder contained 5 c.cm. of normal-looking bile. Kidneys larger than normal, on section very pale, stellate veins congested, cortex swollen, considerable amount of fat in pelves, capsule strips with difficulty. Meninges slightly congested. Brain appears normal.

Anatomical diagnosis: (1) Acute atrophy and degeneration of liver. (2) Slight chronic nephritis and acute cloudy swelling. (3) Mesenteric hæmorrhages. (4) Beginning myocardial degeneration.

Microscopic examinations showed marked damage of the parenchyma of liver and kidneys. The liver lobules were almost unrecognisable, due to the great reduction of liver cords, and where liver cords remained they were remarkably degenerated. The central vein of the lobule was seen supported by the fibrous reticulum. The lobule and Glisson's capsule were infiltrated with round and polymorphonuclear cells. Degeneration and desquamation of the epithelium of the higher tubules were found in the kidneys.

Just before submitting this paper for publication we had the opportunity of seeing an autopsy on a demobilised soldier who died following anti-syphilitic treatment. His history was very similar to the cases in our fatal group, except that he had received only 2 gr. of mercury but 5·85 g. of salvarsan. The liver on section had the appearance which is usually seen in acute yellow atrophy, the cut surface being of a yellowish-brown colour, with numerous elevated areas of a deep red.

Microscopically, degenerating liver cords were seen in the damaged liver lobules.

Ætiology.

Nearly all the observers of salvarsan poisoning have concluded that the benzol group in the salvarsan is the cause of the poisoning. With this we entirely disagree, as we believe that the cases are typical of delayed arsenical poisoning. It is well known that arsenic attacks the liver, stomach, skin, and nerves. These were the main organs of the body affected in the series we are reporting. The symptoms in the case of arsenical poisoning following the administration of Fowler's solution are almost identical with the cases following salvarsan.

It is apparent from the cases reported that age and syphilis are not causative factors. It occurred in all army ages, in all stages of syphilis, and in patients who had never had syphilis. The direct cause of the symptoms is poisoning of the liver, skin, stomach, and kidneys by arsenic. One patient had previously had a wound of the liver which possibly was a predisposing cause and led to a diagnosis of abscess of the liver. The abdomen was opened, which probably hastened death. One patient gave a history of an attack of jaundice five years previously. Three of the fatal cases had gonorrhœa at the time of death. In Dr. Wallace Wilson's fatal case, mentioned below, gonorrhœa was also present. One was alcoholic and had chronic nephritis. One had had nephritis six months previously, and one at autopsy showed a gummous mass as large as a tangerine under the diaphragm. It was composed of brownish material. It is not certain whether this was a pre-existing condition, or was due to the breaking down of the liver from arsenic. No particulars of previous history were available.

It is noticeable that all fatal cases but one occurred between November, 1917, and March, 1918. Routine urinary and physical examinations were then insisted upon before each administration of salvarsan and mercury in all venereal centres.

Preparations Employed.

None of the cases were treated with the original German preparations, but occasional reports of similar cases are published in the recent German literature. Nearly all the patients were treated with substitutes for neo-salvarsan. Some of the patients were given neo-kharsivan, some galyl, and some novarsenobillon. As there are no records obtainable as to which of these preparations was most commonly used, and as we are not able to find records in all cases of the preparations which the patients received, it is not thought that anything would be gained by giving data as to which preparation was given in our cases. The cause of the poisoning was apparently more a matter of injudicious dosage and lack of physical and urinary examination than of the particular preparation used.

The Salvarsan Committee of the Medical Research Committee has investigated the various preparations very thoroughly, and where fatalities have occurred it has tested capsules of the drug from the batch prepared at the same time. Its report will deal with this part of the problem much more thoroughly than we can attempt to do. Our impression is that it is the administration and not the preparation or composition of the drug which is at fault.

In all cases intramuscular injections of mercury were given at the same time as the arsenical treatment. A few of the patients showed slight symptoms of mercurial poisoning, but mercury is known to be an irritant of the kidneys and in excessive doses to cause degeneration of the tubular epithelium, and it seems not at all unlikely that for this reason it acted as a predisposing factor. If the kidneys were damaged by the mercury the elimination of the arsenic would be delayed. There is no evidence that mercury has a toxic action on the liver. Arsenic is stored principally by the liver and is also toxic to the kidneys. It is excreted by the kidneys and also largely by the skin.

We believe that the combination of "intensive treatment" by mercury and salvarsan probably favours the occurrence of arsenical poisoning more than when arsenic and mercury are administered in separate courses. Whether the therapeutic benefits of the simultaneous treatment outweighs these dangers we are not prepared to judge. Since returning to civil practice we have noticed several cases of mild jaundice and slight atrophy of the liver. These are all that have occurred in some hundreds of cases where arsenic and mercury have been administered in separate courses. Dr. Wallace Wilson, of Vancouver, has furnished us with the history of a patient who died in Vancouver three months after a combined course of six novarsenobillon and six mercurial treatments.

Fatalities would probably be avoided in all cases if the patient were examined carefully before and after the treatment, and dermatitis, albuminuria, and bile in the urine excluded. Where possible the liver should be screened at the end of each course, as atrophy can sometimes be diagnosed by this method before any other symptoms appear. The following case illustrates how atrophy of the liver may sometimes precede the jaundice.

Pte. L., age 42, was admitted to hospital 20/2/19, convalescent after influenza. He gave a history of seven doses of salvarsan and seven doses of intramuscular mercury in December and January, so his liver was examined by X ray screen 24/2/19. The liver was seen to be almost entirely to the right of the middle line, the angle formed by the junction of the vertebral and liver shadows was acute, the upper surface of the liver was more dome-shaped than normal. Atrophy of the liver was diagnosed, and against the patient's wishes he was put on a much reduced diet. He did not see why this should be done, as except for slow convalescence from influenza he had no complaints. He felt better, and at his own request he was given two weeks' sick leave and discharged from hospital on 12/3/19. While on leave he ate freely for the first few days, then he lost his appetite, and on 26/3/19 he became jaundiced for the first time and returned to hospital. His liver showed marked atrophy. He was put on the reduced diet again, and by 30/5/19 his appetite had returned, his jaundice had disappeared, and the liver had almost regained its normal size.

Prognosis.

Where the onset is sudden with stupor and vomiting death supervenes in a few days. Where the onset is gradual and no symptoms follow within a month of salvarsan treatment the outlook is good but recovery slow. The appetite returns quickly, but the power of digestion is usually poor for some weeks. In some cases patients were unable to take ordinary diet without discomfort for two to three months. Being soldiers, suggestion may partly account for this. A not unusual feature of the early stage of recovery is the apparent absence or great reduction of bile formation. No bile is found in the urine, the stools are clay-coloured, and there is no jaundice.

Treatment.

As the nature of our first four cases was not understood no systematic treatment was tried. Purgatives were given. Vomiting was so severe that no food was retained. Morphia had to be given to control mania where it was present. Later it was thought that acidosis was a factor. Bicarbonate of soda was given but the cases were rapidly fatal.

In the milder cases the diet was much restricted as it was thought that the power of digestion was limited, and under these conditions toxic products might be formed from food products which could not be assimilated. Each patient was given 30 oz. of skimmed milk and 2 oz. of sugar daily. As they improved, 2 oz. of jam and a slice of bread were added. The diet was intentionally high in carbohydrates and low in fat to aid in combating acidosis. Tea and water given freely allayed the hunger to some extent. Gradually the diet was increased. Absolute rest in bed was ordered. Sodi. bicarb. drachms ii. in 24 hours were given. Except in the fatal cases vomiting ceased when a small diet was given. Loss of weight was slight.

Prophylactic Treatment.

After the cause of the jaundice outbreak was recognised as due to salvarsan treatment, the cases were carefully investigated by the army authorities and all intravenous treatment with salvarsan was discontinued for a few weeks. It was thought that infection might be the cause of the trouble. All the centres which had treated the cases were investigated and a common factor looked for. While the aseptic technique in some centres was found to be not perfect, in others there was no fault in technique. It was then found that the affected patients had not had a proper urinary or physical examination made before receiving repeated doses. The order was then repeated that an examination of urine must be made the day before each treatment and after each salvarsan treatment. Signs of arsenic dermatitis were to be looked for in all cases. After this routine had been rigidly enforced no fatal cases were seen by us.

From observing the patients closely it was found that moderate damage to the liver caused no appreciable symptoms, but when the damage became greater, loss of appetite and then jaundice appeared. If the diet was still free, the damage to the liver still progressing, severe symptoms developed rapidly, leading to death in a few days. If, however, the diet was kept at a minimum, severe symptoms did not follow. It would therefore appear that the severe symptoms of the fatal cases were due to the inability of the liver to handle the products of digestion carried to it, and death ensued from the poisoning of the body by these products. When patients had been only a few days on the low diet an increase in the symptoms, especially epigastric discomfort, was always produced by increased diet. The patients soon learned this themselves, and though at first inclined to take, surreptitiously, diet not ordered for them, they soon found that it caused them so much discomfort that they were satisfied to remain on the low diet ordered.

Examination of the Liver by X Rays.

One of the most interesting facts brought out by the observation of these patients was the changes in the appearance of the liver shadow as shown by X rays. Outlining the liver by percussion is of doubtful value, as it is impossible to be sure of its accuracy. Therefore, use was made of the X ray fluorescent screen in determining the size of the liver in the last 30 cases under observation. A large number of normal cases were examined in order to discover the normal location and outlines of the liver. All patients were examined standing. The level of the upper border of the liver was marked on the patient's skin, and then the lower border marked. Both markings were made at the end of an ordinary expiration. This revealed the fact that atrophy of the liver was common in the cases of arsenical poisoning, but was found in two other patients only. These two patients were both cases of so-called catarrhal jaundice of long standing. It was found that besides the decrease in the depth of the liver shadow atrophy showed itself by changes in the shape and position of the liver. The angle formed by the junction of the liver and vertebral shadows was frequently acute instead of a right angle as in normal cases. The liver tended to be displaced to the right and downwards, very little of the liver being to the left of the middle line of the body. The relaxed capsule permitted the upper surface of the liver to be drawn up into a more dome-shaped outline by the elastic traction of the lung, and the lower border of the liver approached the vertical more nearly than in the normal. In one case of atrophic cirrhosis, the liver being rigid, although atrophied, the change in the shape of the upper surface was not seen.

Schedule of Fatal Cases with Post-mortem Findings.

No.	Name	Age	Stage of syphilis	Treatment. g. = grams. gr. = grains.	Previous history.	Time of onset after treatment in days.	Duration of illness in days.
1	E. H.	Abt 20	Prim.	Salvarsan 7 g. Mercury 7 gr.	Nephritis 6 months previous.	Abt. 29	11
2	Pte. J. S.	21	Prim.	10 doses, 4 g. kharsivan and 10 gr. mercury.	Recent G.S.W.; old wound of liver; old right-sided pleurisy.	70	3
3	Cpl. G. D.	19	Sec.	2·2 g. kharsivan, 5 doses; 8 gr. Hg and some KI.	?	3	4
4	Sgt. O. H.	23	Doubtful history Wass ±	11 doses N.A.B.; Hg 9 gr.	Multiple flesh wounds 10 months. previous. Gonorrhœa 5 months previous.	40	2
5	Pte. J. A. G.	37	Prim.	9 doses N.A.B., 5·85 g.; 8 gr. Hg, 8 doses.	Alcoholic. Has gonorrhœa (? chronic); nephritis.	6	2
6	Pte. J.H. R.	21	Latent for 14 yrs.	7 doses N.A.B., 4·7 g.; 7 gr. Hg, 7 doses.	5 attacks gonorrhœa in two years. Slight, healed, T.B. right lung. Slight chronic nephritis. Heart slightly enlarged and degenerated.	37	13
7	Pte. W. C. R.	38	Latent for 18 yrs.	9 doses N.A.B., 4·65 g.; 7 gr. Hg, 7 doses.	Slight flesh wound 3 months previous. Old pleurisy right side.	35	13
8	Pte. J. S.	—	—	Has had intensive treatment. No particulars available.	No history except hæmatemesis.	—	—

Post-mortem Findings.

CASE 1.—Pericardial and mesenteric hæmorrhages; liver weight 32 oz., semi-fluid; spleen small; 200 c.cm. dark blood in stomach; subacute nephritis.

CASE 2.—Peritoneal hæmorrhages, old right pleurisy, atrophy of liver; degeneration of kidneys, spleen enlarged; hæmorrhage from stomach.

CASE 3.—Small mesenteric, subpericardial and sub pleuritic hæmorrhages, liver weight 32 oz., spleen weight 8 oz., gastric hæmorrhages.

CASE 4.—*Petechial hæmorrhage skin of neck*, mesenteric hæmorrhages, pleuritic hæmorrhages, blood in stomach +++; mass size of walnut in tail of pancreas, containing black, mucilaginous matter, (?) old blood, liver about one third normal size, fibrous; congestion of ileum with film coating it; spleen not enlarged.

CASE 5.—Mesenteric hæmorrhages, spleen enlarged and diffluent; kidneys—slight chronic nephritis; hæmorrhage under capsule of pancreas; pericardial hæmorrhages; a pint of hæmolysed blood in stomach; intestines contain blood; liver normal size, nutmeg appearance due to degeneration of parenchyma, less friable than normal; broncho pneumonia.

CASE 6.—Hæmorrhage in mesentery; old adhesions, left apex; liver smaller than normal, spleen enlarged and diffluent; kidneys enlarged; slight chronic nephritis; blood in stomach; slight myocardial degeneration of heart.

CASE 7.—Mesenteric and pericardial hæmorrhages, liver two thirds normal size, nutmeg appearance, fibrous, spleen small and diffluent; small hæmorrhages *under kidney capsule and under pancreas*, blood in stomach.

CASE 8.—Parenchymatous degeneration of liver, also kidneys; superficial erosions of stomach.

Summary.

(1) Fifty-eight cases of delayed poisoning following administration of salvarsan and mercury were observed. Forty-seven of these showed symptoms referable to the liver—namely, jaundice, decreased digestive power, and liver atrophy. Eight of these were fatal (see Schedule) and at autopsy showed marked atrophy of the liver. Atrophy of the liver may be marked in cases which ultimately recover. This condition can be diagnosed by X rays.

(2) Dermatitis occurred in eight cases. Five were severe with marked exfoliation.

(3) Peripheral neuritis was observed in two cases.

(4) Albuminuria was present in over 50 per cent. of the cases. Œdema was found in two cases.

(5) The onset of the symptoms seldom occurred until five weeks after the administration of salvarsan had ceased.

(6) The earliest symptoms of salvarsan poisoning of the liver were—bile in the urine, albuminuria, loss of appetite, and jaundice. These symptoms should be looked for in all patients receiving salvarsan treatment, and on their appearance the administration of salvarsan should cease.

(7) By X ray examination atrophy of the liver may be diagnosed at an early stage.

(8) Where evidence of liver damage is present the diet should be reduced to a minimum.

(9) Dermatitis with atrophy of the liver occurred in one patient who received arsenic in the form of Fowler's solution, ɱ v.

(10) We believe these were cases of delayed arsenical poisoning.

We are indebted to Hon. Captain Lachlan Gilchrist, C.A.M.C., for much help in the examination of the liver by X rays; and to Captain James H. Howell, C.A.M.C., who was in charge of the jaundice wards at No. 16 Canadian General Hospital for several months, for his painstaking work on the cases and for keeping accurate records; and to Captain H. B. Hetherington, pathologist, No. 14 Canadian General Hospital, who performed the autopsies on our fatal cases.

THE AFTER-HISTORY OF 500 CONSECUTIVE TUBERCULOSIS DISPENSARY CASES.

BY F. GARLAND COLLINS, M.R.C.S.,
L.R.C.P. LOND., D P H.,
TUBERCULOSIS OFFICER FOR THE COUNTY BOROUGH OF WEST HAM
MEDICAL ADVISER TO THE WEST HAM INSURANCE COMMITTEE

THE following statistics were compiled after re examinations or investigations made during the latter end of the year 1919 and the beginning of 1920 of the cases recorded, which were first examined by me at the West Ham Tuberculosis Dispensary between the months of June and December, 1914. At that time (i.e., over five years ago), with the exception of patients sent for diagnosis by a *medical practitioner, only notified cases of* pulmonary tuberculosis and their contacts were dealt with at this institution.

Of the 500 cases examined, 238 were recently notified cases, 218 contacts of those cases, and 44 were "request" cases.

Notified cases.—Under this class were 153 males and 85 females; amongst this number were 18 cases which proved not to be tuberculous, including patients suffering from carcinoma of the œsophagus, carcinoma of the rectum, syphilis, diabetes, nephritis with œdema of the lungs. One very doubtful case left the district whilst undergoing observation at the dispensary.

Of the 219 positive cases, 95 were of type I, 67 of type II., and 57 of type III. (Types I, II, and III. correspond to the Turban Gerhardt classification.) Their after-history is shown in Table A —

TABLE A.—*Notified Cases.*

—	Arrested		Still under treatment		Dead		Left district untraced		Total	
	M	F	M	F	M	F	M	F	M	F.
Type I	26	14	9	8	11	3	13	11	59	36
Type II	5	0	7	4	19	12	15	5	45	22
Type III	0	0	3	1	28	16	6	3	37	20

In addition to dispensary or domiciliary treatment, 61 cases of type I., 48 of type II., and 23 of type III —in all 132 cases—were treated in sanatorium or hospital for periods varying from one month to one year, the average time being four months.

Contacts.—The majority of cases under this heading were children of school age, owing to the aversion of presumably healthy adults to attend for examination; chiefly the more "weakly" contacts were seen—i.e., those *who by reason of a cough* or some indefinite ailment induced the parent to suspect the possible presence of tuberculosis. Many

TABLE B.—*Contacts.*

—	Arrested		Still under *treatment*		Dead		Left district untraced		Total	
	M	F	M	F	M	F	M	F	M	F
Type I	7	7	2	3	1	2	3	2	13	14
Type II.	0	0	2	0	0	1	0	2	2	3
Type III	0	0	0	0	0	0	1	0	1	0
TABLE C.—"*Request*" *Cases.*										
Type I	5	1	2	0	2	1	0	1	9	3
Type II	0	1	0	0	2	2	0	1	2	4
Type III	0	0	0	0	4	0	0	0	4	0

more females than males made up this class, the former numbering 131 and the latter only 87, and yet of the 33 cases which proved to be definitely positive 19 were males and only 14 females, 27 being of type I., 5 of type II., and 1 of type III., with after-history as shown in Table B. Only 7 contacts received sanatorium treatment owing mainly to the absence of beds available for children.

"*Request*" *Cases.*—Of the 44 cases sent for diagnosis (25 males and 19 females), exactly one-half were found to be tuberculous, 12 being of type I., 6 of type II., and 4 of type III. Their after-history is shown in Table C. 13 of these cases received sanatorium treatment.

The positive cases from all three classes taken together show the approximate percentages given in Table D.

TABLE D.—*Combined List of Positive Cases.*

—	Arrested.	Under treatment.	Dead.	Left district untraced.	Received residential institutional treatment.
Type I.	44·7	18·0	15·0	22·3	53·0
Type II.	7·7	16·4	46·0	29·9	70·0
Type III.	0·0	6·4	77·4	16·2	42·0

The comparatively small percentage of type I. recorded as having received residential institutional treatment is due to the considerable number of children in this class for whom no institution was available; nearly all these children had dispensary treatment. Only a proportion of the adult cases tabulated as "arrested" have been verified by examination at the tuberculosis dispensary, but in practically every case the person is doing full-time work (industrial or household) and is not in need of medical treatment. All doubtful cases were kept under observation at the dispensary for varying periods before a definite diagnosis was made. Tuberculin was not used either as a diagnostic or curative agent, in any one of this series of cases. Periodical visits were paid to each case by the tuberculosis nurse to advise and encourage the best practicable hygienic measures in the home.

It is regrettable that such a considerable number of cases left the district and cannot be traced, as these would have somewhat modified the figures under the headings of arrested and dead, but the large migratory population of the industrial district from which the cases under consideration were drawn has been further augmented by war-time and post-war conditions.

Conclusions.

From the above analysis the following conclusions may be drawn:—

1. That pulmonary tuberculosis may be cured if treated in its early stages.
2. It is only the early case that derives any permanent benefit from sanatorium treatment (with rare exceptions); hence the futility of clogging the sanatoriums with the more advanced type of case.
3. Much more strenuous preventive measures should be adopted—e.g., additional suitable open-air schools and institutions for very advanced cases.
4. There is a sad lack of suitable institutions for the tuberculous child.
5. A certain percentage of positive adult contacts must escape detection while the disease is yet in its early stage.

Though of limited scope, I have ventured to publish these statistics in the hope that they may be of general interest and possibly prove of some utility.

Note.—Many reports recently published from various districts do not show such promising results as those above recorded. In this respect it may be of interest to note that this district was one of the first to adopt the medical inspection of school children and also the feeding of necessitous school children, in addition to being one in which the National Insurance Act has been in working order since 1912.

UNUSUAL CASES OF
INTESTINAL OBSTRUCTION.[1]

BY J. A. CAIRNS FORSYTH, M.SC., M.B., CH.B., F.R.C.S.,
SURGEON TO THE FRENCH HOSPITAL, AND SURGEON TO OUT-PATIENTS, ROYAL WATERLOO HOSPITAL FOR CHILDREN AND WOMEN, LONDON.

IN the treatment of intestinal obstruction, whether acute or chronic, the surgeon must always be prepared for surprises, for there is probably no other department in the whole of surgery where the diagnosis of the underlying cause is so difficult to foretell. This is easily understood when one considers the manifold possibilities for mischief within the abdomen. Apart from purely intrinsic causes, the bowel may be impeded in its functions by many conditions of extrinsic origin. To enumerate these would take a long time, and I do not propose discussing them, since after all the exact diagnosis of the causal factor, in the vast majority of cases of intestinal obstruction, is only of academic importance.

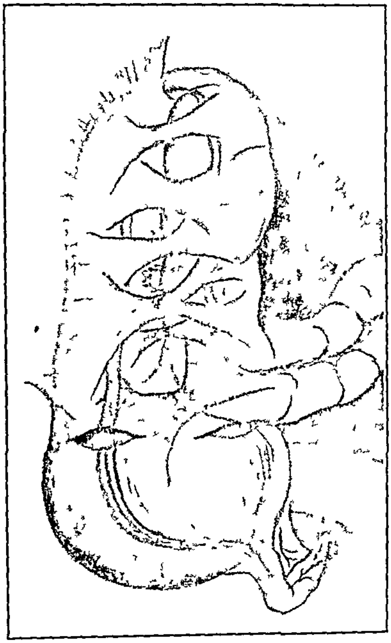
Some time ago I reviewed the numerous cases of intestinal obstruction that had come under my observation. They included many cases of exceptional interest, and, on summing up the series, it was rather surprising to find that in many instances the exact cause of the obstruction was only revealed at the operation. From the series I have chosen four cases to illustrate the difficulties with which one may have to contend, both in diagnosis and operative treatment. Two of the cases came under the care of Sir A. Mayo-Robson while I was his assistant, and I have to thank him for permission to record them. The other two occurred in my own practice.

CASE 1. *Acute angulation at the hepatic flexure from pericolitis; rupture of the tæniæ coli of the cæcum.*—The patient was a man, aged 62, who for some years had suffered from mucous colitis. On a recent visit to South Africa and Egypt he had been very ill from dysentery. When seen by Sir A. Mayo-Robson the patient complained of pain and discomfort in the lower abdomen, and stated that he was passing undigested food and mucus. The bowels were acting irregularly, and the patient noticed that with a morning action he had abdominal discomfort for the rest of the day. There was much less pain when the bowels acted in the evening, and he was always better when constipated. The patient came into a nursing home and the rectum and sigmoid were examined by the sigmoidoscope, but beyond undue redness and hypertrophy of the mucous membrane nothing abnormal was detected. Two days later he was suddenly seized with acute griping pain in the right iliac fossa, accompanied by marked distension in that region. There was some collapse, followed by slight rise of temperature and pulse rate, and in the evening by vomiting The distension was not relieved by enemata, so next morning operation was decided on Up till now the symptoms pointed more to appendicitis than to anything else When the abdomen was opened a remarkable condition was revealed (Fig 1) The cæcum was enormously distended and very inflamed and at its junction with the ascending colon there were two transverse slits, each about an inch long, involving the peritoneal coat and the anterior and internal tæniæ coli The circular fibres were intact, but the divided ends of the longitudinal bands were one third of an inch apart The abdominal incision was enlarged when the ascending and about 5 inches of the first part of the transverse colon were found bound together by adhesions so that the general appearance resembled that of a double barrelled shot gun These adhesions were confined to the wall of the gut, and did not extend to the peritoneal lining of the abdominal wall At the hepatic flexure extreme angulation had been produced The adhesions, some of which were very dense, were carefully separated, and the raw surfaces left were stitched over with fine chromic catgut When the fused portions of the bowel were ultimately freed a few reefs were taken in the transverse mesocolon so as to bring this part of the gut into better line The divided tæniæ coli were then sutured and the appendix, which was tortuous and somewhat distended, was removed The abdomen was then closed The patient made a good recovery, and obtained great relief from the operation Two and a half years later he was still passing some mucus in the stools, but the abdominal pain had quite disappeared

---

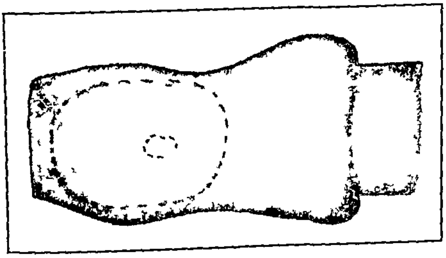
[1] Abstract of a lecture delivered before the Fellowship of Medicine on Jan. 28th, 1920.

FIG 1



CASE 1 —Acute angulation at the hepatic flexure from pericolitis Rupture of tæniæ coli

FIG 2

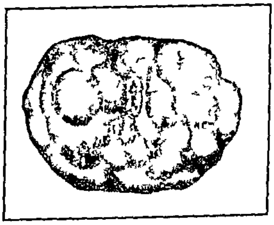


CASE 2 —Intussusception of the ileum secondary to polypus

Similar cases of obstruction of the large intestine have been recorded, notably by Jackson, Pilcher, Arbuthnot Lane, Mayo, and Gerster, but this case is probably unique in that, added to the acute angulation at the hepatic flexure, two of the three tæniæ coli were ruptured As these bands are shorter than the tube itself and keep the wall of the colon puckered, they were the first to give way during the acute distension of the cæcum If the obstruction had not been relieved by operation the partial rupture would, doubtless, have extended and probably become complete Much has been written on the ætiology of these constricting bands and adhesions, but this case seems to support Pilcher s view that they are the result of long continued or oft repeated mild infections of the peritoneal covering of the cæcum, colon, and appendix transmitted through the intestinal wall. Nowadays the extreme angulation would have been recognised by radiography after a bismuth meal but at the time when the patient was under treatment that diagnostic method was in its infancy

CASE 2 *Polypus of the ileum accompanied by chronic intussusception* —The patient was a woman of 65, who for some months had been subject to recurrent attacks of pain in the right lower quadrant of the abdomen These attacks had become more frequent and were usually accompanied by vomiting, abdominal distension, and constipation The vomit was always bile stained at first, but soon became foul, though never fæcal A swelling was ultimately detected in the hypogastrium, so operation was advised When the patient consulted Sir Arthur Mayo Robson the swelling was smooth and ovoid, and was about 3 inches long It was situated in the hypogastrium *to the right of the middle* line, and was freely mobile A diagnosis of tumour of the small intestine, probably malignant, was made At the operation the tumour was found in the ileum 6 inches from the ileo cæcal valve, but in addition there was a chronic intussusception immediately above (Fig 2) The intussusception was about 2 inches long and the various layers were much hypertrophied but not discoloured During reduction, which was easily performed, the tumour remained stationary it was not attached to the apex of the entering layer, as is generally the case Careful examination then revealed the fact that the growth was a polypus attached to the anterior wall of the ileum, midway between the mesenteric and free borders so the bowel was opened by a longitudinal incision and the tumour delivered through it It proved to be a large polypoid growth with a short narrow pedicle The

FIG 3

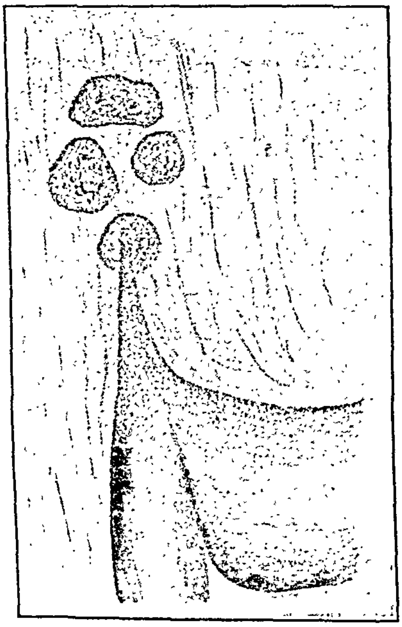


CASE 2 —Adenomatous polypus of the ileum latter was ligatured and divided and the bowel incision then closed by two continuous catgut sutures. The patient made a straightforward recovery and, happily for her, the polypus turned out to be of a simple character—an adenoma with a good deal of fibrous stroma. Fig. 3 shows the inner surface of the tumour with the pedicle. This surface was much lobulated, but the outer surface was smooth.

Single polypi of the small intestine are uncommon and in adults are often malignant. Not infrequently they produce intussusception, the polypus being found at the apex. In this case it was different. The intussusception was situated above the tumour and only the large size of the latter prevented the invagination from passing further down the bowel.

CASE 3. *Acute intestinal obstruction from traction diverticulum of the ileum.*—The patient was a man of 44, who had enjoyed good health until 12 years before, when he began to have recurrent attacks of abdominal pain, accompanied by vomiting. The pain, which was always of a griping nature, commenced behind the umbilicus and did not radiate. After a lapse of 12 to 18 hours there was profuse vomiting of bilious fluid. These attacks of sickness lasted for 24 hours and were sometimes relieved by taking a large dose of aperient. The griping pain usually subsided in three to four days. During each attack there was considerable abdominal distension. Ten years before I saw him (i.e., two years after the commencement of the recurrent attacks of pain and vomiting) the patient underwent an operation for acute appendicitis with abscess. The appendix was removed and the abscess drained. A weak scar resulted and the symptoms of pain and vomiting were not relieved; in fact, they became more frequent.

FIG. 4.



CASE 3.—Traction diverticulum of the ileum.

I first saw the patient with Dr. J. Henderson during one of these attacks, which had commenced 48 hours previously. Large quantities of bile-stained fluid were being vomited, and the abdominal pain was very severe. There was some general distension of the abdomen, and active peristalsis of coils of small intestine was plainly visible. I diagnosed obstruction of the small intestine, and advised that the abdomen be opened through the long weak appendectomy scar, for I considered that adhesions resulting from the appendicitis might be the cause of the trouble. The patient was removed to a nursing home and I operated the same afternoon. The weak scar was excised and the cæcum found attached to the anterior abdominal wall by some frail adhesions. It was, however, collapsed, so it was freed and search made for the obstructed part. The lower ileum, which was also collapsed, was rapidly examined from below upwards. About 6 feet from the ileocæcal valve the bowel was acutely kinked from a traction diverticulum. (Fig. 4.) The diverticulum was about 2 inches long and was adherent at its apex to one of four calcified lymphatic glands near the root of the mesentery. On freeing the diverticulum the kink immediately straightened out. The diverticulum appeared to be composed of all the coats of the intestinal wall, somewhat attenuated at the apex, but as it spontaneously contracted when it was freed I did not excise it, but contented myself with burying it by means of a purse-string suture. As the patient was very ill I did not spend time in removing the glands. A rapid repair of the weak abdominal scar was then performed and the abdomen closed. The patient obtained immediate relief from the operation and made an uninterrupted recovery.

Traction diverticula are of rare occurrence, but they have been found in all parts of the alimentary tract. They are small funnel-shaped pouches, produced by retraction of chronic localised peritonitis, by cicatrices in the wall of the intestine itself, or by inflammatory processes in adjacent organs. Adhesion of the bowel wall to a tuberculous lymphatic gland is one of the commonest causes. As Treves points out, mesenteric gland disease may lead to intestinal obstruction in various ways. The local peritonitis in the serous membrane covering the glands may produce adhesion of bowel or omentum, or may encourage the development of bands which may in turn cause intestinal strangulation. Or, again, the local peritonitis may lead to adhesions between the two limbs of a loop of intestine or between two remote parts of the intestinal tube. In Hilton Fagge's case the sigmoid was found adherent to the ileum and in the angle between the two attached portions of the gut was a caseous gland. In other cases the shrinkage of the mesentery after extensive gland disease was so pronounced and produced so much distortion as to cause obstruction of the adjacent bowel.

In the case which I have just described it is probable that the bowel became adherent to the gland early on in life, and that the diverticulum formation was a slow process produced by sagging of the intestinal loop. Obstructive symptoms appeared when the traction was sufficient to cause kinking of the gut.

CASE 4. *Strangulation of a loop of ileum by an adherent appendix epiploica of the sigmoid.*—The patient was a woman of 64, whom I saw in consultation with Dr. Edward Gregg. Two nights before she had been suddenly seized with severe pain in the lower abdomen, followed by profuse vomiting. Opium was given to relieve the pain and sickness. The patient was seen by Dr. Soltau Fenwick, who found a tense swelling in Douglas's pouch. He diagnosed pelvic peritonitis, and advised immediate operation. I saw the patient when she had been removed to a nursing home. The abdomen was rigid and tender but not distended. The tongue was furred. Pulse 120; temperature 100° F. On opening the abdomen by a subumbilical incision the pelvis was found filled with blood-stained fluid. This was quickly mopped up, when a coil of gangrenous small intestine presented in the wound. On passing the hand into the pelvis this gangrenous loop was found tied down by a band passing from the lower part of the sigmoid flexure to the bottom of the pouch of Douglas. The band was clamped, divided, and ligatured. As the proximal ligature was being passed, the band was examined and proved to be an attenuated appendix epiploica. The obstructed loop was now easily brought out through the incision. The ensnaring band had formed a marked constriction in the bowel wall and mesentery, but the gut above was not much distended, so I decided to excise the gangrenous loop and perform an end-to-end anastomosis. This was quickly done and the abdomen closed, a drainage-tube, passing down to Douglas's pouch, being left in the lower end of the wound. The patient made a splendid recovery, and the incision healed without any suppuration.

Many such cases of intestinal strangulation by appendices epiploicæ have been recorded. In Hulke's case an epiploic appendage from the sigmoid flexure was attached to the pelvic peritoneum near the right sciatic notch, and beneath the arcade so formed a loop of bowel had been strangulated. In another case, described by Holmes, an appendix epiploica formed a fatty fibrous ring around a loop of the lower ileum. As to what caused the adhesion of the appendage to the pelvic peritoneum in my case it is impossible to say. At first I thought I was dealing with a case of sacculitis of an epiploic appendage, but on examination there was no evidence of this. The appendage was long and fibrous, and did not appear to be patent. In sacculitis the appendage is usually hypertrophied and fatty, and often has a bulbous tip in which fæcal material becomes lodged and produces inflammation.

Harley-street, W.

A CASE OF COMBINED AORTIC AND MITRAL REGURGITATION

WHICH LASTED OVER 30 YEARS.

BY W. GORDON, M.D. CAMB., F.R.C.P. LOND.,
PHYSICIAN TO THE ROYAL DEVON AND EXETER HOSPITAL; PHYSICIAN TO THE WEST OF ENGLAND EYE INFIRMARY.

THE prognosis of aortic regurgitation has been variously stated. One well-known authority could not remember the survival of anyone suffering from it for 15 years, whilst other authorities, equally well known, recorded survivals for 20, 25, or 30 years. Such discrepancies seem only explicable as the outcome of local differences in the general expectation of life, showing themselves incidentally in sufferers from cardiac disease. A few years ago, with this possibility in mind, I undertook to investigate the differences in longevity in the registration districts of England, and found them to be remarkable. In Leeds, where the shorter survivals above mentioned were recorded, only 6 per cent. of the population reached the age of 75 and over, whereas in some of our Devonshire districts, such as Axminster and Crediton, 25 per cent. attained them.

Advantages of South-East Devon for Cardiac Cases.

I have repeatedly drawn attention to the advantages in cardiac cases of the crescent of country which reaches from Lyme Regis to the Start, an area which should be spoken of as South-East Devon. In this area acute rheumatism is rare, level reaches are available, general longevity is notable, whilst relative warmth and equability of climate, shelter from strong and cold winds, abundant sunshine, moderate rainfall and dryness of subsoil, combine to protect from lung and kidney complications. Probably the long survival of the case I am recording has owed something to these local advantages.

For whatever may be held to be the general prognosis in uncomplicated rheumatic aortic regurgitation, there is now a consensus of opinion that the outlook is made worse by the coexistence of mitral regurgitation. I do not know of any instance in the literature of such prolonged survival of a patient with both these lesions. It would be interesting to know if such cases have been observed, for it was formerly thought by some that the presence of coincident mitral regurgitation lessened, instead of increasing, the risks of aortic regurgitation, a view, however, which has been long discredited.

The Case Described.

K. E., aged 24, a very intelligent girl, came under my care as an out-patient at the Royal Devon and Exeter Hospital in January, 1891, with aortic and mitral regurgitation. Her heart disease dated, she said, from a severe attack of rheumatic fever two and a half years previously, which, together with a relapse, kept her in bed for 15 weeks. This had been her only attack of rheumatism, and, I should add, that it remained so.

On March 10th, 1892, she came into hospital with a bad gastric attack following "a cold." Her heart's apex beat was then noted to be in the fifth intercostal space in the left mammary line; there was a well-marked aortic regurgitant murmur, and a well-marked mitral regurgitant murmur conducted backwards towards the axilla; the lungs and kidneys were normal; she had slight œdema of the ankles. On May 11th she was made an out-patient again, and as such remained under my care for several years on and off; later, having improved in general condition, she was only seen by me at very long intervals until her final illness at the end of 1918.

On Jan. 22nd, 1908, I made this note: "There is still the same tight gripping pain, palpitation and dyspnœa, with occasional faintness, but not worse than 15 years ago." The pulse was 72, not "water-hammer." The apex beat was in the sixth space, 1 inch outside the left mammary line; the right edge of the cardiac dullness was at the right edge of the sternum; at the apex a systolic as well as diastolic murmur was audible, at the aortic cartilage a diastolic murmur only; the second sound was nowhere accentuated; all these points were observed in the erect position. It was, I think, just prior to this date that she had strained her heart in nursing her uncle, an old and heavy man.

On April 4th, 1910, I made a further note. She was "much better" than in 1908. Her pulse was 80, very little "water-hammer" in character, but now there was some visible arterial pulsation in the neck up to the ears. She had palpitation "pretty often," but pain was only brought on by exertion. The heart was evidently a little larger; the dullness in the erect position reached rightwards 1½ inches, and leftwards 4½ inches from the midsternal line, the apex beat still being in the sixth space; the diastolic murmur was heard over the aortic cartilage, down the sternum, and at the apex, as before.

In December, 1918, I was called to her late one night, when I found her desperately ill, cyanosed, and fighting for breath, with a greatly dilated and hypertrophied heart acting tumultuously. I endeavoured vainly to induce her to come into hospital, and in January she died. Her life had been by no means an idle one; except for the one considerable strain of nursing her uncle, already mentioned, it had been free from physical overstress, but it was full of active and valuable work.

Remarks.

Points to which I would draw attention are, that the case was uncomplicatedly rheumatic, dating from her single attack of acute rheumatism at 22; that she was otherwise healthy, with no lung or kidney complications; that, for the most part, her work was free from physical strain; that she successfully avoided further rheumatism; that the degree of aortic regurgitation was probably slight for a good many years, since "water-hammer" pulse and pulsation in the neck were absent for that time (remembering, however, the influence of coincident mitral regurgitation in modifying the pulse); that præcordial pain, palpitation, and dyspnœa on exertion, with occasional faintness, were present almost throughout; and that so long as 11 years before her death the apex beat, in the erect position, was already in the sixth space, and 1 inch outside the left mammary line.

THE PLATING OF SIMPLE FRACTURES.

BY F. D. SANER, F.R.C.S. ENG.,
SURGEON TO OUT-PATIENTS, EVELINA HOSPITAL FOR CHILDREN
LATE CONSULTANT SURGEON, ARMY OF THE RHINE.

SINCE there has been such a unique opportunity of testing the value of various methods of treatment of fractures during the past few years, I thought it might be of interest to record my own experience. It is more especially to the treatment of the simple fractures that I intend to confine my attention in this article, because of their greater frequency in civil life, and also because of the division of opinion still existing as to the best method of treatment.

In the first place I do not think it can be impressed too deeply on the student of surgery, or on the public at large, that a fracture is a difficult thing to deal with efficiently. The war has brought forward many new ideas on the treatment of fractures, and devices for the accurate splinting of limbs, and the work of Sinclair and others will be of lasting value, so that we may hope that in the future each fracture will be treated on its own merits, and that the era of the pattern splint, hopefully tied to a fractured limb, has passed.

Principles and Methods of Treatment.

In the treatment of any fracture there are two main principles that must be constantly kept in view: (1) that the bone must be restored, as far as possible to its original anatomical line; (2) that the joints above and below the site of fracture must have their complete function maintained.

It is true that very occasionally a good functional result may be obtained with an imperfect union of bone, but this in no way alters the main truth that the more perfect the reduction to the original anatomical line the more complete is the return of function. It must be remembered, also, that the restoration of the soft structures to their original position entirely depends on the reduction of the bone.

The two principles enunciated above are entirely interdependent. The movements of the neighbouring joints are often hindered by the misplacement of structures at the site of fracture, in the lower limb especially, where the bones bear the strain of the body-weight; any deviation of this strain, through faulty position of the bone, sooner or later causes changes in the joints. (Lane.)

There are two main methods of treatment for simple fractures:—

(1) The method of accurate splinting with extension, suspension, &c.[1]

(2) Operative treatment. Under the best circumstances a severe simple fracture presents a difficult problem. I believe that if the soft structures are destroyed sufficiently to allow of the effects of tension a complete reduction of the fragments may be obtained by non-operative measures. In order to achieve success the necessary equipment is essential, and much mechanical ingenuity and application may be required to deal with each fracture and overcome its particular difficulties. On the other hand, the effusion of blood into closed fascial compartments with little or no destruction of the soft parts offers an almost solid resistance, and renders immediate or even eventual reduction extremely difficult, and in cases where the displacement is severe, almost impossible. Therefore, in those cases of simple fracture, when an attempt at non-operative treatment has failed, operative treatment should be advised without delay. The operation of choice is that of plating, as evolved by Sir Arbuthnot Lane. I am advocating this method for the treatment of simple fractures. The question of plating compound fractures is an entirely different one, rarely arises in the early stages of their treatment and in the later stages only with full recognition of possible consequences.

Certain Objections Answered.

The main objections which have been brought against the operation of plating simple fractures, and have prevented its adoption as a routine method are: (1) that there are risks of sepsis; (2) that the plates and screws cause various after-effects and may have to be removed.

To avoid any risk of even the mildest infection, immediate or remote, the precautions insisted upon by Sir Arbuthnot Lane must be strictly adhered to by the surgeon and his assistants. The ultra care to be taken during the operation is absolutely essential to success. Apart from the actual technique which has been frequently described, there are one or two further considerations for the avoidance of infection which appear to me of importance.

The first, perhaps, is that of space. The initial incision should be of sufficient length to enable one to gain free access to the disturbed fragments and eventually to permit the introduction of a long plate. The muscles and periosteum are separated from the bone for the whole length of the incision. Lack of space renders manipulation with the large holding forceps and the insertion of the plate most difficult, with the consequence that the soft structures are apt to be lacerated, thus increasing the liability to continuous oozing afterwards and the risk of bacterial invasion.

The avoidance of post-operative bleeding and a hæmatoma which may leak through the wound and become mildly septic is most important. All bleeding points are at once seized by large hæmostat forceps, and these are left in situ till the end of the operation. It is rarely necessary to use ligatures, and they should be avoided as far as possible, as their absolute sterility is uncertain, and their application involves a definite risk of the fingers coming into contact with the wound. Bleeding tends to be most troublesome after operations on the femur. I believe it is better in these cases, after the insertion of the plate, to sew together the cut edges of the muscle and fascia by catgut sutures to assist in the arrest of bleeding, which sometimes is apt to continue.

When by manipulation the fractured ends of bone have been restored to their original position, the plate inserted should be of sufficient strength and length to secure the fragments firmly. There should never be any fear that shifting of position may occur afterwards. The plate is inserted with the idea that it shall remain in situ permanently, and it is no detriment when it has been properly applied and the operation has been absolutely aseptic. Occasionally, however, a plate has to be removed, and the most common reason for this is that it becomes loose. As a rule, this is due to faulty technique. The greatest care must be taken that the plate fits the bone accurately, so that the strain to maintain the fragments in position is divided equally between all the screws, and that no unequal strain is thrown on one or two; otherwise the screws that are strained will sooner or later become loose and the plate will separate from the bone. Another important detail is that the drill used is of suitable size, of a finer gauge than the screw. In this connexion I have found that, although more tiring to the surgeon, it is better to use a hand rather than a wheel drill as a more accurate idea of the density of the bone is obtained.

I do not agree with the statement sometimes made that the mere presence of the screws tends to cause rarefaction of the bone immediately around them If this were the case every screw and the plate would become loose, and they do not In the examination of a number of X ray photographs taken a considerable time (up to seven years) after the operation, it was impossible to detect any change round the majority of screws

---

[1] See article, British Journal of Surgery, vol. v., No. 19, 1918.

It is important that weight should not be borne on the limb until sound union has occurred, otherwise an undue strain is thrown on the plate and screws which tends to loosen them There is no doubt that callus formation is small in amount when the fragments are completely immobilised in apposition, consequently sufficient time should be allowed for complete union to occur It is impossible to state definitely when union should have occurred in any particular fracture, each case must be judged individually

All these details have been pointed out and insisted on by Sir Arbuthnot Lane, but they bear repetition, since they are so essential to a good result I have omitted deliberately, to discuss sepsis as a cause for removal of the plate I can only state that sepsis should not occur, and that in my own experience of a considerable number of cases I have not encountered it

In those cases where of necessity the plate is immediately subcutaneous, such as the clavicle and lower end of the fibula it may be advisable to remove the plate when it has fulfilled its function and union is complete Such plates are palpable under the skin, and are noticeable to the patient, and tenderness may be complained of from pressure of the clothes Although the removal of the plate entails a second operation this is a small price to pay for a good result

It is stated sometimes that the permanent presence of the plate causes the bone to become tender and to ache This has been attributed to the fixation of a rigid metal plate to a resilient bone There is no doubt that owing to altered circulation at the site of injury all fractures, recent or old, occasionally ache after exercise, or during changes in the weather, but I have not been convinced that the presence of a plate increases this, unless it has become loose or is subcutaneous Now and then, by the more highly educated or perhaps more sensitive patients, a request is made that the plate should be removed when its function is completed, as a knowledge of its existence gives them a feeling of abnormality It is the exception, however, for any further interference to be necessary when the original operation has been performed efficiently

After treatment

After the actual operation is finished I always place fractures of the femur and tibia in a Thomas hip splint, preferably jointed or slightly bent at the knee

The limb is completely immobilised in the splint by cross straps, and the foot, slightly dorsiflexed, is suspended from a metal archway or secured to a Sinclair foot piece The whole splint is then suspended in a frame by means of weights and pulleys This arrangement gives the patients a wide range of movement, and at quite an early stage enables them to be sat in a chair without disturbance to the limb, while from the nursing point of view these otherwise difficult cases are readily moved and lifted without fear of pain to the injured part There is, as a rule, fairly severe pain for the first 24 hours after the operation, but afterwards the patients are comfortable and do not become enfeebled through forced inactivity

Fractures of the upper limb after operation, are fixed on a Thomas arm splint with a movable joint at the elbow, or on some suitable wooden splint, but the latter, I think, should be confined to fractures of the lower forearm Whatever splint is used, the hand and fingers are allowed a certain freedom, so that some movements may be commenced about the second day

The fractured limb is not touched until the tenth day, when the wound is dressed and the skin clips are removed After this the cross straps are less firmly applied so as to allow of some movement in the splint At the beginning of the third week general massage of the whole limb is commenced (it is wise, perhaps, to avoid massaging over the actual wound for a little longer), and active and passive movements of the joints very gentle at first and gradually increasing, are begun For the purposes of massage the limb remains in the splint, the cross straps only being undone and afterwards refastened As a general rule by the end of the third week the lower limb may be left entirely free in the splint, so that greater activity may be encouraged and in cases of the upper limb the splint may be discarded for an increasing time each day In cases where there has been much comminution of the bone it may be thought wiser to delay much active movement, but usually massage can be commenced with safety in the third week, however severe the fracture has been

In cases of fracture of the lower limb it is possible almost at any stage after the wound is healed to supply some form of ambulatory splint which allows no strain whatever to fall on the site of fracture and permits the patient to walk with crutches My own feeling is however, that it is safer to wait until it is sure that union is strong The freedom of movement permitted in bed by this method of splinting and suspension counteracts to a great extent the necessity for getting the patients up, and an occasional accident may be caused through anxiety to allow the patient to walk Although it is practically always possible to permit cases of fracture of the upper limb or clavicle to get up at an earlier stage than those with fractures of the lower limb, judgment of the individual case must here again be exercised

In conclusion, I am indebted to the medical authorities of the Army of the Rhine for permission to publish this article I wish to thank also Sister J Strachan, Captain F Harlow, R A M C, and Captain H E Grey, R A M C, whose skilful assistance made these operations possible

[Skiagrams showing the excellent results obtained in 9 of the above cases were submitted —ED L]

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

EXTRACTION OF A SEWING NEEDLE FROM THE HEART.

By ZACHARY COPE, M D, M S LOND, F R C S ENG,
SURGEON TO THE BOLINGBROKE HOSPITAL SURGEON TO OUT PATIENTS ST MARY'S HOSPITAL

IN the case described below the slight evidence of pain caused by a needle in the cardiac substance was remarkable Though the cardiac muscle differs in structure from that of the intestine, yet it is involuntary and may resemble the intestinal musculature in absence of sensitiveness to tactile stimuli The sensitiveness to the stimuli of stretching due to distension of the enclosed cavity is common to both It was evident that the needle had travelled in the cardiac substance From a consideration of the point of entry into the chest wall and exit from the heart it must have moved about 2 inches, presumably through the substance of the right ventricle It almost appeared as if it were being extruded from the viscus It is an interesting speculation as to what would have been the course of the needle had it been thus extruded When the pleura was opened the heart fell away from the chest wall, and swayed violently to and fro with each respiratory movement. After about five minutes, however, the swaying lessened considerably, and the heart took up a position slightly nearer the chest wall. No disturbance was noted when the pericardium was gripped with a Spencer-Wells forceps.

Account of the Case.

A girl, 7 years old, was admitted to the Bolingbroke Hospital on March 2nd, 1920, with the history that a sewing-needle had been accidentally pushed into her chest. The place of entry was about an inch to the left of the sternum at the level of the upper border of the fourth costal cartilage. The house surgeon, under local anæsthesia, attempted to extract the needle; he cut down deep to the fibres of the pectoralis major and saw the extreme end of the needle in the depth of the wound. He was unable to grasp it, and the end completely disappeared whilst he was attempting to catch hold of it. He stated that it appeared to be sucked into the chest with each respiration.

I saw the child the same evening. Under the X rays the needle could be seen lying obliquely on a level with the fourth costal cartilage. It moved freely and completely with each heart beat, and it was clear that it was embedded in the heart. A general anæsthetic was administered by Major G. B. Lowe, and a slightly curved incision was made so as to expose the fourth and fifth left costal cartilages from which the muscular fibres were detached. About an inch of the fifth costal cartilage was removed, the portion resected being just internal to the vertical nipple line.

The pleura was opened, and for a time the swaying of the mediastinum and the cardiac pulsation made accurate observation impossible. The position of the needle had been observed from time to time during the operation by means of the fluorescent screen, and it was noteworthy that after the opening of the pleura the level of the shadow immediately became considerably lower than before. The mediastinal swaying gradually became less in extent, and by means of a good light it was possible to see about a quarter of an inch of the needle protruding near the left cardiac border. In order to steady the heart the pericardium was grasped by a Spencer-Wells forceps, and a similar forceps was passed into the pleural cavity so as to grasp and extract the needle. The parietal pleura could not be sewn, but the soft parts were brought together by two rows of catgut sutures, and the skin apposed by silkworm gut. The child stood the operation well, and the pulse-rate was neither irregular nor increased in rapidity at the end of the operation. The needle was 1⅝ inches in length.

When the child left hospital on March 22nd the wound was soundly healed, the left-sided pneumothorax was completely absorbed, and she felt perfectly well.

A DICEPHALOUS MONSTER.

BY M. Z. SHAFEÏ,
MEDICAL OFFICER, MANSOURA, EGYPT.

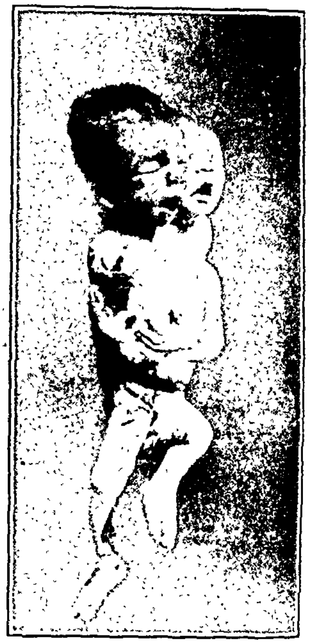
THE following case may be of some interest.

I was called at 7 A.M. on Feb. 24th to a woman said to have been in labour for three days. On arrival I found the patient (aged 20) in bed looking well. The history I got from her and from the midwife was that she had felt pain in the back and abdomen three days ago, and the midwife felt a head presentation. The head presented in the vagina for 24 hours. The midwife stated that she pulled the head as hard as she could but nothing more presented.

On examination I found a multiparous woman. Temperature normal, pulse 95, but not weak, and face not anxious. I felt a hard tumour in the right side of the true pelvis, and she complained of pain in the right thigh. Head and neck were outside the vagina, and the face was very congested. No pulsation felt in the facial artery, and no fœtal heart sounds heard. After evacuation of a full bladder and rectum I felt the shoulders filling the whole breadth of the pelvis. I tried in vain to move them to one side, but finding it impossible to pull down more than one arm, I decapitated the head, dislocated the arm at the shoulder, and did a version. On pulling the leg it disarticulated at the hip; then, helped by the pains, all the body came down and, to my astonishment, another head and neck was delivered, followed by the placenta. I douched the patient with lysol and gave her 10 c.cm. of antistreptococcal serum.

The condition of patient three days after was very good. She had no hæmorrhage and no rise of temperature, no tear in the perineum, and she promises, as I write, to continue a normal puerperium.

On examining the fœtus, I found it to be a male dicephalous monster, with two heads and necks, as seen in the appended photograph. The heads are fully developed. The monster was alive till six hours before delivery, as the patient felt its movements; one head was presenting. Although there is only one thorax, there are two vertebral columns, easily separable, reaching down to the sacrum. The two tracheas unite as one tube at the top of the thorax. There is one set of viscera in the thorax and abdomen. There is an imperforate anus and a phimosis. The testes are in the scrotum, which is bigger than normal and looks like two labia. The hair is well developed on both scalps. The length is 46 cm. and the weight 5 kg. The diagnosis was impossible and the treatment was circumstantial.



Dicephalous monster, male, with one thorax but two fully developed heads.

A CASE OF HYPOSPADIAS PERINEALIS.

BY S. CHELLIAH, M.B., C.M.,
ASSISTANT PATHOLOGIST, GENERAL HOSPITAL, COLOMBO.

THE patient here described had the anatomical characteristics of a man, but was brought up as a woman and was known by a feminine name, Punchi Nona. He was unmarried, and lived with and was supported by his sister's son. He was admitted into the female Diarrhœa Ward of the General Hospital, Colombo, on Nov. 24th, 1919, with anæmia, œdema of legs, and breathlessness of six months' duration, and died on Dec. 1st, at the age of 50, of uræmia due to chronic parenchymatous nephritis.

General appearance.—As shown in photo, with slight growth of hair on the chin and over the upper lip, larger growths in the armpits, slightly prominent *pomum Adami*, pyramidal growth of hair over the pubes, and deep and manly voice.

External genitalia.—The penis is small, imperfectly developed, looking not unlike a hypertrophied clitoris, adherent on either side to the scrotal integument, with no meatus urinarius. The scrotum is cleft, looking like the labia majora; the right half contains a testis, the left half is empty. The other testis was found in the left inguinal canal, together with a semi-solid blue mass close to it of the shape and size of the testis, due to phlebectasis of the veins of the pampiniform plexus. This mass was punctured by accident.

Urethra.—The lower wall of the urethra is defective as far back as the perineum, which condition, with the cleft scrotum, looks like the vulva. The sinus urogenitalis, thus presented, is wide and deep, about an inch in length, and opens directly into the bladder. The patient used to micturate in the squatting position.

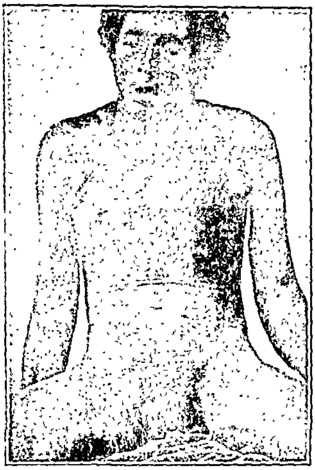


FIG. 1.—Pseudo-hermaphrodite, with male characteristics but brought up as a female.

Post-mortem examination.—The only pelvic organ was the bladder, the wall of which was thick, the mucous membrane slate-coloured and thrown into folds due to cystitis. The pelvis showed characteristics usually considered to indicate a male pelvis.

Microscopical examination.—The genital glands show the structure of the testis.

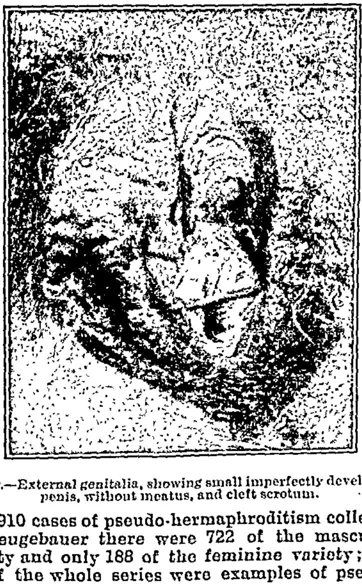

FIG. 2.—External genitalia, showing small imperfectly developed penis, without meatus, and cleft scrotum.

In 910 cases of pseudo-hermaphroditism collected by Neugebauer there were 722 of the masculine variety and only 188 of the feminine variety; and 613 of the whole series were examples of pseudohermaphroditismus masculinus externus.

Medical Societies.

PATHOLOGICAL SOCIETY OF GREAT BRITAIN AND IRELAND.

A MEETING of this society was held in the Institute of Pathology, Charing Cross Hospital, on March 26th and 27th, with Dr. W. W. C. TOPLEY in the chair.

Dr. E. H. KETTLE described the Histological Changes in Five Spleens which had been removed by operation in cases of "splenic anæmia." The anatomical changes were very diverse, one being of the Gaucher type, one, perhaps, early Hodgkin, one possibly tuberculous, and the other two indefinite. There is evidently much room for further work in differentiating the various types of splenomegaly associated with secondary anæmia.

Dr. W. MACADAM (Leeds) pointed out how the downgrowth of epidermis and the formation of cell nests in both tuberous and ulcerating forms of oriental sore (leishmaniasis) might give a remarkable resemblance to epithelioma.

Professor M. J. STEWART (Leeds) and Dr. J. A. C. FORSYTH described the formation of massive deposits of cholesterin in two cases of Long-standing Mastitis.

Dr. J. G. GREENFIELD showed an example of Multiple Neurofibromatosis with Tumours on the Cranial, Spinal, and Peripheral Nerves, with some beautiful drawings of the organs.

Dr. H. CHAMBERS, Dr. G. SCOTT, and Mr. S. RUSS described experiments showing that an accurately measured dose of X rays increased the susceptibility of rats to the implantation of a spontaneous rat carcinoma. They had succeeded by this means in bringing into cultivation a tumour which was not transplantable in normal animals. An unsuitable dose might increase resistance.

Mr. S. W. COLE (Cambridge) demonstrated improved methods of estimating sugar in blood, hydrochloric acid in gastric contents, and non-proteid nitrogen in blood.

Dr. J. O. W. BARRATT discussed some of the physical considerations underlying the formation of fibrin.

Dr. C. PRICE-JONES described remarkable diurnal variations in the size of red blood corpuscles, and said that on the average they were about 0·5 μ smaller on first waking in the morning than at midday. He showed that the variations were related to the reaction of the blood, that violent exercise caused swelling, and forced breathing shrinking.

Professor A. E. BOYCOTT pointed out the great rapidity with which the injection of lactic acid into the circulation was compensated, and questioned whether, in view of all the evidence that the blood persistently maintains its normal composition, it was likely that small changes of body reaction could be detected by blood examination.

Dr. A. G. GIBSON (Oxford) described a new streptothrix, pathogenic to monkeys, which he had isolated from the spleen removed during life from a case of acholuric jaundice.

A paper by Dr. J. W. MCLEOD (Leeds) on his experiences on the isolation of Pfeiffer's bacillus from cases of influenza gave rise to an animated discussion on the ætiological rôle of this organism, in which Drs. J. S. Dunn, W. E. Carnegie Dickson, F. W. Andrewes, R. Muir, S. L. Cummins, J. O. W. Barratt, W. d'Este Emery, J. Ritchie, C. J. Martin, J. A. Murray, H. R. Dean, J. M. Beattie, and W. W. C. Topley took part. Opinions were about equally divided as to whether the "influenza bacillus" could be considered to be the cause of "influenza" or not, and it was generally felt that the problem would be easier to solve if both the bacillus and the disease could be more closely delimited and defined.

Dr. TOPLEY and Dr. H. B. WEIR showed that identical lesions may be produced in the joints and hearts of rabbits by the intravenous inoculation of streptococci obtained from rheumatic and non-rheumatic cases.

Dr. A. F. S. SLADDEN (Swansea) showed two cases of Chorion-Epithelioma, one in a double uterus.

Dr. W. E. **CARNEGIE DICKSON** detailed the discovery of mites in the urine in two persons.

Dr. C. J. **MARTIN** discussed the Adjustment of the Reaction of Media, and pointed out that an appearance of spurious accuracy was liable to be given by some of the methods in current use owing to the failure to take into consideration the slow precipitation of tri-calcium phosphate in weakly alkaline solutions, the solubility of soft glass, the carbon dioxide in the air, and the temperature of incubation being substantially different from that of titration. Extreme precision being unnecessary and almost impracticable, he described a simple plan which gave consistent and satisfactory results.

Dr. **TOPLEY** and Dr. G. S. **WILSON** showed a Counting Chamber for Bacteria with a dark-ground condenser; and Mr. J. E. **BARNARD** gave a demonstration of some of the higher flights of microscopical technique.

Dr. J. A. **ARKWRIGHT** described cultures of Shiga's and other bacilli which apparently consisted of two components, differing markedly in their mode of growth and in their agglutinability by salt and specific sera. He left it uncertain whether the phenomena were the result of mutation or of selection.

Mr. N. C. **LAKE** showed the method of cultivating tissues in vitro and some results obtained.

Professor C. H. **BROWNING** and Dr. E. L. **KENNAWAY** gave the results of an analysis of over 2000 quantitative Wassermann tests, and proposed the following criteria: taking the amount of complement which gives complete hæmolysis in the negative control as 100, positive reactions are those which require more than 200 complement, negative those taking less than 150, the intermediate zone being regarded as neutral.

Dr. T. **TANIGUCHI** described a number of curious observations on heterogenetic antibodies—i.e., the sheep hæmolysins produced by injecting, for example, an emulsion of guinea-pig kidney into rabbits—and showed their specific relations to the tissue lipoids. He also pointed out that the sheep immune body which is sometimes present in human serum might give rise to an erroneously positive Wassermann test if an extract of guinea-pig heart was a component of the reaction.

Dr. F. **GRIFFITH** and Dr. W. M. **SCOTT** formulated proposals for improvements in the technique of the Wassermann reaction.

TUBERCULOSIS SOCIETY.

THE SYMPTOMATIC TREATMENT OF THE ADVANCED CASE.

AT a meeting of this society, held at the rooms of the Medical Society of London on March 29th, Dr. H. **BATTY SHAW** opened a discussion upon this subject. Nowadays, he said, owing to the establishment of tuberculosis dispensaries he did not see nearly so many advanced cases as previously. At present clinicians were engaged chiefly in discussions over doubtful cases, and the advanced case, which should be the chief care of the hospitals, was being turned away. In doing this the case was placed under that very unsatisfactory system called "domiciliary treatment." Consumption the result of secondary infection was one thing; advanced tuberculosis another. The treatment of consumption was at present futile, but this might to a great extent be prevented from occurring by prophylactic vaccine, inoculation against the secondary infection, combined with fresh air and hygiene. The tendency now was to concentrate upon the early case, but we should "put the clock back," and make the advanced case our special care. Hospitals were needed in each area where treatment and nursing could be provided and the case remain indefinitely. For those who did not need hospital treatment, domiciliary treatment on much improved lines should be provided. In dealing with special symptoms he did not think it advisable to keep the advanced case in bed indefinitely; many patients were better up and about. He allowed patients to eat what they liked, with, if possible, a preponderance of fat. The *appetite* could be improved by mixtures containing gentian and soda, *gentian and acid*, *phosphorus* and strychnine, and in some cases malt. Alcohol was not detrimental; as an appetiser it did good. *Cough* which disturbed *sleep* should be controlled, and he gave opium in large doses for this: small doses were useless. He recommended pil. ipecac. c. scilla gr. x.; heroin, $\frac{1}{8}$ gr. as being useful doses. Menthol in 10 to 20 per cent. solution used as a spray was often very valuable. The morning cough was made easier by a good drink of warm milk. For vomiting without cough he gave hydrocyanic acid, bismuth, and morphine. *Hæmoptysis* was treated with morphia, turpentine inhalations, and ice to suck. These, although not definite hæmostatics, gave the patients something to do and drew their attention from coughing. Calcium lactate was useless. Artificial pneumothorax was of value in some cases. *Sweating* was best controlled by limiting the bed-covering. Drugs lost their value after a few nights, and antipyretics only falsely encouraged patients to the belief that improvement had taken place. *Diarrhœa* might be controlled by sulphuric acid and opium, bismuth and opium, or perchloride of mercury and opium. *Laryngeal pain* was relieved by a cocaine lozenge, $\frac{1}{6}$ gr., before food, or by a spray containing 10 to 20 per cent. cocaine. Leduc's tube with orthoform was not very satisfactory, as the powder rarely reached the larynx. Injection of alcohol into the superior laryngeal nerve in very advanced cases had been practised with good results. *Pleurodynia* was best relieved by iodine and belladonna. *Cavities* could often be emptied by posture, but care should be exercised lest fresh areas of lung should become infected by inspiration. Anæsthetics were on this account dangerous. *Pneumothorax treatment*, although not curing the disease, was of great value in relieving symptoms. He preferred the open operation, which allowed exploration of the pleural cavity to be done. Two cases treated at University College Hospital by this method were shown.

Dr. J. J. **MACDONALD** and Dr. S. P. N. **PARSONS** gave short accounts of the methods of treatment being practised at the Brompton and University College Hospitals.

Dr. **HALLIDAY SUTHERLAND** emphasised the need for more hospitals for advanced cases. The cause of much failure in domiciliary treatment and the imperfect notification of the disease was the inadequate remuneration of the panel practitioners. He had used creasote up to 40 minims three times a day, also colloidal copper, but with no beneficial results. He considered the simple puncture method of pneumothorax quite adequate.

Dr. **JANE WALKER** said that advanced cases should be allowed to work, even though life was thereby shortened. She did not believe in keeping these cases for endless periods in bed. Alcohol in reasonable quantity should be allowed. Soda and hot water were of benefit to bring up sputum and posture helped in some cases. She gave horse serum on four consecutive mornings fasting, and it had proved beneficial in hæmoptysis.

Dr. F. **STANLEY TINKER** did not think sufficient attention was paid to other organisms present with the tubercle bacillus. A recent case in which streptococci had been found had made a remarkable recovery after 18 months in bed. Within a few weeks she was able to assume a normal life. He advocated better pathological facilities in each area, so that pathologist and clinician might work in coöperation.

Dr. W. **BRAND** described the discomforts which many patients in the advanced stages had to endure. Poverty should not be a bar to comfort, and we should rather parade common-sense than pure medicine. Even though we failed in the treatment of the advanced cases, we could, at any rate, make their lot easier.

Dr. A. **SANDISON** had found that many advanced cases were better for being up, and even fever in slight degree had vanished. This might be due to the mental effect. He had not found any benefit from chlorine and potassium iodide.

Dr. **JOHN SORLEY** said that in his experience a case of hæmoptysis either died before any help could be given, or else it did not require treatment. Small hæmoptyses were beneficial in promoting fibrosis.

Dr. **BATTY SHAW**, in reply, said that the operation shown for pneumothorax offered facilities for dividing adhesions, and in this way tended to increase the percentage successes. He did not advocate the treatment of mixed infection by vaccine, but inoculation as a prophylactic against its occurrence.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

A MEETING of this society was held at Sheffield on March 19th, when Mr. Miles H Phillips, the President, read short paper on

Unilateral Pelvo abdominal Pain due to Constriction of the Ureter.

The type of patient he had in mind, he said, complained of a ocalised and clearly described pelvic or pelvo abdominal pain, intensified by menstruation, for which the most careful pelvic examination, or even abdominal exploration, could find no satisfactory explanation. By a study of three ases he showed that constriction of a ureter by scar tissue r other band was a sufficiently likely cause to warrant xploration with the cystoscope and ureteral catheter. The first case had pain in right iliac and lumbar regions, commencing three days after hysterectomy for a fibroid which caused post partum hæmorrhage. Pain persisted although he general condition steadily improved. The bladder was examined a fortnight after operation, and the right ureter was seen to be acting less frequently, and ejecting a smaller stream of urine than the left. Further examinations later showed the right ureter apparently blocked. The abdomen was reopened and the affected ureter found dilated at the pelvic brim, and constricted about 1 inch from bladder by a ough fibrous cord containing vessels, and evidently resulting from tissue dragged inwards and included in the ligature round the right uterine artery at the previous operation. The division of the cord was followed by rapid recovery and no further pain. The second case was one of pain in left iliac and lumbar regions dating from confinement 17 years previously. There was menorrhagia and a pre menstrual exacerbation of pain No enlargement of left kidney; cervix deeply split on left side and firm scar in left fornix. The abdomen was opened and the left ureter found distended above a point opposite the cervix, where it plunged into a dense mass of scar tissue. The ureter was separated with difficulty, and hysterectomy was performed. The operation took place two years ago, and no pain had been experienced since. The third case was a single girl with pain in the right iliac fossa, commencing in 1914. Dilatation of cervix brought no relief. The right kidney was unduly mobile, and was fixed to fascia and muscles of loin 18 months later, but the pain continued. The abdomen was opened after a further interval of 18 months The uterus, appendages, and vermiform appendix were normal, and the right kidney well fixed There was extensive Jackson's membrane across the ascending colon, and strong peritoneal bands about the cæcum. The right ureter was bound down by a fibrous band, hardly more than a ridge of peritoneum, at a point 2 inches above pelvic brim. The band was divided and the patient completely relieved. In none of the cases was there any tangible enlargement of the kidney, but a hydronephrosis would probably have resulted had the obstruction not been removed. The symptoms complained of were those of early ureteric obstruction, and the fact that an increase in pain occurred before or during menstruation brought the cases under the care of the gynæcologist.

Dr. D. Dougal and Dr. J W. Bride (Manchester) communicated a paper on

Factors causing Abortion · an Analysis of 100 Cases.

The paper was based on a clinical and pathological examination of 100 consecutive cases of abortion admitted to the maternity department of St. Mary's Hospital, Manchester The authors pointed out that the work was in the nature of an experiment, and that a hundred cases formed too small a number on which to base authoritative results. They hoped, however, to continue the work along similar lines The following conclusions were arrived at as a result of the investigation. (1) Abortion occurs most commonly between the third and fourth months (2) It is comparatively uncommon in primiparæ; less than one fifth of the series belonged to this category. Most women who abort have borne previous full term children, and in most cases more than one. Frequent abortions in the same patient are uncommon and not necessarily due to syphilis (3) As regards the factors producing abortion, accidental and reflex causes account for 18 per cent ; general disease of the mother, 7 per cent ; disease or displacement of the mother's genital organs, 12 per cent ; and gross abnormalities of the fœtus, cord, or placenta other than those due to hæmorrhage and infarction, 6 per cent. They considered that the importance of syphilis as a cause of abortion had been somewhat exaggerated. The Wassermann reaction was positive in 12 cases, but in half of these some other abnormal condition was present which by itself might have produced the abortion. In only one case were clinical signs of syphilis present, and in no specimen could typical syphilitic changes or spirochætes be demonstrated. They estimated at not more than 10, and probably nearer 8, the percentage of cases in which syphilis produces abortion. The percentage of self induced cases was difficult to estimate, but was probably not less than 20 per cent. Ten patients in the series admitted that they had wilfully brought on abortion, and 8 of these employed lead pills for the purpose In 30 per cent of cases no cause could be assigned, and pathological investigation threw little additional light on the subject It would appear, however, that the mother was at fault in the great majority of cases as the result of some diseased condition, whether of an organic nature or merely an increased irritability of the centres which preside over the expulsive action of the uterus.

ROYAL MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.

AT a meeting of the society held on March 19th, Mr. A. Ernest Maylard, the President, being in the chair, Dr. Wm. Rankin reported (*a*) two cases of Ruptured Jejunum. (1) A man, aged 19, who had fallen from a scaffold, landing on his abdomen, presented no external abrasion, but was collapsed and in great pain, with a very rigid abdomen. Operation a few hours later revealed an almost completely transverse tear of the jejunum, which was sutured. Patient was dismissed well on twenty second day. (2) A man who, having fallen down the hold of a ship and struck some beams in falling, presented a fracture of the crest of the ilium and blood in the urine At operation seven hours later two tears were found in upper part of jejunum, which were sutured. Patient was seriously ill for four days, but ultimately made an excellent recovery. (*b*) A case of Diaphragmatic Hernia operated on through the pleural cavity. The patient, a boy aged 8, was run over by a motor van, and presented bruising and a rigid abdomen. An exploratory incision above the umbilicus showed that the spleen and greater part of stomach had been displaced into the left pleural cavity through a large tear in the diaphragm The abdominal wound was closed and an osteoplastic flap, including portions of two ribs in the axillary and posterior regions of the left thorax, was turned up to give free access to the pleural cavity. Through this the organs were replaced without difficulty and the tear in the diaphragm sutured. The patient was dismissed well after 25 days, and when seen at the meeting (5½ years later) showed no abnormality of the chest or lungs.

Dr. G. Herbert Clark reported "An Undescribed Condition of Infancy and its Treatment" The condition had been identified in two children, one of whom was now normal and the other slowly becoming so The outstanding symptoms were idiocy, depression, fibrillary twitchings in the muscles, jerking movements of the limbs, convulsions, and inability to balance. The first patient had been apparently normal till the age of 4 months, when the fits and startings began. When first seen in 1910, at the age of 15 months, he had a well formed and plump body, a large head with open anterior fontanelle, an abnormal staring, and apparently unseeing condition of the eyes, and presented all the symptoms mentioned above. Examination of the electrical reactions gave inconclusive results. Neither carpo pedal spasms, Trousseau's nor Chvostek's phenomena were ever present As the symptoms seemed to resemble those produced in animals by removal of the parathyroids, the effect was tried of feeding with thyroid gland tablets containing parathyroid as an impurity. On a dose of ½ gr. twice daily the child improved rapidly, was free from fits and twitchings after three weeks, and is now absolutely normal. The tablets were continued for six months and then gradually stopped. The second child was a girl, who had been fairly normal till about a year old, and then began to have twitchings, startings, and convulsions, with apparent indifference to surroundings and growing depression When first seen in September, 1919, she was 2½ years old, well formed, plump, with satisfactory dentition, but the anterior fontanelle not quite closed. Symptoms were similar to those in the other case. On Oct. 16th the child was put on parathyroid tablets 1/10th gr. twice daily; fits, startings, and twitchings at once began to diminish and quite ceased by Oct 24th. The child improved in alertness, took notice of her surroundings, played with toys, and could sit up and even stand. On Oct 27th parathyroid treatment was discontinued, and the fits, which had been absent for five days, at once recurred with violence By the end of the week the child was rapidly falling back into the state on admission. To ascertain the effect of thyroid gland, this was given for a week in small doses (1/8 gr. t i d) so as to exclude any effect of possibly present parathyroid, but without benefit. On Nov. 10th parathyroid was resumed, and by the end of a week most marked improvement had taken place. This was maintained, and when seen on March 9th the child was running about, playing, and trying to talk. The condition described was illustrated by numerous photographs of both children taken before, during, and after treatment —Dr. W. H. Brown made a "Plea for the Early Recognition of Syphilis."

Dr. W. E. **CARNEGIE DICKSON** detailed the discovery of mites in the urine in two persons.

Dr. C. J. **MARTIN** discussed the Adjustment of the Reaction of Media, and pointed out that an appearance of spurious accuracy was liable to be given by some of the methods in current use owing to the failure to take into consideration the slow precipitation of tri-calcium phosphate in weakly alkaline solutions, the solubility of soft glass, the carbon dioxide in the air, and the temperature of incubation being substantially different from that of titration. Extreme precision being unnecessary and almost impracticable, he described a simple plan which gave consistent and satisfactory results.

Dr. **TOPLEY** and Dr. G. S. **WILSON** showed a Counting Chamber for Bacteria with a dark-ground condenser; and Mr. J. E. **BARNARD** gave a demonstration of some of the higher flights of microscopical technique.

Dr. J. A. **ARKWRIGHT** described cultures of Shiga's and other bacilli which apparently consisted of two components, differing markedly in their mode of growth and in their agglutinability by salt and specific sera. He left it uncertain whether the phenomena were the result of mutation or of selection.

Mr. N. C. **LAKE** showed the method of cultivating tissues in vitro and some results obtained.

Professor C. H. **BROWNING** and Dr. E. L. **KENNAWAY** gave the results of an analysis of over 2000 quantitative Wassermann tests, and proposed the following criteria: taking the amount of complement which gives complete hæmolysis in the negative control as 100, positive reactions are those which require more than 200 complement, negative those taking less than 150, the intermediate zone being regarded as neutral.

Dr. T. **TANIGUCHI** described a number of curious observations on heterogenetic antibodies—i.e., the sheep hæmolysins produced by injecting, for example, an emulsion of guinea-pig kidney into rabbits—and showed their specific relations to the tissue lipoids. He also pointed out that the sheep immune body which is sometimes present in human serum might give rise to an erroneously positive Wassermann test if an extract of guinea-pig heart was a component of the reaction.

Dr. F. **GRIFFITH** and Dr. W. M. **SCOTT** formulated proposals for improvements in the technique of the Wassermann reaction.

TUBERCULOSIS SOCIETY.

THE SYMPTOMATIC TREATMENT OF THE ADVANCED CASE.

AT a meeting of this society, held at the rooms of the Medical Society of London on March 29th, Dr. H. **BATTY SHAW** opened a discussion upon this subject. Nowadays, he said, owing to the establishment of tuberculosis dispensaries he did not see nearly so many advanced cases as previously. At present clinicians were engaged chiefly in discussions over doubtful cases, and the advanced case, which should be the chief care of the hospitals, was being turned away. In doing this the case was placed under that very unsatisfactory system called "domiciliary treatment." Consumption the result of secondary infection was one thing; advanced tuberculosis another. The treatment of consumption was at present futile, but this might to a great extent be prevented from occurring by prophylactic vaccine, inoculation against the secondary infection, combined with fresh air and hygiene. The tendency now was to concentrate upon the early case, but we should "put the clock back," and make the advanced case our special care. Hospitals were needed in each area where treatment and nursing could be provided and the case remain indefinitely. For those who did not need hospital treatment, domiciliary treatment on much improved lines should be provided. In dealing with special symptoms he did not think it advisable to keep the advanced case in bed indefinitely; many patients were better up and about. He allowed patients to eat what they liked, with, if possible, a preponderance of fat. The *appetite* could be improved by mixtures containing gentian and soda, gentian and acid, phosphorus and strychnine, and in some cases malt. Alcohol was not detrimental; as an appetiser it did good. *Cough* which disturbed *sleep* should be controlled, and he gave opium in large doses for this: small doses were useless. He recommended pil. ipecac. c. scilla gr. x.; heroin, $\frac{1}{6}$ gr. as being useful doses. Menthol in 10 to 20 per cent. solution used as a spray was often very valuable. The morning cough was made easier by a good drink of warm milk. For vomiting without cough he gave hydrocyanic acid, bismuth, and morphine. *Hæmoptysis* was treated with morphia, turpentine inhalations, and ice to suck. These, although not definite hæmostatics, gave the patients something to do and drew their attention from coughing. Calcium lactate was useless. Artificial pneumothorax was of value in some cases. *Sweating* was best controlled by limiting the bed-covering. Drugs lost their value after a few nights, and antipyretics only falsely encouraged patients to the belief that improvement had taken place. *Diarrhœa* might be controlled by sulphuric acid and opium, bismuth and opium, or perchloride of mercury and opium. *Laryngeal pain* was relieved by a cocaine lozenge, $\frac{1}{6}$ gr., before food, or by a spray containing 10 to 20 per cent. cocaine. Leduc's tube with orthoform was not very satisfactory, as the powder rarely reached the larynx. Injection of alcohol into the superior laryngeal nerve in very advanced cases had been practised with good results. *Pleurodynia* was best relieved by iodine and belladonna. *Cavities* could often be emptied by posture, but care should be exercised lest fresh areas of lung should become infected by inspiration. Anæsthetics were on this account dangerous. *Pneumothorax treatment*, although not curing the disease, was of great value in relieving symptoms. He preferred the open operation, which allowed exploration of the pleural cavity to be done. Two cases treated at University College Hospital by this method were shown.

Dr. J. J. **MACDONALD** and Dr. S. P. N. **PARSONS** gave short accounts of the methods of treatment being practised at the Brompton and University College Hospitals.

Dr. **HALLIDAY SUTHERLAND** emphasised the need for more hospitals for advanced cases. The cause of much failure in domiciliary treatment and the imperfect notification of the disease was the inadequate remuneration of the panel practitioners. He had used creasote up to 40 minims three times a day, also colloidal copper, but with no beneficial results. He considered the simple puncture method of pneumothorax quite adequate.

Dr. **JANE WALKER** said that advanced cases should be allowed to work, even though life was thereby shortened. She did not believe in keeping these cases for endless periods in bed. Alcohol in reasonable quantity should be allowed. Soda and hot water were of benefit to bring up sputum and posture helped in some cases. She gave horse serum on four consecutive mornings fasting, and it had proved beneficial in hæmoptysis.

Dr. F. **STANLEY TINKER** did not think sufficient attention was paid to other organisms present with the tubercle bacillus. A recent case in which streptococci had been found had made a remarkable recovery after 18 months in bed. Within a few weeks she was able to assume a normal life. He advocated better pathological facilities in each area, so that pathologist and clinician might work in coöperation.

Dr. W. **BRAND** described the discomforts which many patients in the advanced stages had to endure. Poverty should not be a bar to comfort, and we should rather parade common-sense than pure medicine. Even though we failed in the treatment of the advanced cases, we could, at any rate, make their lot easier.

Dr. A. **SANDISON** had found that many advanced cases were better for being up, and even fever in slight degree had vanished. This might be due to the mental effect. He had not found any benefit from chlorine and potassium iodide.

Dr. **JOHN SORLEY** said that in his experience a case of hæmoptysis either died before any help could be given, or else it did not require treatment. Small hæmoptyses were beneficial in promoting fibrosis.

Dr. **BATTY SHAW**, in reply, said that the operation shown for pneumothorax offered facilities for dividing adhesions, and in this way tended to increase the percentage successes. He did not advocate the treatment of mixed infection by vaccine, but inoculation as a prophylactic against its occurrence.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

A MEETING of this society was held at Sheffield on March 19th when Mr Miles H Phillips, the President, read a short paper on

Unilateral Pelvo abdominal Pain due to Constriction of the Ureter

The type of patient he had in mind, he said, complained of a localised and clearly described pelvic or pelvo abdominal pain, intensified by menstruation, for which the most careful pelvic examination, or even abdominal exploration, could find no satisfactory explanation By a study of three cases he showed that constriction of a ureter by scar tissue or other band was a sufficiently likely cause to warrant exploration with the cystoscope and ureteral catheter The first case had pain in right iliac and lumbar regions commencing three days after hysterectomy for a fibroid which caused post partum hæmorrhage Pain persisted although the general condition steadily improved The bladder was examined a fortnight after operation and the right ureter was seen to be acting less frequently, and ejecting a smaller stream of urine than the left Further examinations later showed the right ureter apparently blocked The abdomen was reopened and the affected ureter found dilated at the pelvic brim, and constricted about 1 inch from bladder by a tough fibrous cord containing vessels, and evidently resulting from tissue dragged inwards and included in the ligature round the right uterine artery at the previous operation The division of the cord was followed by rapid recovery and no further pain The second case was one of pain in left iliac and lumbar regions dating from confinement 17 years previously There was menorrhagia and a pre menstrual exacerbation of pain No enlargement of left kidney, cervix deeply split on left side and firm scar in left fornix The abdomen was opened and the left ureter found distended above a point opposite the cervix, where it plunged into a dense mass of scar tissue The ureter was separated with difficulty, and hysterectomy was performed The operation took place two years ago, and no pain had been experienced since The third case was a single girl with pain in the right iliac fossa commencing in 1914 Dilatation of cervix brought no relief The right kidney was unduly mobile and was fixed to fascia and muscles of loin 18 months later, but the pain continued The abdomen was opened after a further interval of 18 months The uterus appendages, and vermiform appendix were normal, and the right kidney well fixed There was extensive Jackson's membrane across the ascending colon, and strong peritoneal bands about the cæcum The right ureter was bound down by a fibrous band, hardly more than a ridge of peritoneum at a point 2 inches above pelvic brim The band was divided and the patient completely relieved In none of the cases was there any tangible enlargement of the kidney, but a hydronephrosis would probably have resulted had the obstruction not been removed The symptoms complained of were those of early ureteric obstruction and the fact that an increase in pain occurred before or during menstruation brought the cases under the care of the gynæcologist

Dr D Dougal and Dr J W Bride (Manchester) communicated a paper on

Factors causing Abortion an Analysis of 100 Cases

The paper was based on a clinical and pathological examination of 100 consecutive cases of abortion admitted to the maternity department of St Mary's Hospital, Manchester The authors pointed out that the work was in the nature of an experiment and that a hundred cases formed too small a number on which to base authoritative results They hoped, however, to continue the work along similar lines The following conclusions were arrived at as a result of the investigation (1) Abortion occurs most commonly between the third and fourth months (2) It is comparatively uncommon in primiparæ, less than one fifth of the series belonged to this category Most women who abort have borne previous full term children and in most cases more than one Frequent abortions in the same patient are uncommon and not necessarily due to syphilis (3) As regards the factors producing abortion, accidental and reflex causes account for 18 per cent, general disease of the mother, 7 per cent, disease or displacement of the mother's genital organs 12 per cent, and gross abnormalities of the fœtus cord, or placenta other than those due to hæmorrhage and infarction 6 per cent They considered that the importance of syphilis as a cause of abortion had been somewhat exaggerated The Wassermann reaction was positive in 12 cases but in half of these some other abnormal condition was present which by itself might have produced the abortion In only one case were clinical signs of syphilis present, and in no specimen could typical syphilitic changes or spirochætes be demonstrated They estimated at not more than 10 and probably nearer 8 the percentage of cases in which syphilis produces abortion The percentage of self induced cases was difficult to estimate, but was probably not less than 20 per cent Ten patients in the series admitted that they had wilfully brought on abortion, and 8 of these employed lead pills for the purpose In 30 per cent of cases no cause could be assigned, and pathological investigation threw little additional light on the subject It would appear however, that the mother was at fault in the great majority of cases as the result of some diseased condition, whether of an organic nature or merely an increased irritability of the centres which preside over the expulsive action of the uterus

ROYAL MEDICO CHIRURGICAL SOCIETY OF GLASGOW.

AT a meeting of the society held on March 19th, Mr A Ernest Maylard, the President, being in the chair, Dr Wm Rankin reported (*a*) two cases of Ruptured Jejunum (1) A man, aged 19, who had fallen from a scaffold, landing on his abdomen, presented no external abrasion but was collapsed and in great pain, with a very rigid abdomen Operation a few hours later revealed an almost completely transverse tear of the jejunum, which was sutured Patient was dismissed well on twenty second day (2) A man who, having fallen down the hold of a ship and struck some beams in falling, presented a fracture of the crest of the ilium and blood in the urine At operation seven hours later two tears were found in upper part of jejunum, which were sutured Patient was seriously ill for four days but ultimately made an excellent recovery (*b*) A case of Diaphragmatic Hernia operated on through the pleural cavity The patient, a boy aged 8, was run over by a motor van, and presented bruising and a rigid abdomen An exploratory incision above the umbilicus showed that the spleen and greater part of stomach had been displaced into the left pleural cavity through a large tear in the diaphragm The abdominal wound was closed and an osteoplastic flap including portions of two ribs in the axillary and posterior regions of the left thorax was turned up to give free access to the pleural cavity Through this the organs were replaced without difficulty and the tear in the diaphragm sutured The patient was dismissed well after 25 days and when seen at the meeting (5½ years later) showed no abnormality of the chest or lungs

Dr G Herbert Clark reported "An Undescribed Condition of Infancy and its Treatment" The condition had been identified in two children, one of whom was now normal and the other slowly becoming so The outstanding symptoms were idiocy, depression, fibrillary twitchings in the muscles, jerking movements of the limbs, convulsions and inability to balance The first patient had been apparently normal till the age of 4 months when the fits and startings began When first seen in 1910, at the age of 15 months, he had a well formed and plump body, a large head with open anterior fontanelle, an abnormal staring, and apparently unseeing condition of the eyes and presented all the symptoms mentioned above Examination of the electrical reactions gave inconclusive results Neither carpo pedal spasms, Trousseau's nor Chvostek s phenomena were ever present As the symptoms seemed to resemble those produced in animals by removal of the parathyroids the effect was tried of feeding with thyroid gland tablets containing parathyroid as an impurity On a dose of ½ gr twice daily the child improved rapidly, was free from fits and twitchings after three weeks, and is now absolutely normal The tablets were continued for six months and then gradually stopped The second child was a girl, who had been fairly normal till about a year old, and then began to have twitchings startings and convulsions with apparent indifference to surroundings and growing depression When first seen in September, 1919 she was 2½ years old, well formed, plump, with satisfactory dentition, but the anterior fontanelle not quite closed Symptoms were similar to those in the other case On Oct 16th the child was put on parathyroid tablets 1/10th gr twice daily fits, startings, and twitchings at once began to diminish and quite ceased by Oct 24th The child improved in alertness took notice of her surroundings played with toys, and could sit up and even stand On Oct 27th parathyroid treatment was discontinued, and the fits, which had been absent for five days at once recurred with violence By the end of the week the child was rapidly falling back into the state on admission To ascertain the effect of thyroid gland, this was given for a week in small doses (1/8 gr t i d) so as to exclude any effect of possibly present parathyroid, but without benefit On Nov 10th parathyroid was resumed and by the end of a week most marked improvement had taken place This was maintained, and when seen on March 9th the child was running about, playing, and trying to talk The condition described was illustrated by numerous photographs of both children taken before during, and after treatment —Dr W H Brown made a "Plea for the Early Recognition of Syphilis"

Reviews and Notices of Books.

VITAL STATISTICS.

An Introduction to the Science of Demography. By GEORGE CHANDLER WHIPPLE, Professor of Sanitary Engineering in Harvard University; Member of the Public Health Council, Massachusetts State Department of Health. London: Chapman and Hall, Ltd. New York: John Wiley and Sons, Inc. 1919. Pp. 517. 18s. 6*d.*

THE appearance of an American handbook on vital statistics is a sign of the increasing importance attached to this subject in the United States. It is a commonplace in the history of public health in England that its progress has, in very large measure, been impelled and guided, as well as measured, by our national death returns, under the inspiring influence of William Farr and his successors. But in the United States the path of the vital statistician is strewn with difficulties. Thus, quoting from Mr. Whipple, not only are state "governments too easy-going to insist on the enforcement of such laws as exist," but laws are inadequate in most states, and the registration returns are made by a large number of clergy and laymen, "not properly instructed, not interested in the proceedings, and not always understanding the law." Worst of all, the people themselves "do not appreciate the personal importance of having the most important events in their lives made matters of public record." This defect is most marked in regard to birth registration. Thus in Cambridge, Mass., the seat of Harvard University, the birth records are so incomplete "that annually a house-to-house canvas is made to ascertain the births for the year." Mr. Whipple adds: "This is a disgraceful admission of incompetence on the part of the local registrar and of the negligence of all concerned." During last year the Children's Bureau of Washington, a department of the Labour Ministry, initiated an educational "drive" by leaflets, &c., urging everyone to register the birth of their children. Meanwhile, in a majority of states the registration of births is so imperfect as to render it impracticable to determine whether progress is being made in the saving of child life, to compare different areas with each other, or to determine the exact amount of loss of maternal life in childbearing in terms of the exposure to risk. In stating these facts it must always be borne in mind that a large proportion of the population of the states is alien, among whom the difficulties both of registration and sanitation are exceptionally great.

Morbidity statistics are incomplete to a very varying degree. It is interesting to note that in most states this duty is imposed on physicians, no fee being paid for the certificate. As regards death returns, in 1918 nearly 78 per cent. of the total population of the United States was in "registration areas," which for this purpose means states and cities in which satisfactory registration laws are being effectively enforced, and where there is reason to believe that more than 90 per cent. of all deaths are being registered; a standard which must still be regarded as unsatisfactory.

It is evident that in dealing with such relatively unsatisfactory material as the above facts imply Mr. Whipple's task is made more difficult than it would be under more favourable conditions. Fortunately, however, he deals rather with methods than with an analysis of statistical or epidemiological results, and on these lines the elegant volume which is before us contains much of general interest, and of special interest to all who have to deal practically with the analysis of vital statistics. The first chapter gives a short sketch of demography; in the second the elements of statistical arithmetic are stated. In this chapter we welcome the statement: "It is pitiful to see the energy and time wasted by some health officers in using unnecessary decimals in performing long division operations"; and we may add the further expression of regret that so many health officers, especially those dealing with scanty data, insist on carrying the calculations of rates to two or even three places of decimals, thus obtaining a completely fictitious appearance of extreme accuracy. In the third chapter statistical graphs are dealt with, and in the fourth enumeration and registration, on which some comments have already been made. The fifth chapter, dealing with estimations of population, has a useful appendix giving a list of all cities with a population of 25,000 or more in 1910. It is interesting to note that in 1850 three-fourths of the population of the United States was native-born, while this can only be said now of about one-half.

In Chapter V., dealing with general death-rates, the question is raised as to inclusion of the deaths of residents who die away from home. Mr. Whipple approves of the action of the American Bureau of the Census in taking the geographical point of view. Apparently he is not acquainted with the method of correction adopted in Great Britain, which gives a more useful and more nearly accurate result for the comparative purposes of vital statisticians, but perhaps such a method would be inapplicable for the present in the United States. Each state is self-contained in respect of its vital statistics, as in other matters; and this means vast differences in efficiency and completeness of registration. There is much of interest in this chapter; the following remark, even though it needs to be slightly safeguarded, gives food for thought:—

> "Unless public health officials learn how to view general death-rates in a proper light—a good way being not to view them at all—they may be surprised and discouraged some day to find that the death-rate is rising."

In another chapter, dealing with specific death-rates, Mr. Whipple discusses the various methods of securing standardised death-rates; and in Chapter VIII. the International list of causes of death is printed, as well as a useful list of occupations.

In subsequent chapters tuberculosis statistics are discussed, the statistics of diphtheria, of typhoid fever, and of cancer. Under the heading of cancer the author quotes the original paper by King and Newsholme in the Proceedings of the Royal Society for 1893, which showed that the balance of evidence was in favour of the view that the apparent increase was merely statistical, a view which has since been strikingly confirmed. Evidently, however, he is not acquainted with the even more recent study of the subject by Dr. T. H. C. Stevenson, which throws additional light on the problem, and necessitates a reconsideration of earlier conclusions.

In dealing with infant mortality statistics the author gives a number of tables as to the relation between infant mortality and type of house, sleeping rooms, ventilation, attendance at birth, education of foreign mothers, age of mother, method of feeding, household duties, and earnings of fathers. He remarks that the vital statistician must train himself to analyse his statistics. In the tables, the subjects of which are enumerated above, there is preliminary analysis galore but no satisfactory teaching; the author has missed an opportunity in not emphasising the point in regard to each of these tables, that the variations in infant mortality may or may not be significant, and what we require to know is that in the compared groups other things are practically equal and the groups really comparable. Probability is discussed in Chapter XII., and correlation and life tables in the next two chapters. There is much useful matter in these chapters, but we doubt whether this information will be directly valuable to health officials. These chapters, and the chapters on the use of medical and demological statistics, strike us as the least satisfactory in the book; their worth would have been greatly increased had the author secured the active coöperation of a medical officer of health who is familiar with the statistical difficulties of his medical work and the way out of them. There are useful appendices to the work, dealing with references, a model law of morbidity reports, and of registration of births and deaths. Finally, there is a table of logarithms.

The book will be found helpful by health officials and by others interested in vital statistics. It is singularly free from real errors, and we trust that it will stimulate the extension and perfection of birth and death registration throughout the United States.

HERMAN'S DIFFICULT LABOUR

Sixth edition, revised and enlarged. By CARLTON OLDFIELD, M.D. Lond., F.R.C.S. Eng., Honorary Obstetric Surgeon to the Leeds Infirmary, &c. London: Cassell and Co., Ltd. 1920. With 198 illustrations. Pp. 573. 16s.

IT is just ten years since the last edition of this book appeared, although it was reprinted in 1912. It has always been a popular book with both teachers and students, and we are very glad to see that the publishers have not allowed it to disappear. As the editor rightly says, it has long been a medical classic, and for nearly a generation a friend in need to many a general practitioner and many a resident obstetric officer. The book owes its reputation to the fact that it was written out of the large and ripe experience of its author, and its teaching has stood the test of time. For this reason the alterations that the new editor has had to make have been relatively few, and he has been able to preserve the salient features and distinctive qualities of the book. There are a number of new illustrations and some of the sections have been added to and partly rewritten, more especially those dealing with Cæsarean section and rupture of the uterus. The section on Cæsarean section has been amplified and the latest results given, as well as the more modern methods of operating. In the treatment of incomplete ruptures of the uterus the Carrel-Dakin method is recommended for the irrigation of the tear and of the uterus to prevent infection, and no doubt this should help to lessen the mortality of these cases. In the chapter on post-partum hæmorrhage there is a good description of the modern method of direct blood transfusion. Apparently the editor's results with gum solution have not been encouraging, but this does not correspond with the experience of most surgeons.

The book retains all its own characteristics, while Mr. Oldfield has added to its value by bringing it up to date, so that it is now, as it always has been, the best possible guide to the student and practitioner in the treatment of cases of difficult labour.

MANUAL OF OBSTETRICS

For Students and Practitioners. By O. ST. JOHN MOSES, M.D., C.M., D.Sc., F.R.C.S., F.R.S. Edin. London: J. and A. Churchill. 1920. With 136 illustrations. Pp. 528. 21s.

THE only excuse which legitimately could be put forward for adding another text-book to the many already existing excellent works on the subject of obstetrics would be that the book is as good as or better than any of its predecessors. We are afraid this can hardly be said for the work under review. It is obvious that the author is quite out of touch with the modern teaching of midwifery, and therefore his book cannot be recommended to any student as a safe guide. For example, we are told that the chorionic villi are covered with a basement membrane on whose surface is a close compact layer of fine-walled cells. The amnion is described as developed by a folding up of the somatopleure, and it is said to cover the developing umbilical cord. Not a word is said of the embedding of the early ovum in the decidua basalis, and the function of the decidua is imperfectly described. The diagram showing the height of the pregnant uterus at the various months of pregnancy is quite inaccurate. A carneous mole is said to be the result of polypoid deciduitis and to be covered with small polypi, which are involutions of the decidual tissue; the author has apparently never heard of a subchorionic hæmatoma. We are told that ovarian gestation has never yet been demonstrated, when already in 1906 Whitridge Williams had described 36 very probable cases, and since that date a number of certain cases have been published. In the account of the treatment of placenta prævia not a word is said of the use of Champetier de Ribes's bag for this condition, and under accidental hæmorrhage the student is recommended accouchement forcé, while plugging the vagina and Cæsarean hysterectomy are not even mentioned. In the section on instruments we are told that the écraseurs which are figured are useful for performing such operations as amputation of the cervix, and the removal of polypi or of the ovaries. One wonders where and when the author can have learnt these things.

The book is not at all up to date and cannot be recommended to the readers for whom it has been written.

THE NUTRITION OF THE FŒTUS

By J. MORRIS SLEMONS. New Haven: Yale University Press. London: Humphrey Milford. 1919. Pp. 50. 3s. 6d.

THE nutrition of the fœtus involves two factors—the peculiar activity of its own organs and the supply of food it receives. The second factor has been brought within the range of direct observations, and in this little brochure Dr. Slemons details the results attained. That the mother's weight increased during pregnancy has long been known, and at one time it was believed that fœtal growth occurred at the expense of the maternal tissues. This is, however, not so, and it has been shown that the food of the mother is sufficient not only for her own needs but also for those of the fœtus. Two theories have been held as to how substances pass through the placental partition which intervenes between the two circulations of the mother and the fœtus. The first, the vitalistic theory, assumes that the placenta digests the food of the fœtus, and the second, the mechanistic theory, supposes that the placenta plays merely a passive role and behaves as a semi-permeable membrane. One fact, at any rate, holds good, and that is that no insoluble substance can pass the placenta. Analysis of specimens of fœtal and maternal blood obtained simultaneously has enabled Dr. Slemons and his collaborators to make some notable additions to our knowledge of the action of the placenta. They have shown that there is a constant equality in the non-protein nitrogen content of the maternal and fœtal bloods, and that in the fœtal plasma there is always a slight excess of the amino-acids, pointing to the placenta being capable of absorbing them and preventing their departure from the fœtus. These observations also show that the nitrogenous fœtal waste products and glucose all pass through the placenta by diffusion. There is, however, a high fat content in the blood of the pregnant woman, a much lower one in the blood of the fœtus, and between the two circulations no interchange of fat or related substances.

This is a very interesting study and a notable addition to our knowledge of the physiology of the placenta.

PAINLESS CHILDBIRTH AND TWILIGHT SLEEP

Second edition. By CECIL WEBB JOHNSON, M.B., Ch.B., Captain, R.A.M.C. (T.F.), late Civil Surgeon and Officer Commanding Station Hospital, Dum Dum, &c. London: Butterworth and Co. Pp. 169.

DR. Webb Johnson has apparently had a considerable experience in administering twilight sleep in India, and this book is a résumé of most of what has been written on the subject and of his own conclusions. We may say at once that he is an enthusiastic advocate of this method of scopolamine-morphine narcosis. The subject is considered at length, and the many objections which have been urged against the method are discussed in detail. It is a pity that the author has not included a complete record of all the cases treated by him, omitting a great deal of the extraneous and unnecessary matter which he has introduced. The whole tone of the book is spoilt by some of the additions, and it suffers from the defect which most of the books on this subject suffer from—namely, that the reader is presented with the opinions of the author unsupported by any facts from which he can draw his own conclusions. It is only by comparing the carefully recorded results of large numbers of cases treated by this method that we shall be able to arrive at a just conclusion. Dr. Webb Johnson is strongly in favour of the complete Freiburg technique, and yet we find that in practice he appears to use the method of fixed dosage not infrequently. Here, again, in the absence of complete details we are uncertain which method has been most commonly employed. In using fixed doses the author, after an initial dose of morphine 1/6–¼ gr. and scopolamine 1/150 gr., or omnopon 2/3 gr. and scopolamine 1/150 gr., gives half-hourly injections of small doses of scopolamine, which he believes are more efficacious and much safer than larger doses at longer intervals. We are led to believe that the author has treated large numbers of cases, but we are not told the actual numbers nor the actual results in any form in which they can be compared with those published by other observers, and for this reason the scientific value of the book is small.

DR. CHAVASSE'S ADVICE TO A MOTHER.

Eighteenth authorised edition. By T. D. LISTER, M.D. London: J. and A. Churchill. Pp. 336. 2*s.* 6*d.*

WE cannot help regretting that this book has been reprinted. It has done useful work in its time, but it evidently has been too heavy a task to revise such a mass of detail when almost every word should have been rewritten. In these days a woman who employed a wet-nurse for her child, and forbade her "to visit her own baby," as recommended on page 33, would be execrated by every decent-minded citizen. If a wet-nurse is employed, she should nourish both her own and the foster-child, and not the latter at the expense of her own. This is by no means the only example of failure in revision, but we are most surprised in view of the recent prominence of the subject to see that two-hourly feeding—10 feeds in 24 hours—should still be upheld in the present edition.

It is easy to understand the anxiety to maintain something of the original form in a book which has been for many years useful in educating public opinion. The author has put a good quantity of new wine into this respectable old wine-skin, so we may, perhaps, hope that the skin will burst, and that the publishers will reward him with a new skin for the next season's vintage.

DIE MEHLFRÜCHTEKUR BEI DIABETES MELLITUS.

Von Professor Dr. W. FALTA, Vorstand der III. Medizinischen Abteilung und des chemischen Laboratoriums des Kaiserin Elisabethspitales in Wien. Berlin und Wien: Urban und Schwarzenberg. 1920. Pp. 388. 50 marks.

SINCE 1898, when Mossé advocated the treatment of diabetes by a diet consisting largely of potatoes, and more particularly since v. Noorden announced his "oat cure" in 1902, a variety of so-called carbohydrate cures for the disease have been described. Although some have had a limited vogue and satisfactory results from their use have been reported by a few observers in selected cases, no universally applicable treatment of this description has yet been found.

In the volume under review Dr. W. Falta of Vienna describes yet another variation of the same theme. Originally a disciple of v. Noorden he has abandoned the claim formerly made by the Vienna school that the success achieved with the oat cure depends upon some property peculiar to oatmeal, and ascribes it rather to the low protein content of the diet and the abundance of starch given. He now employs, therefore, a "mixed meal cure" in which wheatmeal, oatmeal, rice, barley, peas, beans, linseed, maize, millet, tapioca, and potato are combined, at first in the form of gruel and, later, as purées and soups. He contends that the control of acidosis in diabetes is, at least, as important as the limitation of the excretion of sugar, and, as the formation of the acetone bodies on which acidosis depends is related to the intake of protein, and can be prevented by an adequate supply of carbohydrate, it is necessary that the diet should be arranged with these objects in view at any cost. The particular kind of starch employed is not a matter of great importance; what is essential is that it should be given in large amounts and be varied so as to avoid the monotony attached to the original oatmeal cure. Although the allowance of protein is kept as low as possible a considerable amount of fat is permitted. As in the original oat cure the patient is prepared for his carbohydrate days by a series of vegetable and hunger days.

Despite the favourable cases quoted by Dr. Falta in a voluminous appendix, it is doubtful whether his "mixed meal cure" will prove a panacea for diabetes any more than the many other methods of treatment described for the disease. The fact that some cases respond to one form of treatment and some to another of an entirely different character suggests that diabetes is not a single pathological entity always amenable to the same therapeutic measures. Until means are devised for differentiating the various types accurately the most suitable form of treatment for any particular case can only be determined by a process of trial and error, checked by careful clinical and chemical observations, and in the course of this procedure the mixed meal cure should be as worthy of a place as others which are at present fashionable.

ACQUIRED SYPHILIS IN THE MALE.

An Atlas of the Primary and Cutaneous Lesions of Acquired Syphilis in the Male. By CHARLES F. WHITE, M.B., and W. H. BROWN, M.D. London: Bale's Medical Books. 1920. Pp. 32 and plates. 27*s.* 6*d.*

THIS work is the outcome of a photographic record of cases treated at a large venereal hospital during the war. The fact that the authors had at their command so much clinical material—as many as 19,000 cases of syphilis came under observation—renders the record a very complete one. The work is divided into six parts, the first three parts being devoted to Syphilitic Chancres and Soft Sores; the fourth part to Secondary Cutaneous Lesions; the fifth to Late or Tertiary Syphilides; and the sixth to Skin Diseases liable to be mistaken for Syphilis. The letterpress has been purposely kept within narrow limits. The descriptions are concise and clear, two qualities that do not always appertain to descriptions of cutaneous lesions in text-books of dermatology. Special attention is paid to syphilitic chancres and soft sores, since the early recognition of these lesions is a matter of vital importance. To render the illustrations still more instructive they have been arranged for use with a stereoscope, a fact which should certainly assist the reader in obtaining a clear mental picture of the lesions portrayed.

The whole aim of the work is to assist in the formation of a diagnosis. The Atlas is in no way a treatise on syphilis, and does not deal with such subjects as treatments or prognosis. It should prove of great value in assisting the student to obtain a clear impression of the types of lesions commonly seen in a venereal clinic. The Atlas will assist the effort that is being made to obtain earlier recognition of a disease that is fraught with such great consequences to the nation. The photographs from which the plates are prepared have been well selected. Altogether we congratulate the authors on the result of their labours.

THE PHILOSOPHY OF CONFLICT.

And other Essays in Wartime. By HAVELOCK ELLIS. London: Constable and Co., Ltd. 1919. Pp. 300. 6*s.* 6*d.*

THIS is a book to be taken on a holiday. It is a delightful and informing series of essays dealing with subjects literary, sociological, economic, medical, and biological—e.g., Martin Luther, Herbert Spencer, Baudelaire, Joseph Conrad, Cowley, the Origin of War, the Problems of Eugenics, the Unmarried Mother, the Political, Economic, and Psychological Position of Woman, the Drink Problem, Psycho-analysis in Relation to Sex. What more varied collection could the thoughtful physician or surgeon desire as a companion of his leisure, especially when the author writes from a point of view consistently progressive, yet always sane and moderate? The following extracts will but serve to whet the reader's appetite for a closer acquaintance.

War "probably began late in the history of mankind; it developed slowly out of animal hunting ...... above all, it owed its expansion to two great forces, the attractive force of booty and commercial gain in front, and the propulsive force of a confined population with a high birth-rate behind" (53). "A nation with a high birth-rate is not in a state of efficiency. That high birth-rate is the mark of immaturity, defective civilisation, and general inefficiency" (115) The two causes of war "are already decaying. The excessive birth rate is falling, and necessarily falls with every rise in culture. Excessive industrialism has likewise passed its climax, there is no new world left to fight for; and with the regularisation of industrial and commercial activities . . the economic cause of war falls away, and the energy thus released is free for sublimation into other and possibly more exalted forms of human activity" (55). Conflict of the kind that involves violence is not to be "regarded as the eternal and supreme type of conflicts in the world" (62) In regard to Freud, "We cannot understand him, unless we regard him as, above all, an artist" (206). "Truth or fiction, to the artist it is all one, even when the artist is a psycho-analyst, for he is only concerned with truth to his art" (205). "His (Freud's) theories have been proved to be often defective ... yet he enlarged the human horizon" (222). "He has shown the existence of a vast psychic field of which before we had but scanty intimations. The human soul will never again be to human eyes what it was before Freud explored it" (223).

Mr. Nevil Beauchamp, it may be remembered, "liked a bone in his mouth," when choosing his reading, to correct vagrancies and promote healthy activities Mr. Havelock Ellis in this book gives the reader plenty of bones to worry.

WHEELER'S HANDBOOK OF MEDICINE.

Sixth edition. By WILLIAM R JACK, B.Sc, M D. Glasg., Physician to the Glasgow Royal Infirmary Edinburgh: E. and S. Livingstone. 1920. Pp. 561. 12s.

THE principal change which has been made in this popular handbook since the last edition published in 1916 consists in an appendix of eight pages on the medical diseases of the war. This classification is no doubt convenient for the moment; it has helped in the successful attempt to keep the pagination of this edition identical with that of the last, but it is to be hoped that at a subsequent date trench fever and infective jaundice will find their way into the section on specific infectious diseases, while war neuroses will take their place as a somewhat specialised variety of the psycho neuroses of everyday life. While they are exalted to their present importance, and so much is written on treatment by suggestion, it is, perhaps, a pity that nothing is said of the method of "abreaction," which has proved so successful in the hands of Dr William Brown and others. A very few alterations are made in the body of the book, occasional additions being introduced while a new picture showing the position of the images in diplopia now takes the place of a diagram on p 500, which illustrated the action of ocular muscles Some of the minor criticisms offered in our review of the fifth edition have been met, and the value of a widely read manual has, we think, been enhanced

LA TENSION ARTERIELLE EN CLINIQUE.

Second edition. Par Dr. L GALLAVARDIN. Paris. Masson et Cie. 1920. Pp 720. 30 francs.

IN his preface the author claims that this is more like a new book than a new edition, embodying, as it does, all the work of the past decade The size of the volume may seem excessive at first sight, but it contains very little redundant matter. After all, as Dr. Gallavardin observes, it is scarcely an exaggeration to say that sphygmomanometry is to chronic disease what temperature records are to acute disease. The first part of the book is devoted to a study of technique. The author comes down on the side of the tactile method, with a Riva Rocci apparatus, for measurement of the systolic pressure. As for the diastolic figure, he favours either the vibratory or the auscultatory method. He considers that the auscultatory method gives a high systolic reading; presumably it is this that deters him from recommending its use for estimation of systolic as well as diastolic pressure, the plan which is largely adopted nowadays in this country.

After an admirable account of physiological variations in the blood pressure the book passes on to deal with the pathological variations. The section that will arouse most interest, doubtless, is that in which persistent hypertension is discussed. Its relation to renal disease is considered judicially and at length, but the author does not think it possible to state a theory which covers all the facts. The last section discusses blood pressure in various diseases and under the influence of various therapeutic methods.

This is a valuable book of reference, and we wish it could be translated into English. A word of praise must be given to the freedom with which the text has been illustrated by explanatory diagrams.

EFFICIENCY IDEALS.

By THISELTON MARK, D Lit, B Sc London: T. Werner Laurie, Ltd. Pp 127 2s 6d.

THIS little volume, bearing the subtitle "A Short Study of the Principles of 'Scientific Management,'" may be said to reach the average of the large number of books now appearing on the subject. Its author is obviously a keen enthusiast, but he lacks originality and judgment. Insufficient discrimination is made between "authorities," and the attitude of Labour towards scientific management is not adequately appreciated.

THE TRIAL OF HAWLEY HARVEY CRIPPEN.

Edited, with Notes and an Introduction, by FILSON YOUNG, Editor of "The Trial of the Seddons," &c London and Edinburgh William Hodge and Co, Ltd 1920. Pp 246 10s 6d

TEN years ago—apparently on Feb 1st, 1910—Crippen murdered his second wife, known to her friends as Cora Crippen or by a stage name as Belle Elmore He was convicted of murder and sentenced to death on Oct 22nd, after five days' trial at the Old Bailey, and in due course was hanged In the present volume, the latest of the well produced and interesting series of "Notable English Trials," are included a full report of Crippen's trial for murder and of the judgment of the court upon his appeal, a report of the trial of Le Neve, indicted as accessory after the fact and acquitted, and the contents of sundry documents more or less connected with the case. The editor, Mr. Filson Young, in a picturesquely written and interesting, if somewhat gossipy, introduction, refers to the murder as a "*crime passionel*" (sic). No doubt the murder of a wife in order to live with another woman may be so described, and this element, the flight across the Atlantic with a girl dressed in boy's clothes, and the sensational demonstration of the usefulness of the new wireless telegraphy in bringing about the capture of a criminal, excited widespread interest. With all this, however, the principal, if not the only, feature of the case rendering it worthy of inclusion in a series of important criminal trials lies in its medical interest. Scientific evidence hanged Crippen when once the friends of the dead woman had called the attention of the police to her mysteriously sudden and complete disappearance and to the clumsy fictions with which he was seeking to explain it. Certainly Crippen in the disposal of his victim's body had been wonderfully ingenious up to a certain point. He had dismembered it and got rid of head, limbs, bones, and sexual organs so that they were never found, but he had buried under the floor of the cellar at his house in Hilldrop crescent the viscera of the chest and abdomen, in which hyoscine was stated to be traceable, and among fragments of epidermis one was indelibly marked by the scar of an abdominal operation. The gruesome remains submitted to the jury had been in the ground for nearly six months The identification of the scar as a scar, and not a mark caused by the folding of the piece of skin, was in the able hands of Mr. A. J. Pepper, Dr. B. H. Spilsbury, and Dr. T. Marshall. Dr W. H. Willcox explained how he had examined portions of the stomach, intestines, liver, and kidneys, and satisfied himself that an alkaloid present was hyoscine. Dr. A P. Luff corroborated Dr Willcox while medical evidence called by the defence, questi ing the identification of the scar and of the hyoscine, failed to impress the minds of the jury with any reasonable doubt.

Crippen had described himself in the witness-box as a doctor of medicine of the Cleveland Homœopathic Hospital, U.S.A., and his principal business in England seems to have been to sell homœopathic medicines and "remedies," purveyed by a firm known as Munyons. It was in the course of this kind of trade that he claimed, uncorroborated in any particular, to have dispensed in a few months and got rid of the greater part of the five grains of hyoscine, the proved purchase of which he did not deny. Some he claimed to have left behind at his office, and in this, again, he was uncorroborated, as he was in his assertion that homœopathic practitioners recommend the administration of the drug in certain diseases. In a letter to Le Neve, written when under sentence of death, and quoted by Mr. Young from the *Daily Mail*, the doomed man included long arguments as to the identification of the piece of skin with a scar on it. It is characteristic of the psychology of the criminal, confronted with proof of his guilt, to believe that failure of the prosecution to establish one point in its case would involve the destruction of that case in its entirety, and further, would, to quote Crippen's words in his letter, "put him right before the world." The scar was of undoubted importance in proving the identity of the scanty remains found, but it is hardly conceivable that even without the piece of skin in question the case for the Crown would have been withdrawn from the jury. The presence of hyoscine did not identify the remains as those of Cora Crippen, but with them were dyed hairs darker at the roots where the natural colour showed, such as her hair had been observed to be, and portions of a woman's underclothing corresponding with what she was proved to have worn. The case for the Crown was convincing enough, and if anything was wanted to strengthen it, the explanations of his conduct, or the lack of explanation, afforded by the accused in the witness-box, supplied all that was needed.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

VITMAR (VITAMINE FOOD).

(CALLARD AND CO., 74, REGENT-STREET, LONDON, W. 1.)

THERE is no reason why palatable materials rich in vitamines should not be prepared now we know the sources in which the accessory factors occur in abundance and the methods of retaining their activity. Vitmar is stated to be manufactured by a difficult and delicate process from wheat, bone marrow, eggs, fruit, and sugar. Chemical analysis so far is not able to disclose the actual presence of vitamines, but fat to the extent of 11·64 per cent. was extracted, which showed the presence of phosphorus, a characteristic of both egg fat and bone marrow. The mineral matter, though low, proved to be rich in phosphate. The fats are well emulsified, and there is no reluctance shown by children to taking the preparation. On the contrary, they like it, and that is an important point in regard to a product claiming to contain all three accessory factors—fat-soluble A (growth promoting), water-soluble B (anti-neuritic), and water-soluble C (anti-scorbutic). The presence of fruit juice was confirmed by a positive response to the well-known tests for the organic acids normally contained in it. The moisture amounted to 21·35 per cent. We have received a report by a well-known bio-chemist, in which is set out the vitamine value of Vitmar in experiments made on rats. It would seem from this report that this preparation represents an earnest attempt to consolidate accessory food factors.

ANTI-VERMIN PASTE.

(THE SANITAS COMPANY, LTD., LOCKSLEY-STREET, LIMEHOUSE, LONDON, E.)

The principle on which this anti-vermin paste is designed is, we think, sound, judging from the evidence of practical experience gained in regard to it, and generally from a consideration of its composition. It contains a well-known and proved insecticide, which, however, is present in a solvent. Mere contact with the warmth of the body suffices to volatilise the insecticide, which then does effective work. It is pointed out that "stoving" a man's clothes and washing and shaving him is not a real preventive measure, since when he returns to an infected place he is soon open to further attacks. The plan with this ointment is to smear as much of it as will go on a threepenny-piece along the top band or collar of the shirt, the seam under the arm, the crutch seam of the trousers and the inner seam at both knees, and, if the vermin are on the head, round the lining of the cap or hat. The volatilisation by the warmth of the body of a really effective insecticide from a paste appears to be a business proposition. We have assured ourselves of the composition of the paste, and have extracted and identified the active volatile constituent present. The originator of the paste has had considerable experience in sanitary administration through the war, and there is clearly a field still left open for conquering disease-carrying vermin. The Sanitas Company seem to be putting on the market here a much required preparation.

AMBROSIA MILK AND COCOA POWDER.

(AMBROSIA, LTD., BRIGHTON CHAMBERS, DENMAN-STREET, LONDON BRIDGE, S.E. 1.)

The analysis of this preparation gave the following results:—

Moisture ...	5·10 per cent.	Reducing sugar ...	11·80 per cent.
Mineral matter	3·25 ,,	Protein ...	13·23 ,,
Fat	16·56 ,,		

The mixed dried milk and cocoa makes a pleasant nutritive cup, and the proportion of fat and protein is notable. More than half of the powder is soluble in cold water, which is due largely to the presence of sugar as a sweetening agent.

CHLOROSAN.

(SWISS SERUM AND VACCINE INSTITUTE, BERNE.)

The suggestion is novel that the very interesting substance chlorophyll is likely to help in cases of anæmia and chlorosis. Chlorophyll, of course, is related to hæmoglobin, the former being the medium by which carbon dioxide under the influence of light is absorbed by plants with the ultimate liberation of oxygen, and the latter the medium by which oxygen is absorbed by animals with ultimate liberation of carbon dioxide. In modern terms they both serve as catalysts. Whether chlorophyll releases oxygen in the human system may be open to doubt, and its fate in gastric metabolism would be interesting to determine. We are told that the preparation submitted to us is based on chlorophyll, as the result of experiments and researches by Professor E. Bürgi and his collaborators at the Pharmacological Institute of the University of Berne. Our examination confirmed the presence in the capsules of chlorophyll. The usual spectrum absorption was shown by a solution of the contents, and the mineral matter contained magnesium (particularly) and some iron. It is interesting to note that the hæmoglobin, as we may call it, of plant life contains magnesium as its chief metallic element, while the hæmoglobin of animal life has as its metallic foundation iron.

SEDOBROL ROCHE.

(THE HOFFMANN-LA ROCHE CHEMICAL WORKS, LTD., BERNE, AND 7 AND 8, IDOL-LANE, LONDON, E.C. 3.)

We have referred to this preparation before, but a specimen of a new packing has reached us which gives greater convenience when attempting to control the administration of bromides to the patient. Sedobrol is a combination of bromide of sodium and vegetable proteins. It produces, in fact, a bromide soup made from tablets dissolved in hot water, in amounts controlled by the physician. The saline taste of the bromide provides a "seasoning," which otherwise common salt would be called upon to do, while, of course, the bromide has well-known sedative effects. This administration may have its advantages, but should be conducted strictly at the discretion of the medical adviser.

THE LANCET.

LONDON: SATURDAY, APRIL 10, 1920.

The Medical Research Council.

THE *draft of a Charter for creating the members* of the Medical Research Committee a body corporate, under the style and title of "The Medical Research Council," has received the King's approval on the advice of the Privy Council, and a warrant has been prepared for His Majesty's signature in conformity with the draft. Under the warrant, from the first day of this month the Medical Research Committee, as at present constituted, ceases to exist, while the duties heretofore discharged by that Committee will be discharged, with enlarged scope, altered position, and increased discretion, by the new body. The representations made to His Majesty by the Lord President, the Minister of Health, the Secretary for Scotland, and the Chief Secretary for Ireland, acting as a Committee of the Privy Council, having been accepted, it is now directed that the members of the late Medical Research Committee—namely, Lord GOSCHEN, Mr. WILLIAM GRAHAM, M.P., the Hon. EDWARD F. L. WOOD, M.P., Mr. C. J. BOND, Professor WILLIAM BULLOCH, Dr. THOMAS RENTON ELLIOTT, Dr. HENRY HEAD, Professor GOWLAND HOPKINS, Sir WILLIAM LEISHMAN, and Professor D. NOEL PATON—under the name of the Medical Research Council, shall succeed to the old and the new responsibilities.

The Medical Research Council will have a perpetual succession and a common seal with full power, by and in such name:—to sue and be sued; to enter into contracts or agreements under the direction of the Committee of the Privy Council; to hold and dispose of money and personal property including Parliamentary grants; to accept trusts; and generally to further all the objects for which the Council has been established, and the Committee of the Privy Council appointed. The only limit to the activities of the new body which is mentioned, save that all its acts should be conducive or incidental to the purposes of its establishment, is that purchase or lease of land within the United Kingdom shall not exceed in the whole an annual value of £50,000, a customary enactment when there is question of lands held by a corporation in inalienable tenure. A provision for maintaining the Medical Research Council in touch with the growth of science and with the development of national necessities enjoins that three members of the Council, to be selected as the Committee of the Privy Council may determine, shall retire at intervals of two years; but any member so retiring is eligible for reappointment, thus securing a continuity of special work. Appointments to vacancies, whether casual or otherwise, will be made by the Committee of the Privy Council, after consultation with the President (for the time being) of the Royal Society, and with the members of the Medical Research Council; and, as is usual, those appointed to fill casual vacancies will only hold office for the remainder of the appointed period of those whom they replace. Two members of the Medical Research Council must at all times be members of the House of Lords and the House of Commons respectively, which ensures the legislature being informed intimately, should questions arise requiring discussion in the public interest. The Council will appoint its own chairman, treasurer, and secretary, with the approval of the Committee of the Privy Council, as well as any other officers and servants for administrative purposes. Lastly, there are provisions by which, upon the vote of an absolute majority of the whole of the Council, alterations, amendments, and additions may be made to the Charter.

The Charter will appear to all scientific men to mark a valuable and significant advance in the position of science in this country. Under it the Medical Research Council may be described as a permanent standing subcommittee of the Privy Council, a body whose acting members are principally formed from the Cabinet and whose President is always a prominent member of the Cabinet. The Medical Research Council will thus have direct access to Ministers, and will not have to submit proposals through any intermediary. It will, moreover, work under the immediate dispensation of a Committee of the Privy Council, consisting of the three Ministers of Health of the respective divisions of the United Kingdom, whereby all its plans for the scientific development of medicine and for the direction of research into the channels most fruitful for the health of the people will come at the earliest stage before those who have supreme charge of the health departments of the kingdom. Endless opportunities for misunderstanding and for delay will thus be eliminated. The circumstances in which the help and intervention of the President of the Royal Society may be sought are exactly suitable. From the time of its foundation, or at any rate of its first charter of incorporation, the Royal Society has been constantly relied upon by Government for scientific advice. Looking at its medical work, it has assisted especially to clear up difficulties in connexion with colour-blindness, malaria, Mediterranean fever, and many forms of tropical disease, while it has the duty already of administering annual grants on behalf of Government for the promotion of sci research. The direct association of the Society with the work of the Medical F Council is appropriate, and cannot fail to valuable.

Delayed Salvarsan Poisoning.

THE series of cases of delayed salvarsan poisoning reported by Dr. G. S. STRATHY, the late Captain C. H. V. SMITH, and Dr. B. HANNAH has at first sight a somewhat formidable appearance (see p. 802). Fifty-eight cases from one hospital, of which seven out of the eight fatal cases occurred within about five months, would represent a serious state of affairs if it were typical of the experience of military venereal hospitals, or of the hospital in question for more than a limited period. It is clear, however, that this series provides another example of the local and temporal concentration, the occurrence in groups or "outbreaks," characteristic of the incidence of the cases of this form of delayed poisoning which have been reported during the war. As in *the case of* trinitrotoluene poisoning, which presents many points of rather suggestive similarity, this occurrence of cases in groups, resembling small epidemic outbreaks, has naturally raised the question of an intercurrent infection. The possibility that specially toxic batches of the arsenical preparations were responsible has also naturally been suggested; just as the suspicion arose that certain kinds of trinitrotoluene were peculiarly dangerous. It will be seen that the authors of this paper, with apparently good reason, discount all such possibilities, and attribute the *unfortunate experience* to an unwise persistence in intensive treatment without due regard to or search for the signs of susceptibility in certain patients.

Doubtless all these possibilities will be fully discussed in the further report which has been promised by the special Salvarsan Committee, appointed by the Medical Research Committee in 1918. Meanwhile, it is *important* to bear in mind that the outbreaks of such poisoning, taken altogether, represent a minute proportion of the total number of cases receiving this treatment in military hospitals *during the* war. Considering the nature of the problem with which the military uthorities were faced—the large number of cases e treated, the relative novelty of the treatment n war broke out, and the urgency for such nsive administration as would return a man to ty in the minimum time—the number of cases f serious trouble seems to have been remarkably mall. At the same time it is important that full se should be made of the experience afforded by uch cases as have occurred, with a view to the omplete elimination of danger from a treatment which has established itself as, beyond comparison, the most effective at present available for syphilis. It is therefore of special value that the authors of the paper are able to indicate the precautions which they found effective in detecting and forestalling danger, and the treatment by which, after the first eight cases had proved fatal, they were able to restore the succeeding 50 affected patients to health. Their method of detecting the first signs of liver atrophy by means of the X rays appears to be novel. It will be seen that they regard the condition with which they deal as essentially a delayed *arsenical poisoning*, and quote an interesting case in which a somewhat similar condition was produced by Fowler's solution in a non-syphilitic patient. The interest of the latter case, however, must be largely attributed to its rarity. It is very probable that others have laid too much stress on the organic part of the salvarsan molecule in considering the evidence of its remote toxic action; but to speak of the effect simply as "delayed arsenical poisoning" is surely to swing rather too far in the other direction. The condition has, indeed, some features in common with that which may be produced by inorganic arsenic; but, as indicated above, it has also points of similarity to those which have been found to follow persistent absorption of certain organic compounds containing no arsenic.

◆

The Value of Debate.

WE have received recently complaints from th who have been invited to address meetings medical societies, and societies of allied bear that the audiences who assembled have been scanty that the main object for the delivery of address was frustrated from the beginning, in t no sort of representative debate could poss ensue. These complaints have reached us regard to meetings of *different sections* the Royal Society of Medicine, as well in regard to other societies of less scien standing, but as some of these latter bodies ar wider scope it might have been expected that t assemblages would appeal to a greater numb persons. This seems not to be the case, *gatherings at the Royal Institute of Public He* for example, being as often as not very s Such a situation is every whit as vexatious for officials in charge of the meetings as for lecturers, and the position should be conside without any suggestion that the fault can attributed more to one side than to the oth but solely with a view to the remedy of wha now a waste of time and of opportunity.

The main object which a lecturer should have addressing these meetings is the stimulation o debate, for if publicity only is desired this will *obtainable in* an indefinitely larger measure b issue in a journal. Experience has shown ove and over again exactly what it might have bee expected to show—namely, that a keen debate of surgical, medical, or pathological subject, which i topical or which presents generally *felt* obscuritie in diagnosis or treatment, is followed by some concrete piece of progress. When a subject needs debate for the reasons just indicated, and when those present, speaking *from personal* experience, shape the controversy towards the real points of difficulty, practical therapeutics take a step forward. The enormous difference between the written and the spoken word then appears, and men who in attempting to settle their differences by correspondence would remain to the end at variance, find themselves, probably to their surprise, in accord over many essentials, and ready to allow that what is left over for quarrel is largely not worth quarrelling about. In a debate a man can re-state his position, and in some new form the details which previously had puzzled his adversaries may become the arguments for the making of friends. And this charming situation is reached in three minutes, and reached without reservation, while three months spent in correspondence would have produced no real agreement. There is no necessity to labour this point. Everybody knows that a well-guided discussion is the way either to arrive at the truth or to construct the methods by which the truth may be arrived at; and accordingly everybody will regret any widespread feeling that it is not worth while to debate a medical subject at a learned society because the audience, neither in quality nor quantity, is likely to provide a useful discussion. Yet this is exactly what may happen if the average of unsuccessful gatherings grows larger.

The Royal Society of Medicine, said Sir Arbuthnot Lane in a recent speech, is the best medical society in the world; and we do not think it is British swagger to claim that no other learned body is so representative of the medical science of its country, or provides in so orderly a manner that every section of that science should receive proper recognition and proper opportunities, both for threshing out difficulties in its specialty and for calling in other sections to assist in its discussions. Because the Royal Society of Medicine is so strong and so well managed, we have the less hesitation in suggesting that the authorities of the Society should look closely into this subject of ill-attended debates, and should arrange that they should occur as infrequently as possible. Perhaps there should be a more rigorous scrutiny of subjects which are proposed for papers; and perhaps there should be a more efficient manner of securing an audience. We feel sure that if it is admitted that there is at present something wrong, we shall not have long to wait for steps to right it.

◆

Military Training as a Panacea.

The report upon the physical examination of men of military age by National Service medical boards, which we have been studying from week to week, gives the material for a rough physical census of Great Britain. There has never been a real survey of man-power in the United States of America. Even the recording of births has not yet become a practice universal throughout the federation, and the recent war did not come so closely home there as to necessitate the enlistment of every moderately healthy male person. But much knowledge came to hand during the systematic examination of the draft in 1917–18, and Dr. Merritte Ireland, now Surgeon-General of the United States Army, uses this knowledge to form an estimate of the physical and hygienic benefits of military training, which appeared in the *Journal of the American Medical Association* for Feb. 21st, the last issue to reach this country. Dr. Ireland tells us that among a total of nearly five million men examined for the Army, Navy, and Marines, 47 per cent. were found to have physical defects and 21 per cent. disabilities of sufficient gravity to lead to rejection. These have not yet been numerically classified as a whole, but a large sample of the early draft showed the percentage incidence of defects to be somewhat as follows: Flat-foot, 11; venereal diseases, 8·6; hernia, pronounced or latent, 4; defective vision and defective growth, each 3½; organic heart disease, 3; tuberculosis, 2·5. Dr. Ireland would have us know that the high venereal rate was due to infection prior to enlistment, so that the whole of the disabilities tabled may be regarded as the natural result of present-day American civil life.

Regarding the 53 per cent. who were accepted as fully meeting the physical standard laid down for enlistment, even with them all was not well. On the arrival of the recruit at camp the inspectors reported over and over again on the stream of awkward, narrow-chested men with flabby muscles, and often with a stoop; these formed a marked contrast to the bronzed, erect, broad-chested soldiers of fine muscular development and alert, self-confident air, who presented themselves for examination before demobilisation, and who were the same persons. Military training added 15 to 20 pounds of weight to the average recruit, the gain being regarded by Dr. Ireland as due almost entirely to muscular tissue. He speaks of the low record for venereal disease of the American army in France, and of the effect of the discipline of military life, as a whole, in producing better material for citizenship. The article ends with an eloquent plea for universal military training in order to give an opportunity of a physical survey each year of the youth of the land, with a view to the detection and remedy of physical disability. No other class of men, to quote Dr. Ireland's words, have the vision, as medical men have, to see the good that would result from such universal training.

But military training is not the only panacea which has been suggested, even in America, to attain this very desirable end. For one thing it often comes too late; at 19 years of age much of the harm arising from faulty habits of life is already done and cannot be remedied. Fresh air, exercise, cleanliness, rest, regular meals, and careful supervision are the remedial factors in the training of the recruit. They are also the essential conditions for the upbringing of the child, and, to quote Sir George Newman's recent Memorandum to the Minister of Health upon the prac of preventive medicine, they are as certain in their beneficial physical effect as they are conducive to the creation of a mental atmosphere favourable to the opening mind. Applied early in life, these things become part of a child's instinctive equipment. Understood thus they form a hygienic education which turns out hygienic graduates who do not require to cram for a recruiting examination, or at most need a repetition course. In this country the boy-scout movement has already done wonders in the physical and mental education of the juvenile population. The syllabus of physical training issued in 1919 by the Board of Education may do as much when it is fully applied. The ordinary conditions of life and upbringing should fit the adolescent for the struggle of life as well as, if need be, for the field of battle.

Annotations.

"Ne quid nimis."

THE MEETING OF THE BRITISH MEDICAL ASSOCIATION AT CAMBRIDGE.

THE annual general meeting of the British Medical Association will be opened at Cambridge by the President, Sir Clifford Allbutt, Regius Professor of Physic in the University, on Tuesday evening, June 29th. The Representative Meeting will begin on the previous Friday morning.

The Section of Neurology and Psychiatry has completed its preliminary arrangements. On the morning of Wednesday, June 30th, a discussion on the Early Signs of Nervous Disease and their Interpretation will be opened by the President of the Section, Dr. Henry Head. A discussion on Dementia Præcox and its Relation to other Conditions will be opened by Dr. Bernard Hart on Thursday morning, and on the following morning Dr. T. A. Ross will introduce a discussion on Psychotherapy, to which numerous speakers have expressed their desire to contribute. A series of demonstrations in the Medical Buildings will be given on one afternoon, and on another microscopical and other demonstrations will be given in the Physiological and Psychological Laboratories.

The proceedings of the Section of Pathology and Bacteriology are also arranged. The Section will devote the first morning (Wednesday, June 30th) to morbid anatomy, when a discussion on Atrophy of the Liver will be introduced by Professor Stuart McDonald, of Newcastle. The morning of July 1st will be given to experimental pathology, when Dr. J. A. Murray, Director of the Imperial Cancer Research Fund, will open a discussion on the Present Position of Cancer Research. The third morning (July 2nd) will be given to bacteriology, and Dr. J. A. Arkwright, of the Lister Institute of Preventive Medicine, will open a discussion on the Bacteriology of Cerebro-spinal Fever. A collection of specimens to illustrate the three subjects will be shown. The afternoon of each of the three days will be devoted to a meeting of the Pathological Society of Great Britain and Ireland; details of the papers to be read and the demonstrations to be given will be published later.

RESIGNATION OF THE MINISTER OF HEALTH FOR IRELAND.

OUR Dublin Correspondent writes: "The resignation by Mr. I. Macpherson of the Chief Secretaryship for Ireland has terminated the tenure of the first Minister of Health for Ireland. Beyond the fact that he was Minister of Health, and thereby established a precedent, it can hardly be claimed that the late Chief Secretary made any lasting mark upon health matters in Ireland. His housing schemes appear to have been stillborn. It is true that he sent encouraging messages to the Irish Public Health Council, suggesting that that body should devote its attention to devising a radical scheme of reform; but, like a more famous pro-Consul, he has not stayed for an answer. When the answer is ready it will, no doubt, depend on the will of his successor whether the scheme will bear fruit or not."

MENINGOCOCCI IN THE PETECHIÆ OF CEREBRO-SPINAL FEVER.

IN the *Journal of the Royal Army Medical Corps* Lieutenant-Colonel Robert Muir has reported two cases in which the interesting observation of the presence of meningococci in the petechiæ of cerebro-spinal fever was made. He refers to the fact that war experience showed that meningococcus septicæmia is much more frequent than was supposed; numerous cases without meningitis have been recorded and meningococci have been demonstrated in blood films made during life. The finding of organisms in the petechiæ is, therefore, not surprising. The meningococci may occur in large masses, leading to blocking of the minute vessels and thus to hæmorrhage. But it is not suggested that all petechiæ are so produced; they may also be the result of toxic action, as is generally supposed.

An American private, aged 26 years, was admitted to hospital from a troopship on Sept. 29th, 1918, as convalescent from influenza. Progress was satisfactory till Oct. 4th, when at 8 A.M. he had an attack of grea restlessness. The temperature was 103·8° F., and ther was an abundant petechial eruption on the trunk an limbs. He died at 10.45 from rapid heart failure. Th necropsy showed no trace of meningitis, and meningococci could not be found, by culture or microscopi examination, in the brain or cord. In both lungs wer a few patches of recent pneumonic consolidation, partl hæmorrhagic. The spleen was considerably swollen and soft. Films made from the petechiæ showed Gram-negative diplococci in considerable number, mostly lying free, but some within leucocytes. Cultures from the blood post mortem gave an impure growth in which Gram-negative diplococci were present. They were also found in films made from the pneumonic patches.

In the second case another American private, aged 23 years, was admitted convalescent after influenza from a troopship on Sept. 29th, 1918. He suffered from cough with purulent sputum and occasional epistaxis On Oct. 5th, at 2 A.M., he had an attack of vomiting At 7.30 a purpuric eruption was noted on the face and trunk. He rapidly sank and died at 9.55. The findings at the necropsy were closely similar to those of the previous case. Films made from a petechia showed numerous Gram-negative diplococci both inside and outside leucocytes. Sections of the petechia showed the organisms in large numbers within the minute blood-vessels. The meningococcus was cultivated both from a petechia and from blood taken from a vein in the arm.

Similar observations were made by Netter and Salamier in 1916. They described two cases of cerebro-spinal fever in children, one without meningitis, in which Gram-negative diplococci, presumably meningococci, were found in films made from the purpuric spots. Several writers have noted inflammatory reaction around the vessels involved. In connexion with the presence of meningococci in the petechiæ of cerebro-spinal fever, it is of interest to recall the fact that typhoid bacilli have been found in the rose spots of typhoid fever.

BREAD ABROAD.

IN view of the intention of our Government to reduce the bread subsidy in the coming financial year by 45 millions, which involves a rise in the price of bread to the consumer of 2½*d.* per loaf on April 12th, the following paragraphs taken from the *Economic Review* (March 31st) dealing with the bread position in Austria, France, and Germany are of interest.

AUSTRIA.—*Increased Price of Bread.*

The Lower Austrian Government has increased the price of bread by Hr. 28 per loaf as from March 7th. Bread will now cost Kr. 5.60 per loaf, as against Kr. 2.40 at the beginning of the year. (*Neue Freie Pr.*, March 4th.)

FRANCE.—*New Bread Prices.*

At a debate in the French Chamber on the price and supply of bread, it was stated that for the last three years the State had been losing Fr. 4 milliards a year on bread. The actual price of bread should be Fr. 1.50; the Government was taking very moderate action. The number of persons to whom cheaper bread would be granted had been greatly increased by a new decree; one-quarter of the consumers would pay a reduced price. The wheat deficit was so great that the import would have to amount to half the consumption. A fleet of 2 million tons would be required to transport it. The decree increasing the price of bread as from March 15th was passed by 475 votes against 68. (*Débats*, March 14th.)

As from March 15th the retail price of plain and fancy bread in Paris is as follows:—

80 g., Cent. 10; 180 g., Cent. 20; 270 g., Cent. 30; 370 g., Cent. 40; 450 g., Cent. 50; 500 g., Cent. 55; 550 g., Cent. 60; 650 g., Cent. 70; 750 g., Cent. 80; 850 g., Cent. 90; 950 g., Fr. 1; 1000 g., Fr. 1.05.

Fancy loaves weighing at least 700 g. and not more than 80 cm. long, Fr. 1.05 per loaf; rolls weighing from 70 to 80 g., and not more than 25 cm. long, Cent. 20. Delivery, Cent. 5 per loaf.

Flour sold to customers in the ratio of 50 g. per person per week, Fr.1.50 per kg. (*Débats*, March 13th.)

GERMANY.—*Increase in the Price of Bread.*

Owing to the large increase in the prices of coal and yeast the Greater Berlin Food Committee has raised the price of the 1900-g. loaf from March 15th to Mk.2.65, and of the 1600-g. invalid's loaf to Mk.2.55. (*Deut. Allg. Ztg.*, March 9th.)

Dr. Hans Guradze, of Berlin, gives in *Jahrbücher für N. u. St.* (February) tabulated statistics of the prices charged for wheaten and rye bread in Berlin during 1919.

It will be seen from these figures that the most serious advance in the price of bread is in Austria, while the situation in France is not very agreeable when it is officially stated that the wheat deficit is so great that the import would have to amount to half the consumption and "a fleet of 2 million tons would be required to transport it." This country may be grateful to its food administrators who have maintained a bread-supply throughout the war and who do not now propose, in spite of reducing an enormous subsidy, an alarming advance in prices in the future. According to the journal quoted above, frauds are being perpetrated on the public in Madrid by means of short weight of bread. The kilogramme loaf, we are told, rarely weighs 950 g. and not often more than 860 g. As the daily consumption realises 200,000 kg., the shortage amounts to 20,000 kg., representing a loss to the public of about 13,200 pesetas per diem value in bread. This statement is remarkable, since short weight is much more easily checked than are sins of adulteration.

LOCAL INJECTIONS FOR GOITRE.

Dr. J. E. Sheehan, of New York, published in 1917[1] a report of 17 cases of goitre treated by injections into the gland of carbolic acid, tincture of iodine, and glycerine in equal parts. In the *Journal of the American Medical Association* for Jan. 10th, 1920, Dr. J. E. Sheehan and Dr. W. H. Newcomb, both of whom are instructors in the nose and throat department of the New York Post-Graduate Hospital and Medical School under Professor Beaman Douglas, report a further series of 80 cases injected in a similar way. They have been greatly interested in this form of treating diseased thyroid glands, as a means of relieving or curing the pathological condition, during the past five years. Through the courtesy of Professor Douglas they have been able to observe all cases of goitre coming into the nose and throat department. Eighty cases of all forms of goitre have been treated during the past two years with the combination described above, five drops being injected into the most prominent part of the gland, the process being repeated every five days or so. They state that the object of the treatment is to produce an inflammation which eventually causes a fibrosis in the gland and an obliteration of that part of the gland injected. Such injections are said to be especially favourable in the ordinary parenchymatous goitres of young women. Of 55 patients of this type so treated 76·4 per cent. were cured. In 14 toxic cases relief was afforded in 80 per cent. The treatment was useless in the cystic or colloid form. In fact, in these cases the authors state that if treatment be persisted in it may do harm, causing a sudden enlargement of the gland which may seriously interfere with respiration. In suitable cases—that is, in all but the cystic or colloid form of goitre—it quiets the heart's action, improves the appetite, has a favourable effect on metabolism, stays emaciation, and reduces the mental irritability. It is the custom of Dr. Sheehan and Dr. Newcomb to inject with this mixture all goitre cases which are to be operated on, as the relief of the toxic symptoms aids appreciably in the success of the operation. The procedure is stated to be a safe one if the technique is not at fault.

HOME HELPS.

AFTER skilled help at the confinement—and not very far after, moreover—comes next in importance help in the home to relieve the mother of the anxieties of household management during the first few weeks of the new life. It is perhaps impossible for anyone except the mother herself to realise the intolerable burden which cleaning, cooking, sending the children well-groomed to school, and the hundred tasks of the house, mean to a woman already fully occupied with the manifold minor—but none the less straining—anxieties and accidents inevitable in the nursing of a young infant. There can be no doubt that, second to a midwife or doctor in her time of trial, the greatest gift to the working mother would be home help during the time of recovery. Such help is, of course, now a recognised public health measure, thanks to the initiative and foresight shown by the Local Government Board in its well-known Memorandum of August, 1918, in which the various aspects of maternity and child welfare were epitomised. It would be interesting to know how many local authorities have so far made use of their opportunities. It is not, perhaps, fair to judge by the annual reports of medical officers of health for 1918, which are all that are so far open to inspection. These came too closely on the heels of the Memorandum in question for much action to be possible. At any rate, it is apparent that action did not in fact follow, for, in a perusal of 26 consecutive annual reports, taken at random, of counties and of large towns and cities, not a single instance was found in which the subject was discussed; and in only one was the matter mentioned at all, and then rather as a pious aspiration than as a practical problem. There is this to be said in extenuation of the omission; it is not easy to propound a working scheme for the purpose. Is the home help, in the first place, to be a whole-time or a part-time servant of the authority? From every point of view, except perhaps that of cost, the whole-time help is preferable. How is she to be obtained? The type needed is to be found among the cronies of the mothers who attend welfare centres, and probably the best course is to use the welfare centre as an intelligence department for the purpose. Through it the chances of finding the suitable type are reasonably great. The training in simple cooking, household cleaning, washing, and marketing—in which the help-elect is probably already no mean performer—can best be done through the welfare centre. It is clearly best that she should pivot on the welfare centre at which many of her clients will attend rather than be attached to some more detached section of the public health department. The financial question may be a difficulty; it is unlikely that the whole of her salary can be met by the contributions of patients, even with the institution of a form of insurance in the case of all expectant mothers at the centre. But the financial is not the greatest difficulty. The kernel of the problem is the mother herself, who in many cases will, after a day or two of intense relief, resent the invasion of her territory and the exploration of her pet cubby-holes by a strange woman. A successful scheme must take into account the psychology of home-life.

[1] New York Medical Record, Oct. 6th, 1917.

SYPHILIS OF THE BLADDER.

ACCORDING to Dr. Loyd Thomson,[1] of Hot Springs, Arkansas, the literature on syphilis of the bladder is comparatively meagre. Of 84 cases on record only 58 are accepted by him as authentic. He thinks it probable, however, that this number does not represent the true incidence of the condition, and that it would be more frequently found if more attention were paid to it. He suggests that if the vesical mucosa of every case of syphilis in the eruptive stage were examined with the cystoscope involvement of this viscus would be found in a large percentage of cases. In the early stage of syphilis there is more or less congestion of the mucous membrane of the bladder resembling the diffuse eruption sometimes seen in the mouth and pharynx, or there may be a distinct papular eruption with or without erosion or ulceration. In the later stages the most frequent type of lesion is the ulcerating gumma, which may be either single or multiple. The usual site of the lesions in the early or late stage is round one of the ureteral orifices, but other portions of the bladder wall may be attacked. In the early stage the most frequent symptom is frequent and painful micturition, hæmaturia being the predominant manifestation of the late stage, and often the only one. There is, however, nothing characteristic in the symptoms or cystoscopic picture of syphilis of the bladder, and the diagnosis must rest upon the history, the presence or absence of the manifestations of syphilis, including the Wassermann reaction, and upon the result of specific therapy. The prognosis, on the whole, is good. Only 4 of the 58 cases died, death being due to the malignancy of the syphilitic infection. In all the other cases complete recovery followed the use of specific remedies.

CRUSADE AGAINST ANKYLOSTOMIASIS IN BENGAL.

THE prevalence of hookworm disease amongst the native population of Bengal and its very serious results in deterioration of health are well-known facts. Within the past year consideration of the whole subject has resulted in the initiation by His Excellency Lord Ronaldshay, Governor of Bengal, of an organised campaign for control and prevention of the disease. The work has been undertaken by Dr. C. A. Bentley, Sanitary Commissioner, with the assistance of Dr. Borland McVail, Dr. R. G. Griffin, and Dr. S. P. Gupta. One of these officers has charge of the organisation in respect of mills, factories, and railways; another in respect of tea-gardens and coal-mines; and the third in respect of municipalities and police in Burdwan. The nature of the crusade can be illustrated by reference to the first of the three sections—that of mills and factories. The prime object was to secure the interest and support of both employers and employees. In March, 1919, there was held a meeting of superintendents and managers of the mills, together with medical men and senior employees. The gathering was presided over by the chairman of the Jute Mills Association, and was addressed by Dr. Bentley, who pointed out the prevalence of the disease and its effects, not merely direct in the way of ill-health, but also financial in the loss resulting from deterioration of physique amongst mill-workers. It was explained that the line of attack would be by the institution of laboratories at which the necessary microscopical examination of infected material could be made, and treatment adopted for those found to be affected. This proposal was favourably received, premises for a laboratory were provided at one of the mills and work has been begun.

In initiating the campaign account had to be taken of the suspicions and susceptibilities of the workers, who, it was found, were apt to suppose that discovery of their being infected with the disease would lead to dismissal from employment. At first the scheme was confined to microscopic examination to ascertain the degree of prevalence of ankylostomiasis, and even this had to be carried on with discretion. In the early examinations, only about 50 per cent. were found infected, but this was probably due, in part, to the inexperience of some of the microscopists, as indicated by the fact that in one mill the percentage of positive cases rose from less than 50 in April to over 70 in July and August. Treatment as a sequence to diagnosis was gradually instituted, and, as weeks passed, reluctance to accept it diminished. For some months only males were dealt with, but later on a few females were treated, and the number of these also is increasing. As the scheme extended from one mill to another, its details became modified, and instead of endeavouring to ascertain the percentage of prevalence, attention was concentrated on examination and treatment of cases which the mill doctors knew to be suffering from debility. In that class the cause of debility was in some mills found to be hookworm in more than 90 per cent. of the cases. In addition to the training of the laboratory staff, mill doctors were also brought into the scheme and have aided in the work. On one of the railways two laboratories have been opened under the charge of Dr. T. H. Bishop, working in connexion with the central department, and various difficulties are being overcome. At one mill the workers belonging to the weaver caste were the subject of investigation, and though these regularly wear boots and are therefore less exposed to risks, 35 per cent. were found infected.

---

[1] The American Journal of Syphilis, January, 1920.

Amongst mill-workers the prospects of success or failure of a crusade must obviously depend in great measure on the goodwill, or indifference, or opposition of those responsible for the management of the mill, but the immense importance of the treatment should surely suffice to enlist cordial support. Now that the schemes have been fairly initiated, the work should be taken up by the mills themselves in respect of the provision of apparatus and staff, as, even where labour is plentiful, it is important that the standard of health should be high. Until the natives can be educated into cleanly habits, so that the ground shall not be constantly the place of deposit of infective material, the action taken by those engaged in the crusade will have to be constantly maintained at a high level; under spasmodic activity the benefit is likely only to be temporary, as the conditions favouring ankylostomiasis will continue to provide new cases of the disease or renewed infection of those who have already been cured. The ultimate object must therefore be the establishment of sanitary habits, and if that is accomplished there may then, but only then, be entertained a hope of relaxation of the efforts being made. At present, of course, extension of the operations of the scheme is the urgent requirement. In the meantime, the scope for direct individual benefit by means of treatment of individuals is almost unlimited. India is working towards an increasing degree of self-government, and if Bengal is by-and-by to take its place as a centre of industrial activity—if, for example, shipbuilding is to be established on a great scale on the Hoogly—it is of the first importance that the population from whom the class of workers would have to be drawn should be protected against this definitely preventable infection.

RECENT FRENCH WORK ON SYPHILIS.

IN the *Paris Médical* for March 6th Dr. Milian gives an excellent review of recent work on the subject of syphilis. Levaditi and Marie have supported the contention that general paralysis is due to a special variety of treponema by means of further animal experiments. A longer incubation period is required for the development of lesions in the rabbit after inoculation with the "neurotropic" virus than that required after inoculation with the "dermotropic" variety. The appearance of the lesions is, moreover, somewhat different in the two cases. Inoculation with the dermotropic virus produces typical infiltrated nodules, whereas the neurotropic treponema causes widespread and superficial lesions, surrounded by a zone of infiltrated skin. The two varieties of virus would appear also to differ in their virulence, the injection of the dermotropic variety into monkeys being followed by the appearance of a typical chancre, whereas the neurotropic treponema (after passage through a rabbit) is non-pathogenic to monkeys. The authors explain these findings by means of the hypothesis that the treponema of general paralysis is a different variety to that found in syphilitic lesions of the skin, mucous membranes, and viscera. Dr. Nicolan, of Bucarest, has made extensive examinations of the cerebro-spinal fluid during the primary stage of syphilis, and has found changes occurring as early as the fifteenth day. As a rule, however, these changes were not noted before the third week. In connexion with these changes he calls attention to the importance of noting any inequality of the pupils that may be present. Out of 18 cases of primary syphilis *with* spinal lymphocytosis 11 showed inequality of the pupils, whereas amongst 33 primary syphilitics *without* cerebro-spinal fluid changes only 5 instances of unequal pupils occurred. Lacapère, Fournier, and Guenot have all contributed to the subject of the prevention of syphilis by means of prophylactic injections of arsenobenzol. Azémar has reopened the question of the administration of arsenobenzol by the rectal route. He has shown that it is rapidly absorbed by the detection of a considerable quantity of arsenic in the urine two hours after the enema has been given. The quantity of arsenic found in the urine increases up to the third day, and then disappears by the sixth. As compared with that observed after an intravenous injection the elimination is later, more abundant, and less prolonged. In the case of an intravenous injection traces of arsenic may still be found in the urine 15 days after the injection. The therapeutic effects of intra-rectal medication are therefore less rapid, less profound, less constant, and less durable than those obtained by the intravenous route. Rectal injections of arsenobenzol may possibly be of use during the latent period of syphilis, or as a preventive measure. They are not advisable when active clinical manifestations of syphilis are present. Sicard recommends the administration of "914" in daily doses of 0·1 to 0·2 g. until a total of 8 or 9 g. has been administered. He considers that by this method the ill-effects occasionally following the administration of this drug are minimised, and recommends its employment in cases of hemiplegia. Dr. Milian discusses the question of jaundice occurring during a course of arsenical treatment, and comes to the conclusion that in the majority of cases the jaundice is the result of the disease rather than of the remedy. He points out that similar cases are observed during treatment with mercury alone. Arsenical dermatitis has likewise been the object of careful study by the same author. Two different categories of dermatitis have been distinguished. The first occurs about nine days after the first injection, and appears as an erythema, scarlatiniform, morbilliform, or polymorphic in type. The second occurs towards the end of course, when the patient has received a quantity of arsenic, and is in the nature of a dermatitis exfoliativa. The latter is of more serious import and necessitates the suspension of any further treatment with arsenic.

IN HONOUR OF DR. WILLIAM WELCH.

Dr. W. H. Welch, professor of pathology in the Johns Hopkins University, Baltimore, reaches his seventieth birthday this month, and the medical profession of America consider that the occasion ought not to pass without some expression of admiration for one who has long stood in the position of a leader. To many of his friends it has seemed that a worthy expression of affection would be the preservation in suitable form of the chief contributions from Dr. Welch's pen. These are scattered through a great variety of publications, and are more or less inaccessible. It has accordingly been decided to bring together and to publish in three volumes his papers and addresses, which strikingly reveal the great part he has played in the development of medical science and medical education. To place the project upon a sound financial footing it has been decided to invite his friends and former pupils to unite in making possible the publication of his work. A set of three volumes will be issued by the Johns Hopkins Press, under the editorial supervision of a well-chosen committee, to subscribers at $16.50, which is less than the estimated cost. Each copy will be numbered and assigned in the order of subscription. The edition will be restricted to the number subscribed. The following distinguished members of the medical profession of the United States form the committee of publication: John J. Abel, Lewellys F. Barker, Frank Billings, Walter C. Burket, William T. Councilman, Harvey Cushing, John M. T. Finney, Simon Flexner, William S. Halsted, William H. Howell, John Howland, Henry M. Hurd, Henry Barton Jacobs, William W. Keen, Howard A. Kelly, William G. MacCallum, William J. Mayo, Ralph B. Seem, Winford H. Smith, William S. Thayer, J. Whitridge Williams, Hugh H. Young.

THE summer session at the Brompton Hospital for Consumption, which begins on April 13th, includes a daily series of afternoon demonstrations, the aim of which is to present the student to the problem of tuberculosis systematically, and to give him an opportunity of seeing the results of sanatorium and other treatment and of discussing with the staff the causes of failure in this or that case. The teaching will not select rare or curious cases, but will concentrate on the ordinary case in all stages of the disease. Details will appear in our Medical Diary.

AT the election to the Council of the Royal College of Surgeons of England, to take place on July 1st next, there are three vacancies upon the body. Two of those retiring from the Council by rotation—namely, Sir Anthony Bowlby and Sir D'Arcy Power—will offer themselves for re-election; while the other Fellows who are candidates for seats are: Mr. H. S. Pendlebury, surgeon to St. George's Hospital; Mr. W. Thelwall Thomas, surgeon to the Royal Infirmary, Liverpool; Mr. J. H. Fisher, ophthalmic surgeon to St. Thomas's Hospital; Mr. F. J. Steward, surgeon to Guy's Hospital; and Mr. Victor Bonney, assistant obstetric surgeon to the Middlesex Hospital.

EXPERIMENTAL MEDICINE AND THE VENEREAL DISEASES.[1]

BY WILLIAM F. SNOW, M.D. CALIFORNIA,
CLINICAL PROFESSOR OF HYGIENE AND PUBLIC HEALTH, LELAND STANFORD JUNIOR UNIVERSITY SCHOOL OF MEDICINE;
AND
THOMAS A. STOREY, M.D. HARVARD.

IN this discussion, related to the so-called venereal diseases—syphilis and gonococcus infections—an attempt will be made to keep constantly in view their public health aspects. Mention of economic, social, or moral measures will be limited to those which have some important bearing on the prevention of these diseases, and likewise references to education or methods of treatment will stress the benefit to the public rather than to the individual. It is necessary at the outset to have such an understanding, because the details of combating these diseases are necessarily concerned largely with that No-Man's Land between the views of the old-time physician who says there is nothing to do about venereal diseases except treat patients who have intelligence enough to apply, and the old-time moralist who says that these diseases are essentially a check upon sexual immorality and that any measure should be opposed which in the least degree may be interpreted as lessening the maintenance of moral standards. The limitation of this paper in this way does not imply, however, that sex-education, moral and religious training do not have on their own account social values far more important to the welfare of the nation than the complete elimination of venereal diseases could possibly have. The paper is still further limited largely to the experimental medicine phase of developing new methods of combating these diseases.

The Dissemination of Syphilis and Gonorrhœa.

A review of our knowledge upon which may be based a study of the prevention of venereal diseases shows that syphilis and gonorrhœa in their various medical and surgical manifestations are actually or potentially communicable diseases due to identified organisms; the methods of transmission are known, and practical laboratory and clinical technique has been worked out for diagnosing each of them; they are widely prevalent throughout the world among individuals of every race, sex, age, and condition of people; they find their chief opportunity for dissemination in the intimate personal contact of infected individuals with other individuals who are susceptible; they are largely but not exclusively transmitted through the promiscuous sex relations defined as prostitution; recent methods of therapy make practicable the shortening of the period of infectivity and improve the chances of ultimate recovery of the patient submitting to early and thorough treatment; once contracted, they may run their course to practical recovery, or a resting stage, with or without medical assistance, but under present conditions an unknown and large percentage of those infected never completely regain their health or cease to be carriers, and therefore are a continuous menace to society. Syphilis in its early stages is especially a public danger, while in its late manifestations the damage is largely confined to the individual himself. Gonorrhœa, on the contrary, while a public danger at all times, is particularly damaging to the individual in its early acute development, and later becomes an insidious danger to those intimately associated with him, especially within his home and family.

In a word, we know the cause of these diseases; we know that human "carriers" afford their chief mode of dissemination; we know that in prevalence and injury to the people they are not outranked by any others of the communicable disease group; and we know that theoretically we should proceed to apply these facts exactly as we apply the similar facts concerning other preventable diseases. Reduced to simplest terms this means the adoption and enforcement of (1) measures for the discovery, treatment, and control of individuals already infected, (2) measures for the elimination of conditions of environment favouring the dissemination of the infection, (3) measures for the protection of individuals not yet infected.

---

[1] A paper read before the American Association for the Advancement of Science, St. Louis, Mo., on Jan. 2nd, 1920.

Support of Public Opinion Required.

In practice the application of such a programme cannot proceed until the details of effective measures have been worked out and demonstrated, and the support of public opinion for an active campaign has been secured. The public is interested in the conservation of health as an asset in the world's work, and looks upon the eradication of any disease merely as one of many efforts which collectively may aid Society in guaranteeing "life, liberty, and the pursuit of happiness" to its members. An individual having a programme for the prevention or control of a disease must be prepared to undergo most searching interrogation as to the soundness of the programme, and must compete for recognition with others who have different plans for social progress, not only in the matter of disease prevention but in matters which may be of far greater importance to civilisation. He may present the most complete and statesman like programme and still accomplish nothing to protect his great grandchildren from the diseases against which he contends unless he popularises his knowledge, pioneers the way for community action and perpetuation of the initial effort. When the public does wake up to the possibilities of prevention it desires to do everything at once and get the job over with; from battling to get their programme recognised, those promoting a special campaign find themselves battling to have unsettled questions laid on the table until a careful decision as to policy and method can be made. All public health progress has followed this course.

The pendulum has swung back and forth between general ignorance and widespread interest, foolish indifference and unwarranted fears, impatience over slow progress in applying old measures, and confusion over continued controversies relative to new measures.

Inconsistencies with Regard to Venereal Disease as a Health Problem.

In the case of syphilis and gonococcus infections the public health problem has been theoretically more hopeful and practically more difficult than for any of the others. The basis for control of syphilis and gonococcus infections must be the same in principle as that for the control of other communicable diseases. This must be recognised, else we will fail. The medical profession as well as health officers and military authorities are quick to endorse this point of view, but slow actually to put it in practice. To illustrate: in small pox we use every means to diagnose and treat the patient for his own sake, and promptly report the case to the health officer in an effort to protect the community through such measures as he may deem it necessary to take; in syphilis, when the same individual comes to us, we talk much of the Hippocratic oath, of personal liberty of the patient, of the tragedy of a broken home if the patient's wife should learn of his disease—the plain fact is that public opinion has not been forming for generations in support of a genuine public health programme against syphilis as it has against small pox, and we have not had the courage fully to apply our knowledge until that opinion is formed. In diphtheria we not only report our cases, but we follow them into the home and the school or business, and examine their associates for the detection of other cases or carriers—if we were sincere in our belief that the venereal diseases must be attacked as a public health problem rather than as an adjunct to a moral one, we would work out practicable measures to compass the same results which we achieve in diphtheria. In malaria we have long advocated the elimination of swamps and the protection of the uninfected portion of the population from the bites of malaria carrying mosquitoes, but in venereal diseases we not only withhold from the health officer information of known foci of infection, but encourage him to state that he has no interest in the elimination of red light districts and other recognised centres for spreading these diseases. Here again the fact is that we know better but have not urged our officials to assume leadership in solving such a complicated and disagreeable problem. In tuberculosis, we take infinite pains and spend millions of dollars to advise, treat, and give after care to persons who are found to be infected; yet in syphilis and gonorrhœa cases even our best clinics have made comparatively little headway in following up their patients and keeping them continuously under treatment, and our physicians as a rule either will not treat such cases at all, or feel no responsibility for keeping them under treatment and instructing them concerning the protection of others from infection. Such inconsistencies between the theory and practice of regarding the venereal diseases as a health problem are due to failure in the past to develop public opinion in support of a rational campaign; but much has now been done in this direction, and the demonstration of practical measures during the past two years in every part of the United States has prepared the way for rapid progress. Untreated cases are the principal source of infection and these cases may be classified into those who never seek treatment, and the "missed" cases among those who have presented themselves for medical diagnosis and treatment; the uncured cases are next in importance; and our failure to follow up contacts with known cases constitutes an additional important factor, as does likewise our failure to secure the diagnosis and treatment of suspected cases and carriers. For 20 years individual workers and volunteer organisations have endeavoured to devise ways and means of reconciling theory and practice in combating these diseases. Finally, the American Social Hygiene Association, the Oregon Social Hygiene Society, the Young Women's Christian Association and other agencies joined in an appeal to Congress to establish a federal board empowered to develop research, educational, and administrative facilities for concerted attacks upon this problem throughout the nation. The United States Interdepartmental Social Hygiene Board was created, and simultaneously by the provisions of the same Army Bill a division of the United States Public Health Service was established to encourage and direct the campaign for the gradual eradication of the venereal diseases. Through these federal departments cooperating with the army, navy, Bureau of Education, Children's Bureau, and other Governmental agencies, the United States Government has inaugurated within the last year and a half the most nearly complete programme ever undertaken for the control, prevention, and eradication of gonorrhœa, syphilis, and chancroid. This programme involves a search for additional accurate information concerning the causes, carriers, prevention, treatment, and control of these diseases; it includes measures for the appropriate distribution of this information; it provides for the development of sound educational methods of sex education; it supports medical measures for treatment, prevention, and control in every State in the union; and it supplies plans and resources for the employment of social measures for protection against, and for the care of persons with, these diseases. In short, the Government has provided financial resources and the administrative machinery for promoting—

(1) Scientific research for better medical methods of treatment and prevention.

(2) Educational, sociological, and psychological research and demonstration of better educational methods in the prevention of venereal disease.

(3) The application of medical measures for the prevention, treatment, and control of these diseases.

(4) The utilisation of social measures for protection against and care of carriers of venereal disease.

Since the initiation of this composite programme the Government has expended something over $3,500,000 and secured thereby the expenditure of an even larger sum by State and local governments and volunteer agencies.

Government Support for Research Work in the United States.

The United States Inter-departmental Social Hygiene Board has appropriated over $120,000 to 20 American colleges or universities for the purpose of supporting 33 separate researches to be carried out in the scientific laboratories of these institutions. There are now over 100 men and women at work upon these efforts to perfect better medical treatment and prevention measures for gonorrhœa, syphilis, and chancroid. Some of the scientific applications now being made for the control of these diseases show a striking similarity in their details to the applications of scientific knowledge that have been made for the control of malaria and yellow fever. In the control of these diseases we have accomplished dramatic and spectacular results by the use of screens and of sanitary procedures for draining swamps and oiling water, thus closing off the feeding-places and destroying the breeding-places of the mosquitoes that carry these diseases. To-day, under the provisions of the United States Inter-departmental Social Hygiene Board, we are working over plans for devising analogous social and legal "screens" that will keep the human carriers of syphilis and gonorrhœa away from their victims and eliminate the conditions which breed them. Referring again to the past by way of introducing the present, an illustration may be drawn from the remarkable scientific research on the synthetic production of the so-called "606" for the treatment of syphilis, one of the most gratifying and scientifically satisfying achievements of modern pharmacology. Very recently the United States Inter-departmental Social Hygiene Board made appropriations to American scientific laboratories for the synthetic production of new compounds for the treatment of gonorrhœa and for some much-needed improvements on the arsphenamine treatment of syphilis. The Brady Urological Institute of the Johns Hopkins Medical School has already produced a new mercurial compound as a result of an investigation that combined a brilliant scientific calculation with a practical and satisfying therapeutic demonstration. This product, mercurochrome "220," carries the qualities of deep tissue penetration, effective bactericidal properties, and a non-toxic effect upon tissue cells, and would seem to represent an effective and practically useful application of scientific knowledge to the treatment of gonorrhœa. Time alone, of course, can tell just how useful this drug may be.

Experiments of a similar character, supported in part by the United States Inter-departmental Social Hygiene Board, are being carried on for the production of other synthetic compounds at the Johns Hopkins Medical School, the Medical School of the University of Wisconsin, and the University of Nebraska. The Harvard University Medical School investigations are being made on the properties contributary to the toxicity of arsphenamine, neoarsphenamine, and analogous products.

Students of bacteriology and parasitology have in the past patiently studied the different strains of some of our better-known pathogenic bacteria and protozoa, thus giving a rational basis for a scientific investigation of their relationship to the human host. Scientific investigations are now being made at the instance of the Board in several American medical laboratories for the purpose of charting the gonococcus group. Serological studies of this group are being carried out in the Cornell University Medical School, and at Yale University there is being made an intensive study of methods for the isolation and identification of the gonococcus with a view to determination of the homogeneity of strains and their ætiological relationships.

The case-histories in which arsphenamine has been used indicate that this arsenical compound has toxic properties, which under certain circumstances are of serious danger to the patient. Because of this fact newer arsenical compounds have been developed in the hope that the product would exhibit less toxic properties. The nature of the toxicity of "salvarsan" and analogous arsenical compounds is a matter of extreme importance. Investigations for the identification of properties that contribute to the toxicity of these products are being carried out in the Harvard University Medical School. In connexion with these investigations, although in another laboratory—the Massachusetts State Psychiatric Institute—there is now being developed an investigation for the detection of changes effected in the central nervous system by various methods of neurosyphilitic therapeutics, complete central nervous systems of individuals treated intravenously, subcutaneously, and intraspinously having been secured.

Investigations Concerning the Families of Syphilitic Patients.

The family of the syphilitic presents problems that are in a great many respects very like those encountered in the family of the tuberculous case. The field for investigation is, to say the least, as great and as promising as was the field in tuberculosis. A sociological, psychological, educational, and medical investigation is being carried on now at the Massachusetts State Psychiatric Institute, Boston, covering the families of the syphilitic patients who have come to that institution in recent years, and with whom the officials of that institution have a very satisfactory mutually useful working agreement. These investigations will very likely secure important information concerning the acquirement of syphilis by the members of a family, and should develop more effective methods of group instructional hygiene for the avoidance of such infections. Furthermore, these researches should lead to a much clearer and more appropriate social programme for the protective, preventive, and reconstructive hygiene of these diseases.

Specialisation and Scientific "Team-Work."

The progress of science has been accompanied by a very definite specialisation of scientific investigators. While this specialisation has led to scientific advances that could have been achieved in no other way, it has been accompanied by an intellectual separation of scientific investigators that has made it increasingly difficult to utilise several highly specialised lines of investigation for the purpose of accomplishing a particular composite result. The synthetic chemist, the physiologist, the pathologist, and the pharmacologist are specialised scientific students whose joint activities would often be of very much greater practical value in medicine or in preventive hygiene if their scientific investigations could be made a part of a prearranged correlated series of researches. With this purpose in mind a combination research programme has been established whereby synthetic chemists of Northwestern University and the University of Illinois have undertaken to develop new compounds carrying arsenic which are to be tested out therapeutically in the Laboratory of Pharmacology and Therapeutics of the University of Wisconsin. This combination brings together three powerful laboratories in three great universities, and should result in a piece of very effective scientific "team-work." It is impressive to note that these scientific experts, who were so deeply concerned yesterday with the discovery of powerful chemical offences and defences against our human enemies, are to-day applying their brilliant resources for this discovery of chemical defences against our pathogenic enemy, the treponema. It is to be hoped that the discoverer of "Lewisite" and his present associates will find a chemical agent that will defend us with equal success against syphilis.

There is not time here to present the details of all the investigations which have been authorised by the United States Inter-departmental Social Hygiene Board or are being carried out independently, but for purposes of the association's proceedings there has been included an epitome of them at the end of this paper.

The purpose of this discussion is primarily to stimulate the interest of the members of the American Association for the Advancement of Science in two directions: (1) the development of public opinion in support of applying the knowledge which we already have, and (2) the acquiring of new knowledge applicable to the reduction in prevalence of syphilis and gonococcus infections, not merely knowledge of laboratory or chemical technique, but sociological and particularly psychological and psychiatric knowledge.

Social and Psychological Aspects

In combating syphilis not only must the social aspects of the problem be dealt with but the moral and religious as well. It has been pointed out that yellow fever would not now be essentially a matter of the past instead of one of the most dreaded of communicable diseases of the present had the epidemiologist not supplemented by field observations the evidence of pure science and developed practical methods of dealing with the reduction of exposures to the bite of the insect carrier of infection. Likewise it may be repeated that the epidemiologist may not hope to succeed against syphilis unless he recognises the human carriers of infection—the woman who practises prostitution and the men who seek sexual relations with her. It may not be considered strictly scientific to compare these so called human carriers with the mosquito hosts of such diseases as yellow fever and malaria, but the general analogy holds. It may fairly be maintained that were prostitution to cease for a generation syphilis would be brought under complete control, and what is true of syphilis is in large measure true of the gonococcus infections. It is the duty of the scientist to examine carefully the possibilities of eliminating these human carriers of the venereal diseases. Sir William Osler once said to some of us by way of illustrating the necessity for an ever present freshness of view point in studying a medical problem: "You must bear in mind that there are three ways of eradicating malaria, all of which are theoretically equally effective: (1) you might kill all the malaria parasites, (2) you might kill all the mosquito carriers, (3) you might kill all the people." This observation applies to the eradication of syphilis, but it happens, as in the case of malaria eradication, that we do not wish to kill all the people, and we have not yet devised ways of killing all the parasites or of eliminating all the carriers. Much may be expected, however, from a study of both the second and the third methods. Already enough is known to ensure an enormous reduction in the prevalence of venereal diseases if we but apply our knowledge, but we need more social, economic and psychological facts before a complete programme can be formulated. The mistakes of the past must also be studied. For example, it was natural that the public health administrator should propose to identify all the suspected carriers and examine them. This has been done with signal success in diphtheria, people by the hundreds or by whole communities have been subjected to examinations of their nose, throat and ears, which are no more difficult from the point of laboratory and clinical technique than the examination of an equivalent number of person for syphilis. But the latter's selection of the mucous membranes of the genito urinary system as the principal site for its initial lesions completely alters the practicability of applying the methods used in dealing with infections entering the body through the membranes of the mouth and throat. Conventions of clothing, questions of morality and modesty, besides the characteristics of the disease, all render it necessary to adopt other measures. The effort has been made to examine those who were known to be engaged in prostitution but the men have always successfully objected to being examined, and only those women who could not escape the registration or other police machinery set up could be brought under the regulations. Thus there has never been more than a small percentage of the entire number even of the women under examination, and superficial examinations of a few women without any examination of their male companions has not proved effective. Under the exceptional circumstances of isolated military troops subject to frequent examination, simultaneously with examination of women in segregated houses visited only by the soldiers, such examinations for male and female carriers have claimed measurable results, but the essentials of complete control of both sexes have not been practicable in civilised countries in times of peace, or even during war for large bodies of troops.

Only recently has society become willing to consider the application of law, social protective measures recreational and educational facilities to the prevention of exposure of its members to the venereal diseases. The analogy between screening the uninfected portions of a population against the mosquito carrier of malaria and screening them against the human carrier of venereal diseases through setting up a protective screen of social measures for combating prostitution is just becoming apparent to large numbers of citizens. There was a time in the history of preventive medicine when the public were taught to hang pieces of asafœtida about their necks or to put saucers of carbolic acid under the sick bed. No doubt these measures did some good in the same way that our quarantine signs placed before the quarters of scarlet fever cases do some good now in inducing the well to keep at a distance from the known sick, but such measures have been largely replaced by more effective and more intelligent methods. Similarly, the scarlet letter and the painted lady labels have in their time served as indications of the desire of the public to have the well kept away from the morally and physically sick of vice districts. But, likewise, these crude and cruel methods are giving way to more intelligent and far more effective measures which take cognisance of a well rounded programme for moral medical, and social rehabilitation of those who are spreaders of venereal disease and immoral practices. Just as joint investigations on new medical measures are being promoted, so joint social and moral welfare investigations are being encouraged.

Conclusion

The United States Inter departmental Social Hygiene Board, coöperating with the Division of Venereal Diseases of the United States Public Health Service and State Boards of Health as official bodies and with the American Social Hygiene Association and its affiliated branches as voluntary agencies is endeavouring to promote a statesman like effective campaign to relieve the citizens of the United States from the ravages of these great unconquered disease enemies. You who hold influential positions in university and civic organisations are in a position to bring about for concerted attack on the venereal diseases, an allied army of scientists, social workers professional men business men, and citizens analogous to the coalition of our armies under Marshal Foch. Until that was accomplished we could not win the world war; until this suggested coalition of scientific, social, political, and religious resources of the nation takes place, we may not hope for the brilliant results which are possible in conquering the venereal diseases. Men of science and medicine particularly are challenged by humanity to give their aid to this great disease battle, which must go on for generations, as the fight against small pox has gone on if we are to do our duty by the succeeding generations, for whom we are conserving our forests and water power and our other natural resources.

The paper concluded with the epitome of the scientific investigations now being carried on in America with the assistance of the Social Hygiene Board which appeared at length in THE LANCET of March 13th, pp. 622–624.

MEDICAL INSPECTION AND TREATMENT OF SCHOOL CHILDREN IN SCOTLAND.—By an Order in Council, the powers and duties of the Scottish Education Department in regard to the medical inspection and care of children have been transferred to the Board of Health. A memorandum issued by the Board points out the progress already made and the necessity for fresh interest and advance. Special emphasis is laid on the need for preventive work and attention to hygiene of schools and pupils, for physical education and training, the inculcation of sound habits the teaching of the responsibility of the individual to the community, and the adequate treatment of various ailments. Emphasis is also laid on the need for cooperation between the education and health authorities in the interests both of economy and efficiency, and it is pointed out that the same officials may with advantage act for the two authorities and that the same premises may be used. Education authorities are being asked to submit comprehensive schemes of medical inspection and treatment as soon as possible.

MEDICINE AND THE LAW.

Rex v. *Holt.*

THE Court of Criminal Appeal had recently before it the case of F. R. Holt, who was convicted of the murder, near Blackpool, of a woman with whom he had been intimate. The facts have been so widely published that they need not be gone into here. An unusual feature of the case was an attempt on the part of the defence to prove an alibi, and as an alternative defence to show that at the time when the crime was committed Holt was insane, as insanity is defined for the purposes of the criminal law. As to the alibi and any question of whether Holt in fact shot Mrs. Breaks on Dec. 23rd, 1919, on a sand dune near Blackpool, little or nothing was heard in the Appeal Court. Among the grounds of appeal it was argued that evidence had been wrongly admitted upon points not connected with the plea of insanity, but the court was not satisfied as to any of the objections thus raised, and apart from them the main question of the condition of the prisoner's mind when he committed the act of murder was argued at length. Further than this, fresh evidence as to his mental condition was tendered and allowed to be given. Any objection on the part of the Crown was withdrawn at the suggestion of the Lord Chief Justice, who pointed out that in the circumstances the court had a discretion to admit fresh evidence. Lord Reading was further of the opinion that it was desirable both from the point of view of the Crown and in the public interest that such evidence should be sifted in open court. The fresh witnesses showed that Holt had had a female cousin certified and confined in a private lunatic asylum, and that his paternal grandfather had suffered from delusions. A medical man who in the month of December had played cards with him had noticed his lack of power to concentrate his mind upon the game. This, however, was shortly after four days spent with Mrs. Breaks and the prisoner had been a winner at whist, poker, and bridge. More important medical evidence was given by Dr. B. Day, who had treated him in 1916 or early in 1917 for syphilis in its secondary stage, and had considered him then to be suffering from shell-shock. Dr. Day's application for a lumbar puncture to decide the presence or absence of general paresis was refused. In cross-examination of this witness it was mentioned that Holt had since been examined for insurance apparently without syphilis being detected. Two other medical witnesses spoke of conditions observed in 1915 and 1919, and Dr. D. Blair, called as an expert who had heard the evidence given in the Court of Criminal Appeal, was of the opinion that Holt was suffering from delusional insanity before the date of the murder, and that at the time of the murder he was suffering from general paralysis of the insane. Dr. P. Smith was of the opinion that Holt suffered from delusional insanity and was not of sound mind on Dec. 23rd, but that the indications were not manifest before Dec. 25th. In an argument founded upon the evidence, of which the above is a bare outline, and upon that given at the trial, where at first an attempt was made to show that the prisoner was unfit to plead, Sir E. Marshall Hall, K.C., sought to go further than the well-known rule in McNaughton's case. He argued in effect that if a man through no fault of his own had an impaired mental condition affecting his will power he should be deemed insane in respect of a crime from which normal will power would have enabled him to abstain. In other words, that, knowing the nature and quality of his acts and that he was doing wrong, he might be excused on the ground that he was urged by an irresistible impulse. In delivering the judgment of the court, dismissing the appeal on every ground, the Lord Chief Justice pointed out that the question of irresistible impulse had been left to the jury by Mr. Justice Greer at the trial, and that they had not accepted the contention of the defence as to its existence. On the question whether the Court of Criminal Appeal, having heard the fresh evidence adduced, should say that the prisoner was insane when he killed Mrs. Breaks, his lordship said that the new evidence had taken the case no further than before. It was based on hypothetical speculation and the rule in McNaughton's case must be observed. It was not enough that medical witnesses should say that they considered the prisoner insane.

Negligence and Compensation.

On April 1st, in Edinburgh, the First Division of the Court of Session gave judgment in two cases where compensation was claimed under the Workmen's Compensation Act, in which there was negligence on the part of the appellants. In both instances the persons injured were miners, and the circumstances were similar. Both had prepared blasting shots, and when these failed to explode up to time, the workmen returned within the period prescribed by the regulations as being unsafe, with the result that the shots went off and they sustained injuries, in one case fatal. Although there was negligence the court held that the appellants were entitled to compensation. The decision is of interest as it is apparently directly contrary to that given in the House of Lords on March 22nd in the case of Robertson *v.* Woodilee Coal and Coke Company, Ltd. Robertson was killed by an explosion in a pit, which resulted from his striking a match. His widow was held to be unentitled to compensation, as the case was one in which the doctrine of "added risk" was exemplified. The accident resulted from his own action, with full knowledge of the prohibition against it, and of the danger his action entailed.

The City Coroner's Views on Juries.

Dr. J. F. Waldo has issued his annual report as coroner for the City and Southwark for 1919, which, as usual, contains some interesting facts and statistics, accompanied by opinions candidly expressed with regard to them. It is to be observed that the 355 inquests held in the City and Southwark in 1919 exceed by 46 the corresponding number for 1918. This appreciable increase, presumably to some extent, is due to the greater volume of traffic caused by reviving business. At all events, it is greater in the City than in Southwark, 158 deaths having been inquired into in the former as against 132 in 1918. Investigation satisfied Dr. Waldo in 79 cases that inquests were not required. He states that post-mortem examinations were ordered in 85 per cent. of the inquests held by him. Among the comments upon matters concerning his office expressed by the learned coroner, we are a little surprised to read a rather confidently expressed recommendation that the power to hold inquests without juries, given by the Juries Act, 1918, should cease now that peace is established. We were under the impression that coroners were, on the whole, well satisfied with the less cumbrous procedure involved in the change, and that as they are obliged to have juries to take some of the responsibility off their shoulders in cases of suspected murder or manslaughter they would wish matters to continue as they are. We also believed, and, indeed, do believe, that intelligent and busy citizens liable to be summoned as jurors have no wish to see repealed an Act admittedly passed in the emergency of war. With those not intelligent and habitually without occupation, we should have thought that a coroner would gladly dispense. Dr. Waldo declares himself quite satisfied with the quality of the jurors whom he obtains in the City, and therefore maintains that a fairly intelligent jury, assisted and directed by a coroner, is a far better tribunal for the elucidation of truth than a coroner single-handed. This may be so to some extent and in some cases. As a rule, however, we believe the coroner, particularly the medical coroner, would be fully equal to the occasion. Juries of the more intelligent kind are obtainable in precisely those places where their members can least be spared from their business occupations. A man with a family to maintain, a business to reconstruct, and high prices and high taxes to contend with may still have to sit on a jury, if a case of possible murder or manslaughter requires his verdict. He would probably be glad to be freed even from this infrequent duty. He is ready, we feel confident, to leave the medical coroner, assisted by the medical witness, to clear the matter up.

AUSTRALIA

(FROM OUR OWN CORRESPONDENT)

The Claims of Returned Medical Soldiers

SOME feeling has been aroused over recent appointments to the staff of the Melbourne Hospital Of three vacancies for the post of physician to out patients, two were filled by applicants who had not done any military service The Returned Medical Officers Association, which in Victoria is a militant, not to say aggressive, organisation, has protested in the daily papers and by deputation to the hospital committee that an injustice has been done to some of its members, who were candidates for these positions, and demands that the appointments shall be reconsidered The committee at its last meeting confirmed the appointments There was a divided opinion as to whether the question should be reopened The appointments are made in reality by an advisory board, which is constituted by six members of the general committee, three members of the honorary staff, and three each from the University Council and the Faculty of Medicine This arrangement was substituted for the old election by vote of the subscribers, and so far the general committee has simply endorsed the recommendation of the advisory board without comment There is no reason to suppose that the selections were made in the instances referred to without the fullest consideration by this expert board, but the heartburning arose from the fact that an applicant who had been on the staff for some years in a junior position, and had done war service oversea, was unsuccessful Of the two gentlemen objected to by the malcontents, one was admittedly rejected as unfit for military service owing to X ray burns, and the other had a brilliant record as medical superintendent during the war time and through epidemics of meningitis and influenza The Council of the Victoria Branch of the British Medical Association forwarded a letter to the hospital committee asking that the principle of preference to soldiers should be strictly observed This letter is to be made the subject of a special meeting at which the whole matter will probably be reviewed, although there is no great likelihood that the appointments made will be disturbed One of the successful applicants has written to the press stating that, in his case, the methods of the Returned Medical Officers Association have nearly approached persecution

Medical Act of South Australia

The Medical Act of South Australia, which has just been passed by both Legislatures, is mainly characterised by changes in the powers of the Medical Board The registration requirements are now similar to those of Victoria, in that no diplomas other than those of the United Kingdom will be accepted unless issued by a country giving reciprocal recognition to South Australian diplomas The Board is also granted power to apply to the Supreme Court for the removal of names from the Register on various grounds, including being guilty in the Board's opinion of infamous conduct in a professional relation The fee for registration is £1 1s annually or a lump sum of £5 5s in perpetuity

Federal Committee of the B M A

At a meeting of the Federal Committee of the British Medical Association, held in Sydney early in February, discussion took place on the subject of extension of public health services, but it was almost entirely academic, and formulated in vague resolutions as to research and investigation into various topics such as infant mortality and the promotion of local "campaigns" against preventable disease It is a little absurd to waste time and money in establishing expensive commissions and research laboratories when the plain needs are staring everybody in the face Scarcely one provincial town or city in the whole of Australia has either an adequate water supply or system of sewage disposal No amount of research will suggest any defence while such elementary facts are neglected —A statement in connexion with the Medical Relief Fund for the benefit of returned men showed that £11,456 had been subscribed and £899 disbursed —In respect of the matter of Dr Eugen Hirschfeld of Brisbane, it was resolved "That the Federal Government be asked to deport all medical practitioners of enemy origin who have been interned during the war" —It was resolved to protest against the order of the Minister of Customs by which the importation of vaccines and sera was practically prohibited

Child Welfare

A conference on "Boy and Girl Welfare" has been held in Perth, and was addressed by a number of medical speakers A deputation, with Professor R J A Berry, of Melbourne as chief speaker, obtained from the Government a promise of an endowment of £2000 per annum for ten years for an institute for the study of feeble mindedness and the training of teachers

Personal

Dr T P Dunhill of Melbourne, who has been appointed Assistant Director of Surgery at St Bartholomew s Hospital, London, under the new teaching scheme of the London hospitals, is well known for his work on exophthalmic goitre, and served with distinction in France, being awarded a C M G Professor W E Agar, the newly appointed occupant of the chair of zoology in the University of Melbourne has arrived and Dr T L Apperly, the recently appointed lecturer on pathology, is expected shortly

March 1st

URBAN VITAL STATISTICS

(Week ended March 27th, 1920)

English and Welsh Towns —In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality which had increased from 15 6 to 17 9 in the five preceding weeks, further rose to 18 7 per 1000 In London, with a population of nearly 4½ million persons, the annual death rate was 19 3, or 1 5 per 1000 above that recorded in the previous week, while among the remaining towns the rates ranged from 10 7 in Coventry, 10 8 in Eastbourne and Cambridge and 11 1 in Hornsey, to 28 1 in South Shields, 32 2 in Wigan and 35 7 in Dudley The principal epidemic diseases caused 477 deaths, which corresponded to an annual rate of 1 4 per 1000, and comprised 214 from measles, 114 from whooping cough, 64 each from diphtheria and infantile diarrhœa, 18 from scarlet fever, and 3 from enteric fever Measles caused a death rate of 1 8 in Liverpool, 2 0 in Barnsley, 2 6 in St Helens, 3 0 in Wigan, 3 1 in Gloucester 3 3 in Cardiff, and 4 3 in Lincoln The deaths from influenza which had steadily increased from 66 to 312 in the eight preceding weeks, further rose to 392, and included 131 in London, 46 in Birmingham, 21 in West Ham, 14 in Liverpool and South Shields, 13 in Manchester, and 8 in Leyton and Plymouth There were 2101 cases of scarlet fever, 2043 of diphtheria, and 14 of small pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 2158 2066, and 8 respectively at the end of the previous week The causes of 44 deaths in the 96 towns were uncertified, of which 13 were registered in Birmingham, 4 in London, and 3 each in Blackpool and Sunderland

Scotch Towns —In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2¼ million persons the annual rate of mortality, which had increased from 14 2 to 17 8 in the five preceding weeks, further rose to 18 0 per 1000 The 414 deaths in Glasgow corresponded to an annual rate of 19 4 per 1000, and included 16 from influenza, 12 from measles, 5 from infantile diarrhœa 2 from whooping cough, and 1 each from enteric fever and diphtheria The 93 deaths in Edinburgh were equal to a rate of 14 2 per 1000 and included 2 each from measles and diphtheria and 1 from infantile diarrhœa

Irish Towns —The 190 deaths in Dublin corresponded to an annual rate of 23 9, or 0 6 per 1000 below that recorded in the previous week, and included 11 from measles 10 from whooping cough, and 2 each from scarlet fever and influenza The 284 deaths in Belfast were equal to a rate of 35 9 per 1000, and included 30 from influenza, 6 from whooping-cough, 4 from infantile diarrhœa, 3 from measles, 2 from scarlet fever, and 1 from enteric fever

---

THE WELLCOME BUREAU OF SCIENTIFIC RESEARCH —The address of the bureau will, on and after April 15th next be 25, 26, and 27, Endsleigh gardens, Gordon square London, N W 1, Director in Chief, Dr Andrew Balfour

Correspondence.

"Audi alteram partem."

BIOGRAPHY OF SIR WILLIAM OSLER.

To the Editor of THE LANCET.

SIR,—Lady Osler has requested me to prepare a biography of her husband and I shall be most grateful for any letters or personal reminiscences, or for information concerning others who may possibly supply letters.

Copies of all letters, no matter how brief, are requested, and it is hoped that dates may be supplied if possible.

If the originals are forwarded for copy they will be promptly returned.—I am, Sir, yours faithfully,

HARVEY CUSHING, M.D.

Peter Bent Brigham Hospital, Boston, Mass.,
March 24th, 1920.

LIFE ASSURANCE AND GLYCOSURIA.

To the Editor of THE LANCET.

SIR,—The importance of the early detection of glycosuria cannot be exaggerated, and the fact that many cases of diabetes are first discovered during the preliminary medical examination is not the least of the benefits life insurance confers. To be fair to the individual on the one hand and not to expose the company to unnecessary risks on the other it is important that such examinations should be carried out with all the aids modern science affords, and I cannot help thinking that the methods for detecting grape-sugar in the urine and arriving at a diagnosis of diabetes mellitus described by Dr. R. T. Williamson in THE LANCET of March 27th must lead to the loss of many reasonably good "lives" by the companies and much unnecessary suffering and discomfort on the part of the proposers, as they will result in the rejection of many persons who are in the unfortunate position of passing reducing substances other than glucose in their urine. These are by no means as uncommon as is generally supposed. During the past year I can call to mind two cases of pentosuria, one of true lævulosuria, and several of pseudo-lævulosuria which had been rejected by medical examiners for insurance companies and told they were suffering from diabetes. The urine in each case gave a definite reaction with Fehling's solution, and yielded an osazone with phenyl-hydrazin, and although the pentoses do not, of course, ferment lævulose and pseudo-lævulose behave like glucose. So long as reliance is placed on one, or even two or three, routine qualitative reactions when examining the urine such mistakes in diagnosis and, what is worse from the patient's point of view, in treatment also will continue to occur. Seeing the ease with which sugar may now be estimated in the blood and the definite indications of defective carbohydrate tolerance which blood analyses yield, it is surprising that writers and medical experts on life insurance have not made more use of this delicate method to confirm the results of urinary analyses. I now place much more reliance on examinations of the blood than of the urine in the diagnosis and treatment of diabetes, and I would strongly urge the wider adoption of blood-sugar estimations. All the rejected cases referred to above showed a normal blood-sugar content, and after a test-meal the percentage of sugar in the blood followed a normal curve, showing that their carbohydrate tolerance was not diminished in spite of the presence of "sugar" in the urine.

Before concluding, may I say with reference to the letter by Dr. O. Leyton on Anæsthetics and Diabetes Mellitus in the same issue of THE LANCET that his experience regarding the effect of anæsthetics on carbohydrate tolerance in diabetes seems to have been unfortunate and, I think, unusual when a patient is carefully prepared for operation. Several of my diabetic patients have undergone serious operations and I have never found any diminution of tolerance to follow; in fact, in one case, where an abdominal tumour was removed from a woman, there was a considerable increase. Anæsthetics, particularly chloroform and ether, are dangerous for diabetics owing to the acidosis they induce, probably owing to their action as fat solvents and their effect on the liver. A couple of weeks on a fat-free diet with alkalies at the time of the operation will do much to minimise the risk.

I am, Sir, yours faithfully,

P. J. CAMMIDGE.

Nottingham-place, Marylebone, W., March 27th, 1920.

To the Editor of THE LANCET.

SIR,—In the valuable paper by Dr. R. T. Williamson on Life Assurance and Glycosuria in your issue of March 27th the writer states his opinion that when rejection of a proposer takes place on account of glycosuria the medical examiner should inform him of the cause, and explain its significance and the importance of treatment. Obviously the same principle would apply to many other causes of rejection discovered by an examiner, particularly to albuminuria and heart lesions. As Dr. Williamson states, it is a rule of many (I should say nearly all) assurance companies that no information as to the result of the examination should be given by the medical officer to the proposer. This is surely a salutary rule, for: (1) the medical officer has no power or right to forecast the decision of the board of directors, whom he advises; (2) all decisions should come from the officials of the company direct, who have other considerations than those purely medical to take into account; (3) a wily proposer will sometimes, on an inkling of an unfavourable verdict, go to another office and say he has not been rejected. Moreover, the examiner, if he followed Dr. Williamson's method, would be advising the proposer on his condition, which is no part of his duty and for which the proposer gives no fee. The rule of giving no information is therefore, in my opinion, a proper one, to be observed however with discretion in the spirit rather than the letter. Thus I have occasionally been asked by the company officials to hint to a certain proposer that advanced terms would probably be necessary, with the view of preparing his mind for them.

Has, then, the medical examiner no responsibility towards the proposer when he discovers some factor of importance, unknown to him, in his physical condition? Undoubtedly he has. How is this to be discharged? By advising him to consult his own doctor, advice which can be made slight or emphatic, according to the need and the proposer's temperament. In this way the duty of the examiner to the proposer, in respect of the knowledge he has acquired, is fulfilled, as well as that to the assurance office. A long and somewhat wide experience of assurance medical practice confirms the writer in the belief that this plan works satisfactorily.

I am, Sir, yours faithfully,

R. HINGSTON FOX.

Devonshire-place, W., March 29th, 1920.

To the Editor of THE LANCET.

SIR,—May I make one or two comments on Dr. R. T. Williamson's interesting paper in your issue of March 27th on this subject, which was discussed pretty fully in 1914 by the Assurance Medical Society, in connexion with a paper read by me, entitled "The Significance of (1) Diabetic Family History, and (2) Temporary Glycosuria in Life Assurance."[1] On this occasion I gave particulars of the family histories of 1143 policy-holders who had died of diabetes: their family histories (in the narrow sense of father, mother, brothers, sisters) showed deaths from undoubted diabetes in 41 cases—i.e., 3·6 per cent.—as against 1·05 per cent. in 1143 control cases of death from other diseases. Evidence was brought forward in favour of the views that there is a special form of family diabetes, tending to occur at an earlier age, and proving fatal more rapidly than the ordinary "acquired" type of the disease, and that this "family e occurs more commonly in the male than in the male

---

[1] Vide THE LANCET, March 7th, 1914.

was rather surprised to note that Dr Williamson de no mention of Benedict s test for glycosuria s reagent, the use of which Dr P J Cammidge ocated very strongly at the 1914 meeting, is particu y suited for routine use in life insurance work It ery simple in application, appears to be free from fallacies inherent in the use of Fehling s solution, t is sufficiently sensitive for all practical purposes

cannot help feeling that Dr Williamson is a little ere in his suggestions as to the treatment that ould be meted out by insurance companies to pro sers manifesting 'temporary glycosuria The con nsus of opinion at the meeting already referred to s in favour of the possibility of such a condition ng in many cases nothing more than a functional rangement, and not by any means the inevitable fore nner of permanent disease Indeed Dr Williamson s per contains several good examples supporting this w Why, then, should such cases not be taken at linary rates if subsequent repeated examinations ow no evidence of glycosuria and all other factors—e habits, family history, &c —are favourable?

A point of great interest is raised by Dr Williamson s ference to the rule of most companies that the dical examiner should give no information to the oposer as to the result of the examination In my inion, this rule is intended principally to prevent the aminer from telling the proposer that he is a horoughly good life, ' or some similar phrase For must be remembered that life assurance is some ing more than a question of medical examination, e examiner makes a recommendation to the com ny, but this recommendation is only one of the factors hough an important one) which determine whether e case shall be accepted as a first class life, rated up, rejected Hence it would be obviously undesirable r the examiner, as a result of his investigation, to ejudge the decision of the board, a decision involving her additional considerations I do not for a moment lieve, however, that any company would object its examiner telling a proposer whom he found to suffering from glycosuria that there was something out his water pointing to the desirability of his con lting his own doctor But to go further, as Dr lliamson suggests, and to enter into an explanation to the significance of the glycosuria and its prognostic portance, would be unwise and obviously undesirable om many points of view In any case, the proposer ould soon get an indication of the need for medical lvice when he found that his proposal had been jected deferred, or rated up as the case may be

I am, Sir, yours faithfully,
OTTO MAY

London W March 29th 1920

NTRAVENOUS INJECTION OF TARTAR EMETIC IN GUINEA WORM INFECTIONS

To the Editor of THE LANCET

SIR,—All who have experienced the baffling results which have hitherto met the futile attempts to rid atients of guinea worm and to check its crippling ffects will welcome the valuable contribution by Dr W S Macfie on the use of tartar emetic by intra enous injection in this distressing disease published in HE LANCET of March 20th It is much to be hoped hat the record of ten cases, in which the treatment met with greater success than has yet been attained by ny other remedy, will be followed by further observa ions and tests and that its value may be definitely stablished as the reliable cure of guinea worm

My own interest in the subject dates back to the years 902 and 1903 when, as medical officer to the Anglo French Boundary Commission in the Gold Coast and Ivory Coast Colonies, I was confronted with the harassing problem of how to deal with the *infection and to keep down the heavy percentage of invaliding from* this cause which occurred among some 400 native carriers and escort during the period of 16 months occupied by *the Commission s survey of the* western frontier of the Gold Coast *Filaria medinensis* takes its more familiar name, guinea worm, of course, from its *prevalence* among West African natives, and is known to them under such various titles as *Nfa* (Fanti) *Dippah* (Kurtta), *Kbule* (Mendi), according to the corresponding tribe language or local dialect Among the carriers of the survey expedition no fewer than 156 or 40 per cent , applied for treatment for guinea worm though undoubtedly a larger number actually suffered from the disease In the cases which came under notice the sites of emergence of the worm occurred as *follows* —

	Per cent		Per cent
Lower extremity (22 % being in the foot)	77	Scrotum (involving the testicle in 1 %)	4 5
Arm or hand	9	Back and buttocks	3 5
Abdominal wall	4	Face	1
		Penis	1

Towards the end of the expedition no fewer than 25 per cent of the carriers were more or less crippled by the infection Such a heavy incidence was *not* surprising considering the liquid filth they frequently drank when on the march, for the disease has long been known to be conveyed through drinking water infested by the minute water insect *Cyclops quadricornis* the intermediary host of the undeveloped worm

Multiple infection was by no means uncommon in 54 cases each patient carried from 2 to 10, in 12 cases 11 to 20, guinea worms, and one unfortunate sufferer *had as many as 25 worms scattered about in various* parts of his body at the same time! Guinea worm was responsible for 15 cases of synovitis, involving the knee joint in 8 the ankle joint in 5, and the elbow joint in 2 *cases* In 22 cases *incisions were necessary* to relieve cellulitis and suppuration in the arm leg back, buttock, abdominal wall or scrotum, and in 2 cases in which the testicle was invaded there were both hydrocele and suppurative orchitis

Efforts at treatment directed to destruction of the worm in situ by injections of a few minims of a 1 in 1000 solution of perchloride of mercury into the *protruding head, or into the* substance of the worm where it lay, subcutaneously, were tried with every possible precaution, but were not found a success under the conditions prevailing on the march Intense swelling of the part injected occurred, and eventually suppuration resulted, probably to be accounted for by local necrosis of the worm and the liberation into the tissues of still active embryos and irritating toxins of the worm The method was originally introduced by Emily, a French naval surgeon, who claimed remarkable success among his cases thus treated in hospital where proper rest to the part and every antiseptic precaution were available

Experience showed that the only reliable and safe method was to follow the long established custom of slow extraction by cold water douching of the exposed head and by attaching the protruding portion of worm to a small splinter of wood, subsequently each day, by very carefully making a turn of the piece of wood and thus slowly winding the worm out, avoiding any tension likely to break it, an accident inevitably followed by cellulitis or suppuration In addition to this laborious process of extraction, native methods of treatment which aimed at first killing the worm occasionally proved efficacious I have notes of two such remedies supplied by one of my hammock men, a native *medicine man* from Kurtta One consisted in the application of a paste composed of the leaves of a plant belonging to the *Euphorbiaceæ*, called *Addi* in the Kurtta dialect, pounded up *with the juice of fresh limes the other* was a Mahomedan remedy, prepared by crushing rock salt with the brown seeds of a common plant and mixing into a paste with oil It was asserted that the application of *either of these pastes* to the protruded head would result in the death of the worm in three days, when it was claimed that the dead worm could be extracted *in toto* by winding without risk of cellulitis or suppuration following A trial was made *of the former of the two native remedies* but results did not justify its further use

Until the recently advocated treatment by means of intravenous injections of tartar emetic, with the very promising results described by Dr Macfie in his paper there has been no advance in our knowledge of an effective cure for guinea-worm which will cut short the tedium and risk of slow extraction by winding in vogue for so many years. It is, therefore, greatly to be hoped that future trials of this apparently successful mode of treatment may result in its recognition as a certain and reliable remedy. I am, Sir, yours faithfully,

Savoy Hill, W.C., April 6th, 1920. J. GRAHAM FORBES.

THE PATHOLOGY OF HEAT-STROKE.

To the Editor of THE LANCET.

SIR,—The intimation in THE LANCET of March 20th by Dr. W. H. Willcox that he regards heat-stroke as an auto-intoxication, and the report of the observation of a leucocytosis in the cerebro-spinal fluid in the same condition by two French workers, both call attention to the fact that there seems to be rather a dearth of information as to the pathology of the condition.

The following notes, unfortunately from memory, may be of interest. Three cases occurring in men of the Guards' Division who had done a long march with full kits under a hot sun came under my care in 1917. One proved fatal in a few hours. At the post-mortem changes indicative of a far-reaching morbid process came to light. In addition to congestion of the cerebral vessels there were petechial hæmorrhages of the pia over the cerebral hemispheres, also of the pericardium, endocardium, and pleura; in one lung, though I cannot exactly remember where, there was a large and very definite area of congestion; there was also a slight increase of the pleural fluid.

In view of my previous entirely unfounded prepossession that the condition was solely a matter of the central nervous system these evidences of widespread damage were surprising. They certainly seem to confirm the suggestion that a toxic agency is at work. In both the cases which survived I found that the headache was relieved by lumbar puncture, which disclosed the fact that the cerebro-spinal fluid was in excess and under pressure. It was perfectly clear, but unfortunately, owing to a rush of work, no investigation of its cytology was undertaken.

I am, Sir, yours faithfully,
S. C. DYKE, M.B., B.Ch., D.P.H. Oxon.,
Assistant Bacteriologist, College of Medicine,
Newcastle-upon-Tyne.
Gosforth, March 20th, 1920.

VACCINES AND THE DIPHTHERIA CARRIER.

To the Editor of THE LANCET.

SIR,—The results obtained by Dr. J. L. Brownlie (THE LANCET, March 27th) in the treatment of the convalescent diphtheria "carrier," whilst of the greatest possible importance to the community in general, possess particular interest to workers at Guy's. Since the very early days of the present century it has been our practice to treat with vaccines all students and nurses who develop the carrier habit, and it was the results we obtained that prompted the following paragraph in "Serums, Vaccines, and Toxins" in 1910 (p. 107, repeated in the 1916 edition, pp. 135-176): "In such cases (i.e., cases in which the diphtheria bacillus remains domiciled in the throat, &c., for prolonged periods after the acute clinical symptoms have disappeared) a vaccine should be prepared from that strain of *B. diphtheriæ* actually infecting the patient, standardised and administered in doses of 5 to 10 millions at intervals of five to seven days. One or two injections are usually sufficient to ensure the disappearance of the bacilli from the local site of infection."

The opportunities afforded by a general hospital for the collection of statistical observations in this connexion are limited (for here we certainly do not total more than a score of diphtheria cases per annum), and we consequently welcome the confirmatory evidence on a figure basis so convincingly set out by Dr. Brownlie. My object, however, in writing this note is to point out the two important features in which our practice differs from that of Dr. Brownlie. In the first place, we are convinced of the superiority of the "autogenous" as against the "stock" vaccine, and in the second we insist upon washing the bacilli with several changes of normal saline before using them in the preparation of our vaccine. It is true that, when grown upon solid media, the diphtheria bacillus only forms a modicum of toxin, but strains vary in this respect, and neglect of precautionary measures may lead on occasion to the production of uncomfortable local reactions.

I am, Sir, yours faithfully,
Guy's Hospital, S.E., March 31st, 1920. JNO. EYRE.

LAVAGE OF THE CLOSED PLEURAL CAVITY.

To the Editor of THE LANCET.

SIR,—With great pleasure and approval I have read Dr. F. G. Chandler's paper on Oxygen and Air Replacement of Fluid in the Pleural Cavity in THE LANCET of April 3rd, but I would like to point out that lavage of the closed pleural cavity is not new, as Dr. Chandler believes. In a paper on Penetrating Wounds of the Chest, which I published, in collaboration with Major G. C. Shattuck, of Boston, U.S.A., in the *Journal of the Royal Army Medical Corps* of September, 1919, I made reference to lavage of closed chests. I quote my own words: "Irrigation of the pleural cavity can be performed through the aspirating needle on the syphon principle. Aspiration, sometimes assisted by what may be called 'aspiration-irrigation,' may be the means of effecting a cure when the infection is not too severe."

I am, Sir, yours faithfully,
R. BERTRAM BLAIR, M.B., F.R.C.S. Edin.,
Honorary Assistant Surgeon, Hull Royal Infirmary.
Albion-street, Hull, April 1st, 1920.

TUBERCULOSIS AND PENSIONS.

To the Editor of THE LANCET.

SIR,—Dr. John Guy's note on the Diagnosis of Tuberculosis in Recruits and Pensioners in your issue of March 27th deals with a subject of great importance and one which has been repeatedly discussed by the North of England Tuberculosis Society. My own experience is similar to Dr. Guy's, and my figures, compiled up to Dec. 31st last, show that of 313 ex-Service men who applied for sanatorium benefit 180 had had tubercle bacilli demonstrated in their sputum, and of the remainder 43 had signs of presumptive tuberculosis, while 90, or 28·7 per cent. of the total applicants, showed no evidence of any active tuberculous disease. Surely we have already a sufficient number of tuberculous patients without dissipating our funds on individuals for whom the sanatorium benefit provisions of the Insurance Act were not intended. If, and when, the proposed farm and industrial colonies and village settlements are instituted it is to be hoped that all applicants will be required to undergo a rigorous and searching examination to ensure that the facilities provided will be offered only to persons who are suffering from, or have recently suffered from, clinically recognisable tuberculosis. I am, Sir, yours faithfully,

W. H. DICKINSON,
Tuberculosis Medical Officer, Newcastle-upon-Tyne.
March 30th, 1920.

A WAR MEMORIAL TO BELGIAN DOCTORS.—From *Le Scalpel* for March 27th we learn that the project for a war memorial to Belgian doctors and pharmacists who died or were killed on active service is being energetically conducted by Dr. Clément Philippe. It is proposed to erect a monument in granite in the Place des Barricades at Brussels, near to the statue of Vésale. M. Cancel has been entrusted with its design and execution.

INFLUENZA IN ZURICH.—The epidemic of influenza in Zurich (population 210,000) has now come to an end. 14,534 cases have been reported since Jan. 4th. The total number for January was 1071; in February the records of the four weeks showed 2721, 4140, 3341, and 1899 cases respectively; in March the decrease was rapid, 866, 442, and 45 cases being notified in the first three weeks. The total number of deaths, mostly due to pneumonia, was 229, a mortality of 1½ per cent. In the Canton of Zurich (population 579,000) 141 cases of encephalitis lethargica have occurred, with a mortality of about 30 per cent.

The Services.

ARMY MEDICAL SERVICE.

Temp. Hon. Col. Sir J. Lynn Thomas (Major, retired, T F), relinquishes his temporary commission and retains the honorary rank of Colonel.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. J. G. Gill relinquishes the acting rank of Colonel.

Major C. R. L. *Ronayne relinquishes* the temporary rank of Lieutenant Colonel

Major and Bt. Lieut Col. F. D G Howell to be temporary Lieutenant Colonel whilst specially employed.

Temp Capt H. S. Davidson relinquishes the acting rank of Lieutenant Colonel.

Major L. A. A. Andrews to be acting Lieutenant Colonel.

Temp. Capt (acting Major) H F N. Scott relinquishes his acting rank.

The undermentioned relinquish the acting rank of Major Capts. E. C. Beddows, H E. A. Boldero, W P Croker; Temp. Capts. C. A Dottridge, R. Scott, O. J. Day, R L Crabb, P. Murphy.

Capt. G D'R. Carr is seconded for service with the Egyptian Army.

Officers relinquishing their commissions:—Temp Major T. M. Carter (Lieut.-Col, T.F Res) (granted the rank of Lieutenant Colonel); Temp Capt C. A. Masson. Temp. Capts (granted rank of Major) A. J Ferguson (acting Major), A W. Rattrie, E J Selby, L ap I Davies, Temp. Capts (retaining the rank of Captain) W H. Weir, C. H. Bryan, H. G. R Jamieson, R. R Watts, A. L Home, G. T Foster Smith, J. H Dove, B. G. Reynolds, T. W. Mason, C. L Miller, I W. Magill, C. B. Jones (acting Major), H. A. Haig, J. Buchanan, H R S Van Ryck de Groot, J. Wright, J B Fisher, J H. K Sykes, C Samut, C. E. W. Wilmot, A. W. Hendry, N. W. Gilchrist, C. G. Munro, H. B. Taylor, F. A. Osburn, R G. Struthers, F. P B MacTavish, F McG. Loughnane, J. Butterworth, J. W. Simon, T G. Dickson, T. D Morgan, F. W. Jackson, A. D. Moffat, F. W. Stuart, W. S. Booth, H. Somerville, Temp. Hon Capt B. E. Hawke (retains the honorary rank of Captain).

SPECIAL RESERVE OF OFFICERS.

Capt G Young relinquishes the acting rank of Major.

Lieut. W. Y. Eccott to be Captain.

TERRITORIAL FORCE.

Capt A. Sutcliffe is restored to the establishment.

1st *Southern General Hospital*. Major W. Kirkpatrick is restored to the establishment.

2nd Southern General Hospital: Capt A. G. T. Fisher is restored to the establishment.

TERRITORIAL FORCE RESERVE

Major C. A. Stidston, from 3rd North Midland Field Ambulance, to be Major

ROYAL AIR FORCE.

Medical Branch.—Wing Commander C. B. Heald relinquishes his temporary R A.F. commission on ceasing to be employed.

The undermentioned are transferred to the unemployed list: Capts I. M. Thomson and L. C Smith.

THE HONOURS LIST.

A very lengthy list of promotions in and appointments to the Most Excellent *Order of the British Empire* (civil division) for services in connexion with the war is published in the *London Gazette* of March 30th, and includes the names of the following members of the medical profession.—

ST. GEORGE'S HOSPITAL, MALTA, 1915–17 · REUNION DINNER.—A dinner will be held in London on June 10th for medical officers, sisters, and V.A D. nurses of the hospital, and other officers who were members of St George's Mess. Lieutenant Colonel A. de C. Scanlan, C.M G, *will* take the chair. Those desiring tickets (price 10*s*) are asked to write to Miss D. C Hare, M.D, 1, *Bickenhall Mansions*, W. 1, *or* Dr. Neill Hobhouse, 146, Harley street, W. 1, enclosing remittance, *before* May 20th.

Obituary.

GEORGE ARTHUR WRIGHT, B.A., M.B. OXF., F.R.C.S. ENG.,

EMERITUS PROFESSOR IN THE VICTORIA UNIVERSITY OF MANCHESTER; HONORARY CONSULTING SURGEON, MANCHESTER ROYAL INFIRMARY AND MANCHESTER CHILDREN'S HOSPITAL, PENDLEBURY; LIEUTENANT-COLONEL, R.A.M.C. (T.F.).

Professor G. A. Wright died on March 23rd at Sidmouth, where he had made his home on retiring from Manchester. He was in his sixty-ninth year, his death being the result of pneumonia after only a few days' illness, although he had for years suffered from asthma. In him surgical practice has lost a scholar, an investigator, and a master of his subjects.

George Arthur Wright was son of the rector of Vange, in Essex, where he spent his early years. He went to Marlborough and Oxford, taking a first-class degree in natural science. He graduated M.B. Oxf. from Guy's Hospital in 1877, becoming F.R.C.S. in the following year, and holding resident surgical appointments at his hospital. It was in the year 1880 that he began his career in Manchester as resident surgical officer at the old Royal Infirmary. Two years later he was elected honorary assistant surgeon with charge of out-patients, but 18 years elapsed before his turn came for promotion to the full staff. It was during this period that his original work was mainly done. He treated trigeminal neuralgia with much success by the injection of osmic acid. He was an advocate of early movement of joints near the seat of fractures. From 1882 on he was honorary surgeon at the Pendlebury Children's Hospital, he and the late Henry Ashby making a great name for this hospital and for themselves by their work. Wright produced a monograph on Hip Disease in Children in 1887, and in 1889 there appeared the first edition of the classic "Ashby and Wright" on Diseases of Children. While tuberculous bone disease in children interested Wright most—he was one of the first to treat spinal abscesses by evacuation without drainage—he covered the whole ground of surgical anatomy in a handbook published jointly with Mr. C. H. Preston in 1902. Soon after his succession to the full staff of the Royal Infirmary he had to give up his active connexion with Pendlebury, but as consulting surgeon ever retained his active interest in its welfare and progress. In 1900, after holding for some years lectureships in operative and practical surgery in the University of Manchester, he was appointed to the chair of systematic surgery vacant on the death in South Africa of Professor Tom Jones. This post he filled with distinction till 1911, when on retirement under the age rule his services were recognised by the University with the title of Emeritus. The transfer of the Royal Infirmary from its old home in Piccadilly to the new site in Oxford-road took place while Wright was senior surgeon, and he took a large share in the negotiations and in the planning of the new buildings. While teacher of surgery he examined at his old University of Oxford, and also at Birmingham and Liverpool, besides being an internal examiner at Manchester. He served for many years on the Council of the Royal College of Surgeons of England.

Professor Wright made for himself a well-earned reputation as a teacher of clinical surgery, and his ward classes were largely attended. He could not tolerate sham or attempts at concealment, for he was singularly out-spoken himself, expressing his opinions regardless of consequences. His lectures were no mere text-book transcriptions, but were founded on his own wide clinical experience, and he never tired of advising the student to read surgical classics, such as Hilton's "Rest and Pain." His interest in all that affected medical politics was great, and it was characteristic of his outlook that he was not always to be found in the camp of the majority. He took especial interest in the foundation of the National Medical Union and presided over it for some years. His interest in his students was shown in friendly talks at his own home over class examination papers, and by his long and at last successful efforts to found a senior medical students' hostel in Manchester. Lister House owed much to him, and many students now on the staff at Manchester or elsewhere look back gratefully to pleasant afternoons and evenings at his house in Oxford-road or at Bowdon and Holmes Chapel. As a colleague he was a firm friend, with generous and kindly instincts. No consultant in the North was so often invited to settle ethical disputes amongst his brethren, and he used to favour the institution of a course of lectures on medical ethics. He was, apart from professional life, an enthusiastic sportsman, and while still engaged in active practice it was his custom for many years to spend the week-ends at his cottage in Cheshire, where he took a great interest in gardening, and had abundant opportunities of indulging in his favourite pastimes, shooting and fishing.

Sir William Thorburn writes: "George Arthur Wright came to Manchester in 1880, and from the first impressed himself upon the profession as a man of exceptional ability and of great personal charm. I was a medical student when I came under Wright's influence, and can never forget his clear and lucid teaching, his patient sympathy, and his devotion to the interests of the medical school of which he was to become so great an ornament. Perhaps the happiest work of Wright's life was done at the Children's Hospital at Pendlebury. Himself childless, he was devoted to the young, and a true lover also of animals. With children he was a universal favourite, and the surgery of childhood was his main preoccupation. No doubt his painstaking and accurate observations in connexion with the surgery of the hip-joint have called for modifications with the progress of time, but he laid the basis of much of our present knowledge, while his work, written in conjunction with his intimate friend, Henry Ashby, upon Diseases of Children, will be a permanent monument. Wright took a most active interest in all matters of public importance in connexion with the profession. Of strongly conservative views, he was unbending in his advocacy of whatever he believed to be the right course, but he never failed to hold the esteem and even the affection of his most bitter opponents. His honesty of character and his loving and affectionate disposition endeared him to all. As a colleague the strongest impression which he gave was that of *reliability*; his surgical opinion was always sound and carefully reasoned; his clear and direct vision were unfailing. Whatsoever his hands found to do he did it with his might."

When the scheme of Territorial hospitals arose, Wright was selected in 1908 as first administrator of the 2nd Western General. This post he had already given up before the war, but his interest in military surgery never waned and he returned from retirement to take charge of a Red Cross auxiliary hospital at Worsley Hall, and later was appointed to command the surgical section of Queen Mary Hospital at Whalley, with his old rank of lieutenant-colonel. Retiring finally to Sidmouth in June of last year, he did not long survive to enjoy the fruits of leisure. His body was cremated at Golders Green. At a meeting of the board of management of the Manchester Royal Infirmary, on March 30th, a resolution was passed expressing appreciation of Mr. Wright's long and fruitful period of work at the infirmary, and sympathy for his widow.

ROYAL INSTITUTION OF GREAT BRITAIN.—Major G. W. C. Kaye will deliver the first of two lectures on Recent Advances in X Ray Work on April 13th, at 3 o'clock.

DONATIONS AND BEQUESTS.—The late Mr. Francis Wakefield Russell Skey, of Maida Vale, W., among other bequests left £2000 each to St. Bartholomew's Hospital and the Prince of Wales's Hospital Fund; £1000 to the Essex County Hospital, and ultimate residue of about £20,000 to St. Dunstan's Hostel for the Blind.—The late Dr. Cecil Rupert Chaworth Lyster, one of the pioneers in X ray investigation, has left £100 to the Middlesex Hospital Medical School to endow a prize for physics.

Medical News.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the Convocation held on March 27th the following degrees were conferred:—

Doctor of Medicine (Essay)—Frederick John Nattrass and Harry Reah.
Doctor of Medicine for Practitioners of 15 years' standing—Charles Edwards, David Fyfe, John Livingston, and Richard Galway Murray
Doctor of Hygiene—William Henry Rowell
Bachelor of Medicine and Bachelor of Surgery—Tom Hugh Ronald Anderson, Paige Canney Arnold, Neil Robertson Beattie, John Francis Carter Braine, Robson Christie Brown, John Hotherington, George Hurrell, and Carl Damien Newman
Bachelor of Medicine—Arthur Patterson
Bachelor of Surgery—James Dixon Johnson
Bachelor of Hygiene—Sidney Scott and Arthur Henry Towers
Diploma in Public Health—Sidney Scott and Arthur Henry Towers
Licence in Dental Surgery—James Leslie Liddell

UNIVERSITY OF LIVERPOOL: LIVERPOOL SCHOOL OF TROPICAL MEDICINE.—The Senate has awarded the Diploma in Tropical Medicine of the University of Liverpool to the following:—

W J W Anderson, M D Leeds, C E Cobb, L R C P Lond, M R C S, Enid M M Cobb, L R C P Lond, M R C S D D. Fernandes, L R C P & S Edin, L R F P S Glasg, P T J O Farrell, L R C P & S Irel, E A Renner, M B, Ch B Edin, and J C Vaughan, M B, Ch B Glasg

UNIVERSITY OF DUBLIN, SCHOOL OF PHYSIC, TRINITY COLLEGE.—At examinations held recently the following candidates were successful:—

FINAL MEDICAL EXAMINATION

Part I, Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene, Pathology—Eric Sealy Horgan (high marks), Eric Richard Murray (high marks), Leo Herzenberg (high marks), Hector Charles Chatterton Deane, Edith Florence Willock, Patrick Mary Joseph Bobbett, Constance McIlrath, Leo Vincent Clifford, Donald Victor Latham, Michael Raphael Coolican, Thomas Whelan Panter, and Rita Dillon-Leetch
Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene—Alfred Henry Norman Todd and Vera Gladys May Menary
Pathology—Doris Holland
Pathology, completing Examination—Francis Young Pratt, Robert Henry Joseph Mulhall Corbet, James Daly Leahy, Richard Wood Power, Robert Sturgeon Chapman, Alfred John Beckett, and John Mervyn Semple
Part II, Medicine—Philip Jabkovitz, Bernard Moshal, George Hall Davis, Henry Allman Lavelle, Adrian Johannes Louw Snyman, Salmon Louis Feldman and William Bernard Joseph Pemberton (equal), Joseph Ballantyne Maguire, William Theodore Micks, Athanas Blagoff, Arthur Isaac Steyn, Francis Healy and Daniel McElwee (equal), Samuel Reginald Hill, Johannes Marthinus Benjamin de Wet, Herbert Victor Exner, Richard Esmonde Murphy and John Farneworth Sheppard (equal), Elsie Anna Burns, and Johannes Philippus de Villiers
Surgery—Salmon Louis Feldman, Wonter de Vos Scholtz, George Hall Davis, William Burton Fox, Olive Baile and Frederick William Robertson (equal), Eileen Hilda Dowse and Joseph Hirschmann (equal), Janie Millar Cummins, William Frederick McConnell, Johannes Marthinus Benjamin de Wet, John Farneworth Sheppard, Daniel McElwee, Essie Stuart Smyth and John Richard Waugh
Midwifery—Henry Allman Lavelle (high marks), Bernard Moshal (high marks), Adrian Johannes Louw Snyman (high marks), George Hall Davis (high marks), Frederick Ziervogel Van der Merwe, Maurice Nurock, Johan Frederik Wicht, Herbert Victor Exner, Johannes Cornelis Coetzee, Eric William Swain Deale and Francis Victor Small (equal), Christopher John Laurence Brock, Johannes Marthinus Benjamin de Wet and William James Alexander Russell (equal), Moira Mary Brown, Doris Louisa Graham, Elsie Anna Burns, and Isaac Levy

DIPLOMA IN PUBLIC HEALTH

Part I, Bacteriology, Chemistry, Physics, and Meteorology—Cornelius Charles Boyle, Charles Joseph McCarthy, Patrick Rock, James Lyons, Thomas Declan Power, Matthew Joseph Graham, Percival Atkin Dormer, Charles Henry Comerford and John Francis Gaha and Charles Edward Pengelley (equal), Alfred Henry Price and Edwin Lawrance Sturdee (equal), William Benjamin Walker, and Mary Christina Sheppard
Part II, Sanitary Engineering, Sanitary Inspection and Report, Hygiene, Epidemiology, Vital Statistics, Public Health Law—Thomas Declan Power, Charles Joseph McCarthy, Edwin Lawrance Sturdee, James Lyons, William Benjamin Walker, Norman Parsons Jewell, George Francis Innes Harkness, Percival Atkin Dormer, Cornelius Charles Boyle, William Henry Sutcliffe, and George Oliver Fairtlough Alley

ROYAL MEDICAL BENEVOLENT FUND.—The annual meeting of the Fund was held on March 16th, with Sir Charters Symonds in the chair The financial report presented showed that donations and subscriptions exceeded by £196 those of the previous year, the total amount distributed being £2532. Attention is drawn in the report to the need of an additional £1000, since owing to the increased cost of living it is necessary to increase the amount of the grants. Up to the present only about 7 per cent of the medical profession have contributed to the Fund. The annuitants now number 178. The War Emergency Fund has distributed a total amount of £8540 Sir Thomas Barlow was elected president, Sir Charters Symonds honorary treasurer, and Dr. G Newton Pitt honorary secretary for the ensuing year. Donations and subscriptions may be sent to the honorary treasurer, at 11, Chandos street, Cavendish-square, London, W.1.

At the last meeting of the committee of the War Emergency Fund, Sir Alfred Pearce Gould in the chair, grants amounting to £800 were made to seven of the applicants. This Fund considers applications from demobilised R.A.M.C. officers, with a view of assisting them to re establish themselves in their practices.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—A Statistical Report Committee, consisting of Sir Arthur Stanley (chairman), Sir Cooper Perry, and Mr. Leonard L. Cohen, has been appointed to consider suggestions for the enlargement or improvement of the Fund's statistical report, and to make recommendations

HARVEIAN SOCIETY.—The next meeting of this society will be clinical, and will be held at the Maida Vale Hospital for Nervous Diseases on Thursday, April 15th, at 5 30 P.M.

LEICESTER MEDICAL SOCIETY.—A short course of post graduate study has been arranged to start on Tuesday, April 13th, continuing every Tuesday until May 11th. Lectures will be given by Dr. W. Langdon Brown on the Sympathetic Nervous System and the Ductless Glands, Glycosuria, and Disorders of the Digestive System.

FOOD EDUCATION SOCIETY.—A Conference on the Prevention of Diseases of the Teeth will be held at Manchester on May 13th-15th, 1920, under the auspices of the Food Education Society, Danes Inn House, 265, Strand, W.C.2, from whose secretary full particulars may be obtained.

THE FEDERATION OF MEDICAL AND ALLIED SOCIETIES.—At the monthly meeting of the Executive Council of the Federation held at 11, Chandos street, W, on March 30th, it was resolved to set up an "Advisory Council" composed of the representatives of all the corporate and individual representatives in order that the views of all the societies coöperating should be more readily available to the Executive Council. It was resolved to invite the British Medical Association to reopen the conferences between various medical bodies held in May, June, and July, 1919, with a view to securing closer coöperation. A number of medical men were elected individual associates of the Federation. Dr. A. Blackhall-Morison (North London Medical and Chirurgical Society), Dr. E H. M. Stancomb (Southampton Medical Parliamentary Committee), and Dr. G. B. Batten (Sydenham District Medical Society) were elected members of the Executive Council.

QUEEN CHARLOTTE'S HOSPITAL.—Sir Samuel Scott presided at the annual meeting of governors on March 30th. After referring to the loss sustained in the death of Lord Portman, President of the hospital for 30 years, he recorded the increasing demand on the services of the hospital, nearly 2000 patients having been treated during the year in the wards and a similar number attended in their own homes, while over 5000 patients had passed through the antenatal and child welfare departments. In consequence of the continued increase in prices there was a deficiency on the year's working of £2071 As a consequence, the committee was unable to proceed with the new out patient department and other urgently needed improvements. There had been a large increase in the number of medical practitioners, students, midwives, and nurses entering for training, some members of the Colonial and American medical and nursing services having taken out courses on demobilisation He appealed for increased support to enable the hospital to pay off a debt of £11,000 accumulated during the war, and for £100,000 estimated as required to make the hospital adequate to cope with the demands upon its assistance.

NORFOLK AND NORWICH EYE INFIRMARY.—This infirmary is the only hospital in the eastern counties entirely devoted to the treatment of eye diseases At the annual meeting of the subscribers, held recently, the chairman of the committee, Mr. E Knight, said he hoped that in the near future an ophthalmic block would be built in the grounds of the Norfolk and Norwich Hospital, and that, in his opinion, the Eye Infirmary would be in a much stronger position if amalgamated with the hospital. The medical report for 1919, signed by Mr. C. J. Muriel, Mr. Arthur Greene, and Mr. G. Maxted, the honorary surgeons to the institution, calls attention to the inadequacy of the number of beds, and consequent delay in treatment, patients having sometimes to wait months for admission. During the year 244 in patients were admitted, and 13 pensioners sent by the War Pensions Committees The average duration of each patient's stay in hospital was 14 days. There were 235 operations performed. In the out-patient department the total number of attendances was 4727, the number of new patients 1628, and of pensioners 96. The average attendance per day was 31, and the number of accidents 383. The number of pairs of spectacles prescribed was 610. This hospital, like most others, is in want of funds. A sum of £260, realised by a children's fancy dress ball at St. Andrew's Hall, Norwich, during the winter, and two concerts organised by friends of the institution helped to augment the funds, which are greatly in need of further help.

GREAT NORTHERN CENTRAL HOSPITAL.—H.M. Queen Alexandra will attend the matinée at the Palladium on May 24th to celebrate the jubilee of the Ladies' Association of the Great Northern Central Hospital, Holloway. An imposing list of patronesses and patrons has been secured.

EDINBURGH ROYAL INFIRMARY. — The special campaign organised to raise funds for the Royal Infirmary was opened in the City Chambers, Edinburgh, on March 30th. The Lord Provost, Sheriff Crole, and Sir Alfred Ewing, Principal of the University, spoke of the valuable work done by the institution, and of the important part it played in connexion with the nation, the city, and the great medical school of Edinburgh. Expenses had enormously increased; several departments were in urgent need of enlargement and additional equipment; the nursing staff needed to be augmented, and it was sought to reduce the hours for the nurses. In order to do this their numbers would have to be increased. The infirmary supplied a great need, and, moreover, the reputation of the Edinburgh Medical School was largely dependent upon the facilities for teaching in the wards of the infirmary. All these things were pointed out by the speakers. During the past year the directors have been compelled to reduce the deficit by the application of legacies received. The people who benefit most from the infirmary are the workers, some of whom make regular contributions. The sum required is £250,000 for renewals and extensions, and a further £50,000 for the annual upkeep.

ROYAL PORTSMOUTH HOSPITAL.—The report of this hospital for the year 1919 was presented to the subscribers at the annual meeting held in the Town Hall on March 26th. The military wards have been handed back and the hospital has returned to normal peace conditions. The total number of patients treated was 12,062—viz., in-patients 2397, out-patients and casualties 9665. The average cost per bed occupied was £115 2*s.* 4*d.*, and of each in-patient was £6 14*s.* 10*d.*, as compared with £3 16*s.* 6*d.* in 1913. The expenditure upon salaries of nurses, &c., also shows a large increase. The excess of expenditure over income, excluding legacies, amounted to £7386. The number of attendances was 19,847, as compared with 11,144 in 1918 and 8636 in 1917. The number of patients would probably have been greater had it not been for the inadequate accommodation. To meet the increasing demands for general treatment the Portsmouth Corporation have decided to erect temporary additions to the present building. The venereal diseases department has proved a success, and 949 new patients have attended, making a total of 2136 since the opening of the department in February, 1917. The Committee of Management has been reorganised and the working classes have been given a larger direct interest in the control of the institution. This new constitution will, it is hoped, increase the confidence of the public in the government of the hospital and be the commencement of a new era of prosperity.

ROYAL VICTORIA HOSPITAL, BELFAST.—At the annual meeting of the supporters of the Royal Victoria Hospital, held on March 31st, it was shown that the annual report presented more satisfactory features than any previous one except on the financial side. Each intern surgeon had performed about 300 major operations in the year, the total mortality for these operations being only 2·81 per cent. Of the operations 712 were abdominal, with a death-rate of only 5 per cent. A travelling X ray apparatus is being provided by the board of management, so that patients can be radiographed in their beds. The bacteriological department has been made more efficient, and a dental department has been inaugurated. No less than 265 students have enrolled their names. The year ended with a deficit of £5745, and it has been estimated that, owing to the rising prices, a sum of at least £7000 must be provided for the current year's income. It is realised that to secure an annual and certain income for the upkeep of the hospital reliance must be placed on those who get the greatest advantages therefrom—namely, the employers and the work-people. Both these sections of the community in Belfast have made enormous sums of money during the war and are still making good incomes, and for both the Royal Victoria Hospital is an admirable insurance against accidents and disease; they are therefore both asked to give far more generously to its funds.

Parliamentary Intelligence.

HOUSE OF COMMONS.

MONDAY, MARCH 29TH.

An Officer's Medical Appeal.

Mr. BOWERMAN asked the Parliamentary Secretary to the Pensions Ministry whether the claim to a pension by Mr. P. H. Young, late second lieutenant, The Buffs, might be reconsidered in view of the medical evidence presented by this officer to the effect that a contracted muscle in the leg, due to wounds, would never improve.—Sir J. CRAIG replied: This officer was awarded a gratuity under Article 8 of the Royal Warrant of August 1st, 1917, as being disabled to the extent of less than 20 per cent., but in view of the appeal which the honourable Member makes on his behalf arrangements are being made to have him re-examined by a medical appeal board.

Tool-grinders and Fibroid Phthisis.

Mr. WILLIAM THORNE asked the Secretary for the Home Department if he was aware of the death-rate in the tool-grinding and polishing industry; that a large percentage of the men suffered from phthisis; that the men in question were not scheduled under the Workmen's Compensation Act as a dangerous trade; and whether, in consequence of the death-rate and the amount of illness through this virulent disease, he could state if he could see his way clear to have an inquiry into the trade, or if he would have it scheduled as a dangerous trade.—Mr. SHORTT replied: The workers employed in certain sections of the metal-grinding trades do undoubtedly incur serious risk from the disease known as fibroid phthisis or silicosis, and a special inquiry into these trades is already in progress with a view to supplementing the regulations at present in force for the prevention of the disease, and to make a scheme or schemes of compensation under the special powers given for this purpose by the Workmen's Compensation (Silicosis) Act of 1918. The inquiry is a difficult one and has to cover a wide field, but it is being pressed forward as rapidly as possible.

TUESDAY, MARCH 30TH.

Treatment of War Nurses.

Mr. GRUNDY asked the Secretary for War whether his attention had been drawn to the public appeals being made, in connexion with the Nation's Fund for Nurses, for charity for nurses who gave their services to the country during the war; whether the treatment of these nurses had been such as to render appeals for charity necessary; whether he knew or would ascertain the identity of the voluntary aid detachment nurse Juliet, referred to in the public appeal as a nurse who went through the war and who now suffered from bad eyesight and shattered nerves and was in precarious circumstances; and whether, in order to remove doubts, he could make a statement as to the treatment accorded to nurses who served during the war.—Sir A. WILLIAMSON (Financial Secretary to the War Office) replied: Nurses temporarily employed by the War Office during the war have received pay and allowances on appropriate scales, and have been treated in case of disability on the same lines as members of the Queen Alexandra's Imperial Military Nursing Service. The War Office is not responsible for nurses employed by the British Red Cross Society or other organisations. If the nurse to whom the honourable Member refers was employed by the War Office, and he is not satisfied that she has received proper treatment, perhaps he will let me have further particulars.

Medical Officer's Return from Mesopotamia.

Major D. DAVIES asked the Secretary for War whether instructions had been given for the return from Mesopotamia of Captain Milton Jones, R.A.M.C., whose release had been applied for by the Montgomery Insurance Committee; and when Captain Milton Jones's return might be expected.—Sir A. WILLIAMSON (Financial Secretary to the War Office) replied: The General Officer Commanding in Mesopotamia has been informed by cable that Captain Milton Jones is urgently required, and this will be considered in assessing his claim for priority of release. In view of the fact that Captain Jones is 27 years of age and has served since November, 1917, it is not considered advisable to issue orders for his return which would give him priority over other officers of greater age and longer service who are similarly detained in Mesopotamia.

WEDNESDAY, MARCH 31ST.

Ex-Service Men in Public Asylums.

Major ENTWISTLE asked the Minister of Health if he would state how many discharged soldiers and sailors were at present in public asylums; and if it was intended to provide any other accommodation for these men.—Major BAIRD (Under Secretary for Home Affairs) replied: My right honourable friend has asked me to reply The number is about 4000 As regards the second part of the question, so far as I am aware, there is no intention to provide other accommodation for these men, and I am advised that there would be serious objections to treating these cases in special establishments The matter is discussed in the report of the Board of Control for 1917. There is also the important point that under the present arrangements it is possible in many cases to transfer to an asylum closer to his relatives, and a large number of applications for such transfers have been received.

Lieutenant Colonel MALONE. Are not many of these cases not really very serious, and likely to return to complete sanity if they were put into more suitable accommodation?—Major BAIRD I do not think that follows I think they are receiving the best possible treatment likely to lead to their recovery.

Grants in Aid for the Blind

Captain REDMOND asked the Chief Secretary to the Lord Lieutenant of Ireland whether he was aware that the Ministry of Health was now making grants in aid of services for the blind in Great Britain, and that their lordships of the Treasury had promised to ask Parliament to vote an interim grant of £12,000 for services carried on for the benefit of the blind in Ireland; and if he would state when the House would be asked to sanction this amount—Mr MACPHERSON replied The reply to the first part of the question is in the affirmative As regards the latter part, a Supplementary Estimate for the current financial year makes provision, amounting to £7000, for the payment of instalments of grants at a rate not exceeding 50 per cent of the estimated grants for the year.

Tuberculous Soldier in Barnstaple Workhouse

Captain TUDOR REES asked the Minister of Pensions whether he was aware that a discharged soldier suffering from tuberculosis had been in the Barnstaple Workhouse for five months, and that appeals had been made without success to the Pensions Ministry for his removal, and that the man was now in a serious condition; and whether he would take steps to have him removed for treatment to a military hospital or elsewhere—Sir L WORTHINGTON EVANS replied: In the time at my disposal I have not been able to ascertain the facts of the particular case, but as I explained recently in reply to a general question on this subject, when a man enters a Poor law institution for treatment of a war disability notification is at once sent to the Local War Pensions Committee, who take steps to remove him in order that he may be given the special treatment which his disability requires If my honourable and gallant friend will give me particulars of the case I will have immediate inquiry made and will inform him of the result

Captain T REES Is the right honourable gentleman aware that appeals have been made by the Local Pensions Committee in London without any effect?—Sir L WORTHINGTON EVANS My honourable friend has not given me an opportunity to make my inquiries, so that it is obvious that I do not know that If he will give me that opportunity I will see to it at once

Zymotic Diseases at Woodford

Mr R YOUNG asked the Minister of Health how many persons had suffered from zymotic diseases in the Woodford parish of Essex and the number of deaths monthly since April, 1919; and whether the main contributory cause was that in wet weather the sewage conduit pipe leading to the sewerage works of the Woodford Council overflowed into the adjoining ditches and that those ditches had not been properly cleared and cleansed—Dr. ADDISON replied The total number of notifications of zymotic and other infectious diseases in the parish since April 1st, 1919, is as follows Diphtheria, 48, scarlet fever, 38, measles and German measles 26, enteric fever, 1; puerperal fever, 1; malaria, 17, influenzal pneumonia, 20 The only deaths in the parish from zymotic diseases during the same period were five deaths from diphtheria I have no complete information as to the number of notifications and deaths for each month during that period As regards the last part of the question, I am advised that there is no ground for believing that the condition of the sewage conduit pipe referred to is a contributory cause of illness or death from zymotic disease.

Welsh Board of Health Appointments

Mr A T DAVIES asked the Minister of Health what were the important administrative appointments already made in connexion with the Welsh Board of Health, and how many of these, if any, had been given to women—Dr ADDISON replied The only important administrative appointments made in connexion with the Welsh Board of Health are the following: The chairman, the Housing Commissioner, and the Deputy Controller of Insurance have been appointed as members of the Board A medical officer has also been appointed temporarily to the Board The post of secretary has been filled, the secretary being ex-officio a member of the Board

Mr. DAVIES asked the Minister of Health if he had succeeded in finding a suitable woman member for the Board, and if not whether he would take the advice of well known women's organisations on the subject—Dr ADDISON replied I have not hitherto sought to appoint a woman as member of the Board of Health in Wales, because there is no woman member of the staff of the Ministry in Wales with appropriate responsibilities and experience

Influenza

Major ENTWISTLE asked the Minister of Health what steps had been taken, and what steps he proposed to take, with regard to the increase in the number of deaths as a result of influenza—Dr ADDISON replied In the reply which I gave on Feb 23rd to Lieutenant Colonel Raw is contained a complete statement of the steps which have been, and are being, taken for dealing with an epidemic of influenza should it occur. I am advised that the recent small increase in the number of deaths from influenza may be attributed partly to the normal rise which usually occurs at this season of the year, and possibly also to some deaths from pneumonia being ascribed to influenza as a contributory cause It is noteworthy that the number of deaths from pneumonia has remained practically constant each week since the end of January last

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE 1, Wimpole-street W

MEETINGS OF SECTIONS

Thursday, April 15th

DERMATOLOGY (Hon Secretary—Henry MacCormac) at 5 P M

Cases (4 30 P M)

Dr Barber Cases of Lupus Erythematosus treated by Autogenous Streptococcal Vaccine

Other cases will be shown

Friday, April 16th

CLINICAL (Hon Secretaries—T P Legg, S A K Wilson) at 5 30 P M

Cases (at 5 P M)

ELECTRO THERAPEUTICS (Hon Secretaries—Walter J Turrell, Stanley Melville) at 8 30 P M

Mackenzie Davidson Memorial Lecture

Professor Sir Ernest Rutherford Development of Radiology

SOCIETY FOR THE STUDY OF INEBRIETY, in the Rooms of the Medical Society of London, 11, Chandos street, Cavendish square, W

TUESDAY, April 13th—4 P M, Annual Meeting Election of President Council, and Officers for the ensuing Session Discussion on Analytical Psychology in Alcoholism opened by Dr M Nicoll

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST GRADUATE COLLEGE, West London Hospital, Hammersmith, W

THURSDAY, April 15th—4.30 P M, Dr Langley Mitral Incompetence and Ability to Work (At Ancoats Hospital)

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Bower, E. D., M.D. Durh., F.R.C.S. Edin. has been appointed Consulting Ophthalmic Surgeon to the Gloucestershire Royal Infirmary.

Hadfield, G., M.D. Lond., Pathologist to the Bristol General Hospital.

Howell, B. W., F.R.C.S., Assistant Surgeon to the Queen's Hospital for Children, Hackney-road.

Lakin, C. E., M.D., F.R.C.P., Physician to the Middlesex Hospital.

London Hospital Medical College: Holland, E. L., M.D. Lond., and Luker, S. G., M.B. Cantab., Joint Lecturers on Midwifery; Culpin, M., M.B., B.S., Lond., Lecturer on Psycho-Neuroses.

Certifying Surgeons under the Factory and Workshop Acts: Hamilton, E. S. B., M.B., Ch.B. Edin (Salford and Stretford); Acheson, D. R., M.B., Ch.B. Belf. (Berkeley); Brocket, J., M.B., Ch.B. Edin. (Stourport); Upward, H. A., M.B., B.C. Cantab. (Romford); Thompson, W. R., L.R.C.P. & S. Edin. (Shelf); Meade, J., L.R.C.P. & S. Edin., L.F.P.S., Glas. (Bruff); Fawcett, R. F. M., L.R.C.P. & S. Edin., L.F.P.S. Glas. (Toddington); Thompson, W. E. (Woburn Sands); Smith, H. G. (Shrewsbury); Scott, A., M.B., C.M. Glas. (Uphall).

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne District Infirmary.—Two Asst. H.S.'s. £200.

Barnsley, Beckett Hospital.—Jun. H.S. £180.

Barrow-in-Furness, North Lonsdale Hospital.—Second Res. H.S. £225.

Belfast Mater Infirmorum Hospital.—Hon. P.

Birkenhead Borough Hospital.—Sen. and Jun. H.S.'s. £200 and £170.

Birmingham and Midland Ear and Throat Hospital.—Asst. S.

Birmingham City Fever Hospital Service.—Asst. M.O. £350.

Birmingham City Hospital, Little Bromwich.—Med. Supt. £700.

Birmingham City Education Committee.—Aural S. £130.

Brighton, Royal Sussex County Hospital.—Hon. Asst. P.

Burnley County Borough.—Asst. M.O. £550.

Burnley, Victoria Hospital—H.S. £250.

Cardiff, Glan Ely Hospital.—Asst. Res. M.O. £400.

Cardiff, University College of South Wales and Monmouthshire.—Professor of Physiology. £900.

Carshalton, Surrey, Queen Mary's Hospital for Children.—Senior Asst. and Junior Asst. M.O.'s. £645 5*s.* and £515 6*s.* respectively.

Chingford Hospital for Infectious Diseases.—Res. M.O. £325.

Derby, Derbyshire Royal Infirmary.—Oph. H.S. £200.

Dorset County Council.—Asst. County M.O. £500.

Eastbourne Eye Infirmary.—Hon. Oph. S.

Glossop Dale Rural District Council.—Joint M.O.H. £600.

Great Northern Central Hospital, Holloway, N.—H.S. £150.

Hospital for Consumption and Diseases of the Chest, Brompton.—H.P. 30 guineas.

Huddersfield Royal Infirmary.—Asst. H.S. £150.

Hull City Education Committee.—Asst. Sch. M.O. £500.

Hull Royal Infirmary.—Senr. H.S. £200. Also Cas. H.S. £150. Also Asst. H.S. £250.

King's College Hospital, Denmark Hill, S.E.—Med. Out-patients' O. and Surg. Out-patients' O. £250.

Leeds University.—Demonstrator in Exp. Phys. £250.

Leeds Public Dispensary.—Res. M.O. £200.

Leicester Royal Infirmary.—Hon. Asst. P.

Liverpool City and Port.—Asst. Port M.O. £650.

Liverpool, David Lewis Northern Hospital.—Two H.P.'s and One H.S. £150 each.

London Hospital, Whitechapel, E.—Surgical Registrar. £365. Also Medical Registrar. £365.

London Temperance Hospital, Hampstead-road, N.W.—Cas. O. £120.

Loughborough and District General Hospital and Dispensary.—Res. H.S. £200.

Macclesfield, Cheshire County Asylum, Parkside.—Asst. M.O. £350.

Maidstone, Kent County Ophthalmic Hospital.—H.S. £250.

Manchester, Ancoats Hospital.—H.S. £100. Also Res. S.O. £200.

Manchester County Asylum, Prestwich.—Asst. M.O. £450.

Manchester Royal Eye Hospital.—Jun. H.S. £120.

Manchester Royal Infirmary.—Second H.S. to Special Dept. £25 first six months and £50 second.

Manchester, St. Mary's Hospitals for Women and Children.—Hon. Asst. P.

Margate, Princess Mary's Hospital for Children, Cliftonville.—Junior Asst. M.O. £579 14*s.*

Metropolitan Asylums Board.—Junr. Asst. M.O.'s in Mental Hosp. Service. £422.

Middlesbrough, North Riding Infirmary.—H.S. £200.

Mothers Hospital, 153-163, Lower Clapton-road, Hackney, E.—Res. M.O.

National Hospital for Diseases of the Heart, Westmoreland-street, W.—Hon. Asst. P.

Newark Hospital and Dispensary.—Res. H.S. £200.

Newcastle-upon-Tyne, Royal Victoria Infirmary.—Two Hon. Asst. S.'s, two Hon. Assts., and Hon. Surg. Registrar. Also H.P.'s, H.S.'s, and two Accident-room H.S.'s. £50 each, except H.S. to Out-patient Dressing Dept., which is £100. Also Refractionist. £100.

Norwich, Norfolk and Norwich Hospital.—Cas. O. £200.

Paddington Green Children's Hospital, London, W.—S. and P.'s. Also H.P. and H.S. £150 each.

Poplar Hospital for Accidents, Poplar, E.—Asst. Res. S. £120.

Portsmouth County Borough.—Asst. Tuberc. O. £500.

Queen Mary's Hospital for East End, Stratford, E.—H.P.

Reading, Royal Berks Hospital.—Senr. Res. M.O. £350.

Roll of Honour Hospital for Children, 688, Harrow-road, W.—Hon. Asst. P. and H.S. £40.

Royal College of Surgeons of England.—Examiners.

Royal Free Hospital, Gray's Inn-road, W.C.—Clin. Assts.

Salford Royal Hospital.—H.S. £150.

Sheffield Royal Infirmary.—Two H.S's, one Ear, Nose, and Throat H.S. £150.

Shoreditch Hospital, 201, Hoxton-street.—Res. Asst. M.O. £300.

South London Hospital for Women, South Side, Clapham Common, S.W.—Female H.S. £100.

Stamford, Rutland, and General Infirmary, Stamford.—H.S. £200.

Stoke-on-Trent, North Staffordshire Infirmary.—H.S. £200.

Straits Settlements and Federated Malay States.—Thirty-three M.O.'s. $440 per month.

Surrey, Royal Hospital, Richmond.—H.S. £150.

Sutton, Surrey, The Downs Sanatorium.—Senior Asst. M.O. £645 5*s.*

Swansea General and Eye Hospital.—Jun. H.S. £200. Also H.S.

Ventnor, Isle of Wight, Royal National Hospital for Consumption and Diseases of the Chest.—Asst. Res. M.O. £300.

Wakefield Clayton Hospital.—Junr. H.S. £200.

West London Hospital, Hammersmith, W.—Asst. Anæsth.

West Riding County Council.—Sch. Med. Inspec. £500.

Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £300. Also Deputy Supt. £450.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Melksham and at Youlgreave.

Births, Marriages, and Deaths.

BIRTHS.

Aitken.—On March 28th, at Park-street, W., the wife of D. McCrae Aitken, F.R.C.S., of a son.

Anderson.—On April 5th, at "Remony," Chislehurst, the wife of C. E. Anderson, M.R.C.S., of a son.

Burke.—On March 29th, at Central Nursing Home, Dundee, to the wife of E. T. Burke, D.S.O., M.B., Ch.B.—a son.

Garland Collins.—On March 31st, at Carlton Lodge, Snaresbrook, Essex, the wife of F. Garland Collins, Major (late R.A.M.C.), M.R.C.S., L.R.C.P. Lond., D.P.H., of a son.

Jones.—On March 28th, at Coleford House, Coleford, near Bath, Somerset, the wife of Philip T. Jones, M.R.C.S., L.R.C.P., of a daughter.

Moberly.—On March 28th, at Chudleigh, Ewell-road, Surbiton, Surrey, the wife of Alan V. Moberly, M.R.C.S., L.R.C.P., of a daughter.

Nattrass.—On March 31st, at 11, Archbold-terrace, Jesmond, Newcastle-upon-Tyne, the wife of F. J. Nattrass, M.D., of a son.

Peachell.—On April 3rd, at Herrison, Dorchester, the wife of Dr. G. E. Peachell, of a son.

Riddick.—On March 29th, at Sialkot, Punjab, India, the wife of Lieutenant-Colonel G. B. Riddick, R.A.M.C., of a son.

Smith.—On April 3rd, at 75, Broad-street, Barry, Glam., the wife of Mr. R. Eccles-Smith, O.B.E., M.B., F.R.C.S. Edin., of a son.

Tirard.—On March 31st, at Uttoxeter New-road, Derby, the wife of N. S. Tirard, M.B., of a son.

Trotter.—On April 2nd, at Claremont-terrace, Glasgow, W., Dr. Margaret Trotter, wife of Dr. G. Clark Trotter, of a daughter.

MARRIAGES.

Ritchie—Chalmers—On April 3rd, at Mabelbank, Broughty Ferry, W., Douglas David Ritchie, M.D., to Florence Margaret, daughter of Mr. and Mrs. Wm. Chalmers.

Robey—Cecil.—On March 31st, at St. Jude's Church, Southsea, Harry Webb Robey, L.D.S. Eng., to Mabel, third daughter of Mr. and Mrs. C. W. Cecil, of Southsea.

DEATHS.

Roper.—On April 3rd, at "Colby," Lewisham-hill, S.E., Dr. Arthur Roper, in his 82nd year.

Scattergood.—On March 29th, at Highfield House, Menston-in-Wharfedale, Oliver Scattergood, M.A., M.B Oxon., D.P.H. Cantab., M.R.C.S., in his 64th year.

Wills.—On March 21st, at Farnsfield, Notts, Charles Wills, M.R.C.S., L.S.A., aged 76.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

BOOKS, ETC., RECEIVED.

Notes, Short Comments, and Answers to Correspondents.

COLONIAL HEALTH REPORTS

Jamaica.

IN a report by Mr Robert Johnstone, acting Colonial Secretary, on the Blue book for 1918-19, the latest estimate of the population is given as 895,578 The birth rate in the year ended Dec 31st, 1918, was 34 1 and the death-rate 33 per 1000 Of the births registered 68 6 per 100 were illegitimate, as compared with 67 7 in the previous year, which was the highest island rate recorded since the introduction of compulsory registration in 1878.

During the last quarter of 1918 influenza and pneumonia visited Jamaica and spread swiftly, the epidemic claiming a heavy toll in every parish, with the exception of Port Royal It reached the greatest intensity about the middle of the quarter and then began gradually to subside 5002 deaths were registered as having been caused by influenza and 547 from pneumonia, but it is probable that a larger number of deaths actually occurred from these causes as a considerable proportion of the deaths registered in the island are not medically certified, and a large number of those that occurred during the prevalence of the epidemic were registered as having been caused merely by fever and cold Of the deaths caused by the epidemic 2702 were of persons of the ages of 20 to 45 years and 1150 of children under 5 years of age Yaws is still very prevalent throughout the island Venereal diseases are also extensively prevalent, and a new law has been passed providing for their compulsory treatment 2797 cases of malaria were admitted to the hospitals The number of cases reported during the year as "vomiting sickness' was 257, of which 242 were found to be instances of ackee poisoning In the other 15 cases the true causes of death were found by the Government bacteriologist to be as follows, viz cerebral malaria, 8 gastritis, 2 malaria and ackee, 1, ptomaine poisoning, 1, fish poisoning, 1, nephritis, 1, convulsions, 1

The total number of cases of all kinds admitted to public general hospitals during the year under review was 21,100 and amongst these there were 1165 deaths In addition, 3800 indoor and 16 106 outdoor patients were treated in the Kingston Hospital The number who attended the evening clinics in connexion with the treatment of cases of venereal disease was 2731, and the number of attendances was 9909 17,153 prescriptions were made up and 1598 intravenous injections were administered There were 113 patients in the Lepers Home on March 31st, 1918, and 20 were admitted during the year, while in the same period 1 absconded and 16 died

Grenada.

The estimated population at Dec 31st, 1918, was 73,881. The birth rate for the year was 34 66 and the death rate 17 08 per 1000 The mortality among children under 2 years was 38 4 per cent of the total of all deaths

The public health of the colony was reported by the colonial surgeon to be on the whole satisfactory The year was marked by the adoption of vigorous measures for the eradication of the loathsome diseases of syphilis and yaws It is stated in connexion with the treatment of venereal disease by injections of novarsenobillon that patients submitted willingly and latterly came forward voluntarily asking for injections The cases of venereal disease and syphilis treated amounted to 1579 of which 220 were discharged as cured The kindred complaint of yaws was also attacked by an intensive treatment with novarsenobillon ' It is said the disease in its worst forms succumbs in a short time to the effects of this drug The results are reported to be so encouraging as to hold out every hope that in a comparatively short period the disease will practically cease to exist in Grenada

The acting Colonial Secretary (Mr E D Laborde) adds in his review of the Blue book for 1918 19 'The colony can be described as an extremely healthy one for Europeans as well as for those born and bred in these parts The climate is mild, and in the dry season is salubrious and pleasant This period usually lasts from January to the end of May when the rains commence The latter part of the year is sometimes damp and as a rule, hot Daylight never exceeds 13 hours, and there is not more than an hour's difference between the longest and the shortest day The island is south of the hurricane zone and has been, fortunately, free from any cataclysm or seismic disturbance The last earthquake of any severity occurred in 1888 The temperature in the shade varied in 1918 from 69° to 90° F The rainfall was 81 40 inches, 3 77 more than the average in the three preceding years

LUNATIC ASYLUMS IN BENGAL, 1918

THE average population of the lunatic asylums in Bengal during 1918 was 1079, the admissions and readmissions numbering 334, an increase of 50 over those of the previous year The daily sick averaged 87 4 per 1000, and the deaths numbered 104, or 9 63 per cent, an increase over the ratio for 1917, which was 7 91, 29 of these deaths occurred amongst the new admissions, mostly attributable to their miserable state of health on arrival at the asylums The discharges numbered 319, of whom 151 (or 13 99 per cent of the total strength) were cured, 28 improved, 97 transferred, and 1 escaped No details are given as to the health of the asylum inmates, though it is stated that the year was particularly unhealthy. There were 104 deaths (96 3 per 1000), compared with 79 1 per 1000 in the previous year; tuberculosis accounted for 35 Influenza affected both the Berhampore and Dacca Asylums, where there were respectively 45 and 46 cases, but with only 2 deaths in the former and none in the latter asylum Colonel J. K. Close, I M.S, states that a new hospital is required at the Berhampore Asylum, the building at present used being a very old barrack, quite unsuitable for a hospital.

SANITATION IN INDIAN FACTORIES.

FROM the report on the working of the Indian Factories Act in Bengal, Bihar and Orissa, and Assam for 1918 we learn that water supply and ventilation are generally satisfactory and the sanitary arrangements fairly adequate. The septic tank system is in process of welcome installation, and there will soon be very few of the large textile factories in which the old insanitary hand service is retained Good filtered water supplies are generally provided Patterson gravity filters have been installed at a cost of Rs 125,000, supplying 20,000 gallons per hour to the Kelvin and Empire Jute Mills, the adjoining coolie lines and bazars, and thereby benefiting some 20 000 people; a similar installation, with a capacity of 12,000 gallons per hour, has been completed for the Kinnison Mills at a cost of Rs 50,000 The housing and general welfare of the factory operatives is receiving increased attention, and considerable sums have already been expended on improvements in the native villages, or *bustees*; the need for this is urgent At a recent inspection of coolie lines attached to a jute mill it was found that on an average ten persons were living in each room having an area of 10 × 14 ft The influenza visitation rapidly spread among the mill operatives around Calcutta, but was fortunately of short duration, "due largely to the special measures taken by mill managers to suppress the epidemic " Medicines and medical attendance were given freely An effective campaign against hookworm disease has been initiated by the Governor of the Province, with the coöperation of all the leading industries, and the jute mill companies have undertaken to provide 2000 rupees annually towards research work in connexion with the tropical diseases that interfere with the regular working of the labour force in factories

Mr. R P Adams, O.B E, Chief Inspector, who presents this report, states that during the last three years of the war industrial development has made considerable progress in these provinces, notwithstanding the difficulties in obtaining structural material and machinery from England and America Some new industries were started and others greatly expanded to meet the conditions caused by the war. The stimulus arising from these conditions has caused home manufacturers to consider the advisability of opening factories in India connected with their home concerns, and a big development may be expected in this direction

HEALTH OF BOMBAY JAILS, 1918

THE chief causes of sickness and death in the jails of Bombay Presidency during 1918 were influenza and its resulting pneumonia For the total jail population (average daily number of prisoners) of 12 095 the death ratio was 58 5 per 1000, as compared with 18 7 per 1000 in 1917 but if the influenza ratio of 36 per 1000 be deducted, the remaining ratio of 22 5 is but slightly in excess of that for the preceding year The general death rate for the population of Bombay Presidency is stated to have been 88 05 in 1918, compared with 40 76 in 1917 Several prisons were overcrowded throughout the year, relief being afforded by the use of tents, verandahs, and worksheds, or by transfers to other prisons Improvements were made in the dietaries, and warm clothing issued when considered necessary Not a single case of cholera occurred, and only 4 cases of plague, dysentery caused 307 admissions to hospital, a ratio of 31 8 per 1000 (with 10 deaths), compared with 418 admissions (44 6 per 1000) and 11 deaths in 1917. There were 184 2 admissions and 0 7 deaths per 1000 from malarial fevers, compared with 186 3 and 0 9 in 1917 Pulmonary tubercle showed an increased number of admissions (63, compared with 48 in 1917), but the deaths were 19 only, compared with 24 It is stated that at least 38 of these cases of tubercle contracted the disease outside the jail. At the "*Borstal*" juvenile jail, Dharwar, the boys are taught carpentering and other trades They take a pride in their gymnastics and drill and have started cricket

Colonel H. E Banatwala, C S I, I M S (retired), who presents the report, states that out of a total of 20,183 prisoners discharged from the Bombay jails during the year 55 3 per cent gained weight, 21 2 per cent lost weight, and 21 6 per cent remained stationary

BRITISH OPHTHALMIC HOSPITAL, JERUSALEM.

THE work of this hospital is increasingly heavy and the administration is urging the Order of St John to extend its activities in combating the ravages of eye disease in the Holy Land Captain Charles R B. Eyre, R A M C, has been appointed assistant surgeon to this hospital

CHLOROFORM BY THE OPEN METHOD.

A CORRESPONDENT, who in 1902 was advocating the open method of chloroform administration, thinks that it is time for us to confess that this is "universally accepted as the best mode." In a further communication he adds that "an editorial comment made 17 years ago has been proved to be utterly fallacious." Follows the quotation "*Audi alteram partem.*" In 1902 we were comparing this method with more accurate procedures to the detriment of the former, and the premiss on which we are asked to plead guilty of having been unintelligent in years gone by—quite an easy thing to apologise for—is unsound. It is not universally accepted that what is called the "open" method is the best. By the open method our correspondent means, we presume, that which is conducted by means of a drop-bottle and a Skinner's or similar mask. Now we believe that fewer anæsthetists to-day employ this method in preference to giving chloroform from a Junker's or Shipway's or Vernon Harcourt's apparatus than was the case in 1902. Moreover, when experts employ the open method they do so with confidence because of the knowledge gained from the employment of these percentage-dose machines. Further, there is scarcely one of them but would recommend the machine rather than the drop-bottle for general use by the student or the comparatively inexperienced administrator. Actually, the practice of to-day tends to eliminate chloroform more and more, particularly in the induction of anæsthesia. We believe that our views of 1902 are upheld by the practice of 1920.

GERMAN MEDICAL PRACTICE IN THE ARGENTINE.

IN the *Wien. klin. Wochenschr.* for March 11th Dr. J. Brinkmann, director of the German Hospital at Buenos Aires, seeks to stem the tide of German and Austrian emigration to South America in search of medical practice. There are, he says, at most 60,000 German-speaking people in Buenos Aires and its environs, many of whom prefer to call in Argentine doctors, whose seven-year training is, in many respects, he holds, better than that obtained in Germany and Austria. In the larger towns there are already a sufficiency of German doctors, and in country districts to gain a living is hard and precarious. The conditions in other South American republics are, he concludes, even less favourable. For many years past no foreigner has been able to obtain a practice in Bolivia, Paraguay, Chili, or Uruguay.

AEROPLANE TRAVEL.

LONDON to Brussels in 2½ hours; London to Paris in 3 hours. This announcement should make the eyes open wide of old travellers. The price is 15 guineas per passenger. Other regular routes are from Liverpool to London, and Southampton and Plymouth to London. The Central Aircraft Company, Ltd., of 179, High-road, Kilburn, N.W., invite intending passengers to telephone their requirements to Kilburn or to their aerodrome at Northolt, Middlesex, which is within a few minutes' walk of Northolt Junction, reached from Paddington or Marylebone Stations, or from Ruislip Station, reached from Baker Street Station. The cheapest flight is over Harrow for £1 2*s.* 6*d.*, and over the West-End and City for £2 3*s.* 6*d.* There is also a circuit of London for £6 10*s.* and a tour round London for £17 10*s.*, and a flight up the Thames Valley for £12 10*s.* Flights around Kent cost £25; around South Wales, £40; over several cathedral cities, £30; and £10 per hour is charged to follow racing in the Solent. More ambitious are the tour of the American front in four days for £120 and of the Belgian battlefields in three days for £60.

MALARIA IN CILICIA.

THE recent Armenian massacres in Cilicia, and especially at Marasch, are of special medical interest, as they have occurred in a region in which there is a peculiarly virulent malaria, which attacked the German troops in 1916 most severely. The story, recounted in the *Archiv für Schiffs- und Tropen-Hygiene* for December by Dr. Viktor Schilling, reminds us of the experiences of our own troops in Salonica. Cilicia is a mountainous province, with the two great mountain ranges, the Taurus to the north-west, the Amanus to the south-east, each with a direction through the country from the north-east to the south-west. Between them lies a high plateau, dry and scorchingly hot in summer, and becoming a marsh in winter. In summer the rivers disappear into small bush-covered streams, often merely a string of sheltered pools giving anopheles mosquitoes the best breeding-grounds possible. The high-lying valleys are no health resorts, but, being hot and swampy, are themselves full of mosquitoes infected by the malaria-ridden inhabitants, and are more dangerous to travellers than even the plains below. Dr. Schilling is of opinion that every one of the inhabitants has had malaria. German troops suffered severely after a 10 to 14 days' incubation, with severe pyrexia, vomiting, and diarrhœa, diagnosed sometimes as cholera, typhus, typhoid, or dysentery. Cases died of coma in four days; other cases were overcome and had no pyrexia. Intravenous quinine alone did good. Cases of blackwater fever were heard of. The disease was so deadly and so resistant to treatment that it was supposed the quinine was in fault, but the suspicion was undeserved. Mosquito nets and antimalarial measures other than quinine administration (15 gr. twice a week) could not be undertaken. Dr. Schilling thinks prophylactic quinine did diminish the attacks, lessened the mortality, delayed relapses, and enabled those who passed quickly through the danger area to recover more quickly from their attacks, but it was less successful than usual, because the infections were so numerous. The malaria was of very virulent type and unusually resistant to quinine; this applies to both benign and malignant tertian. Dr. Schilling found six rings in one red blood corpuscle. Cases which had no quinine prophylaxis were just as obstinate as the others. Near Aleppo of 46,000 blood examinations 11,000 showed malarial parasites, and mixed infections were particularly common. Culex and stegomyia were common in Aleppo, but anopheles were not found.

SWISS MEDICAL STUDENTS.

DURING the winter session 1919–20 a total of 1817 students (1581 men and 236 women) attended courses in the medical faculties of the five Swiss universities. Of this total 532 (424 men and 108 women) were foreigners. The attendance was distributed between the universities thus: Basle, 265; Berne, 388; Geneva, 408 (including 66 dental students); Lausanne, 270; Zurich, 486 (excluding 117 dental students).

THE late Ernst Haeckel's house in Jena is being rebuilt as a memorial institute for embryological research.

Milroy Lectures

ON

THE HIGHER FUNGI IN RELATION TO HUMAN PATHOLOGY

Delivered before the Royal College of Physicians of London

By ALDO CASTELLANI, C M G , M D ,
M R C P. LOND ,
PHYSICIAN TO THE TROPICAL HOSPITAL (MINISTRY OF PENSIONS)
LECTURER AT THE LONDON SCHOOL OF TROPICAL MEDICINE

LECTURE I.

Delivered on Feb 26th 1920

MR PRESIDENT, CENSORS AND FELLOWS OF THE COLLEGE,—I beg, first of all, to express to you my deep appreciation of the honour I have received in being asked to deliver the Milroy lectures for this year It is an honour I shall always very greatly value

As subject of my three lectures I have taken the Higher Fungi in Relation to Human Pathology The study of bacteria or lower fungi is so engrossing and has given results of such magnitude that there has been perhaps a tendency hitherto to overlook the importance, from a medical point of view, of vegetal organisms higher than bacteria There is little doubt, however, in my humble opinion, that further investigation will tend to increase the importance of these organisms in the same manner that the great medical importance of animal parasites higher than protozoa has already been recognised

In the first lecture I propose touching briefly on the subject of fungi in general, on their morphological characters and classification, and on their biological properties In the second and third lectures I propose studying them in relation to human disease, discussing briefly and giving a description of some of the less known affections of mycological origin in the investigation of which I happen to have taken a part

HISTORICAL

Mycology, the branch of botany which deals with the higher fungi may be said to have begun in the days of Charles II , when Hook constructed a magnifying lens and with it examined the yellow spots so often found on the leaves of the Damascus rose He saw that these spots were caused by certain filamentous fungi, of which he gave a detailed description, and left remarkably good drawings He believed, like many other observers after him, that fungi arose from spontaneous generation, especially in decaying matter

About the end of the same century (1686) Malpighi in his writings several times referred to parasitic fungi, especially to fungi of the type Mucedo In 1753 Linnæus, in his famous book "De Species Plantarum,' collected all that was known at the time on the subject, and named a large number of species After Linnæus many botanists carried out investigations on fungi it suffices to mention the names of Persoon, Link, Kutzing It is interesting to note, however that fungi parasitic of man did not, apparently, attract attention until the beginning of the last century The first fungus of importance found in man was the thrush fungus, by Langenbeck, in 1839 This author discovered the fungus while examining microscopically the white patches of thrush he found at the autopsy of a case of typhoid in the oral mucosa, the pharynx, and the whole of the intestine He believed at first that the fungus was the cause, not only of the white patches, but of the typhoid infection from which the patient had died

Berg, in 1842, gave a good description of the organism, and in 1843 Charles Robin made a complete investigation of it and called it *Oidium Albicans*, Charles Robin Robin wrote also a book on mycology, which has remained classic "Histoire Naturelle des Vegetaux Parasites qui croissent sur l'Homme et sur les Animaux Vivants" (J B Bailliere, Paris, 1853) It took a long time, however, for the idea that thrush was a mycological affection to be generally accepted Even many years after Charles Robin s classic work, numbers of physicians did not believe in it In the most popular text book of pathology of the "fifties" and "sixties" of last century, one reads that the thrush patches are the result of a morbid secretion of the oral mucosa, and the author adds, "a mycologist, however, has brought forward the peculiar idea that such patches are composed of a mass of vegetable organisms '

In the same year in which the thrush fungus was found (1839), Schoenlein discovered the fungus causing favus this organism a little later was further investigated by Lebert, who called it *Oidium Schoenleini*, and subsequently by Remack, who named it *Achorion Schoenleini*

In 1844 Gruby described the fungi found in ringworm, *and made a distinction between ringworm due to* a large spore fungus and ringworm due to a small spore fungus, a distinction which was ridiculed at the time and completely forgotten later, until many years after Sabouraud made the same distinction, and very *honourably called attention to Gruby s forgotten work*

In 1846 Eichstedt discovered the fungus of pityriasis versicolor Interest in the study of the higher microfungi continued to be great until the "seventies and "eighties of last century, when the epoch making discoveries of Pasteur and Koch brought bacteriology to the front, and mycology was relegated to the background *Interest in mycology slightly revived in the* last years of the century, this being principally due to the work of Sabouraud, and during the last 20 years, slowly but surely, this branch of knowledge has grown in importance

GENERAL REMARKS AND CLASSIFICATION

As well known, the *Regnum Vegetable*, or *Vegetal Kingdom*, is usually divided into four large groups, or *phyla* the Thallophyta, the Bryophyta, the Pteridophyta, and the Phanerogamæ, or Flowering Plants The Thallophyta may be defined as being vegetal organisms with a cellular structure, which is usually little differentiated, and reproducing *either asexually by division and by spore formation*, or sexually, *after conjugation*, by oospores These organisms may be separated into two classes —

1 Those with Chromatophores and chlorophyll—*Algæ*, Roth, 1797

2 Without Chromatophores or chlorophyll—*Fungaceæ*, Linnæus, 1737.

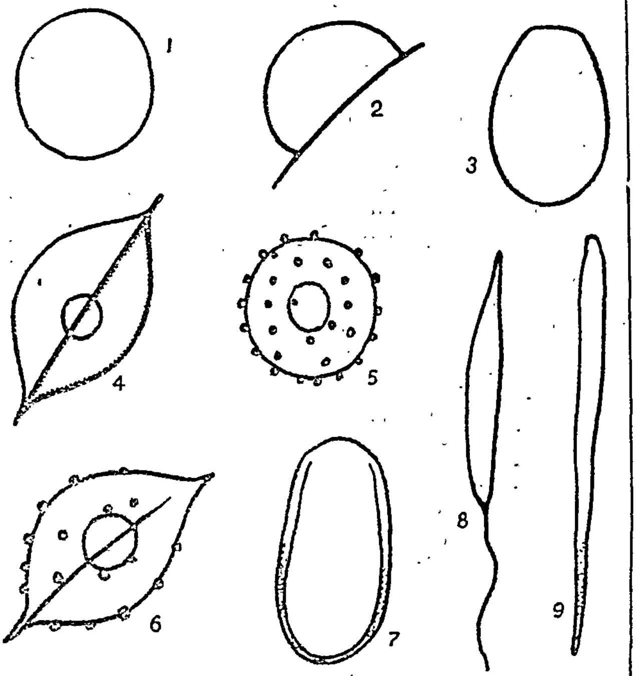
The Algæ are generally subdivided into the *Cyanophyceæ* (Blue Green Algæ) the *Chlorophyceæ* (Green Algæ), and the *Schizomycetaceæ* (bacteria *sensu lato*, or lower fungi) It must be noted, however, that the *Schizomycetaceæ*, or unicellular fungi, or lower fungi, or bacteria, are without chlorophyll and generally without chromatophores, and *it is therefore doubtful* whether it is correct to classify them with the Algæ, as is usually done They are believed, however, to have derived from the Cyanophyceæ, or Blue Green Algæ They may be defined as Thallophyta without chlorophyll starch or chromatophores, and with a vegetative body, which is usually composed of a mass of filaments, or "mycelium *The mycelial filaments or threads* are also known as *hyphæ*, and may be of very different shape, length, and breadth, they may be straight, variously bent, septate or non septate These organisms being unprovided with chlorophyll cannot make use for their nutrition *of the carbon dioxide of the air they derive their carbonaceous food material* from complex organic matter, often decaying matter Fungi may be *saprophytic* or *parasitic*, the same fungus may at times be a saprophyte at other times a true parasite

Reproduction.

The seeds of the higher plants may be said to be represented in the fungi by the roundish or oval bodies known by the generic term spores, of which there are a number of types, some sexual, some asexual (see Figs. 1, 2, 3). The principal ones are the following:—

1. *Gonidia* (endospores, spores *sensu stricto*).—These take origin inside a special receptacle called *sporangium*, which is frequently terminal and aerial. When the spores are 2, 4, 8, or a multiple of 8, they are generally called ascospores, and the cell or spore-case structure containing them is known as an *ascus*.

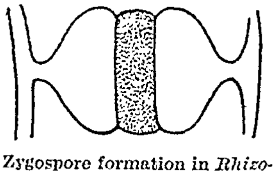
FIG. 1.



Types of ascospores. 1, Saccharomyces; 2-4, Willia; 5, Debaryomyces; 6, Schiönniomyces; 7, Saccharomycopsis; 8, Monospora; 9, Nematospore (after Guilliermond).

2. *Zygospores.*—These spores result from a conjugation or modified sexual act between the two special club-shaped hyphal processes (gametes), which are similar in shape and do not show any apparent sexual differentiations; the gametes come into contact and unite, forming a large cell with a very resistant double wall, called *zygospore*.

FIG. 2.

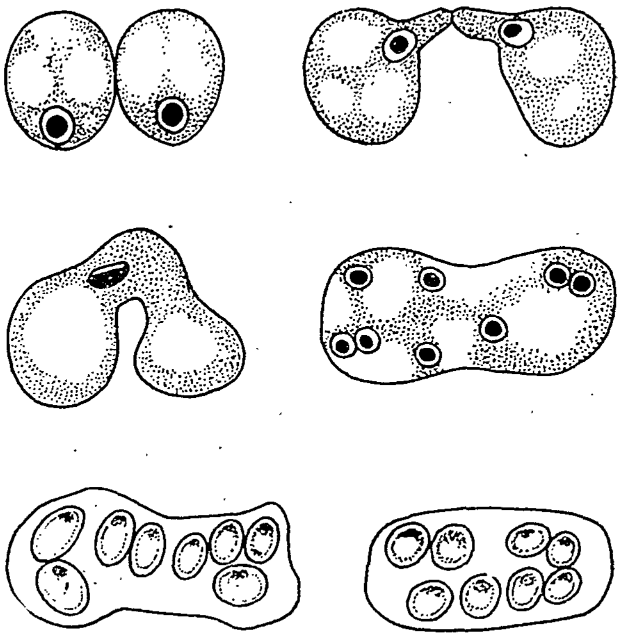


Zygospore formation in *Rhizopus nigricans*.

3. *Oöspores.*—These result from a complete sexual conjugation between sexually differentiated elements—a female element (oösporangium, oögonium) and a male element. The female element, *oösporangium* or *oögonium*, has a thick capsule with several pores, and contains some roundish protoplasmatic masses, female gametes, macrogametes, or oöspheres. The *male element* (male gamete, antheridium), which originates on a special delicate hypha, comes into contact with the oösporangium sending a protoplasmatic process through it. In some cases the antheridium divides into several motile bodies—spermatozoids, antherozoids—which fertilize the female gametes.

4. *Conidia* (Exospores).—These are asexual spores. They are roundish or oval, occasionally spirally shaped bodies, which take origin from the mycelial threads by a process of budding or septation or abstriction, and may be simple or divided by septa. They are at first unicellular (Fig. 4), but later a process of division may set in, and they may become pluricellular. Conidia may be pedunculated or non-pedunculated, lateral or terminal. Two principal types of conidium may be distinguished, the true conidium and the *aleuriospore*. True conidia are easily detached from the mycelial hyphæ bearing them, and when they have become free they originate new spores by a process of budding, or give rise to mycelial filaments by germination. True conidia are incapable of forming new spores or new mycelial threads while they remain attached to the parent mycelium. The mycelial hypha which carries the conidia is termed *conidiophore*, or *Sporophore*; a *phialide* is a flask-shaped segment interposed between the sporophore and the conidia; a *prophialide* is a special article on the Sporophore supporting several phialides. The false conidia, or *aleuriospores*, which may be lateral, terminal, or intercalary, are not originally distinct from the thallus, and are not easily detached; they are only set free by the death of the mycelial hypha to which they are attached.

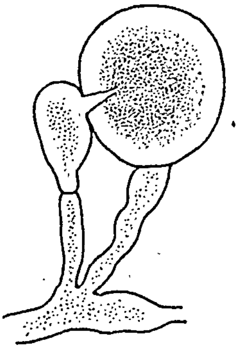
FIG. 3.



Zygosis and ascus formation in *Zygosaccharomyces octosporus* (after Guilliermond).

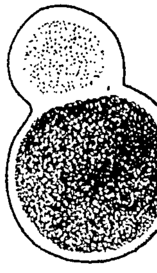
5. *Thallospores.*—A thallospore is merely a portion of the thallus, or vegetative body, which becomes secondarily adapted to the purposes of reproduction. There are several varieties of thallospores, the principal ones being: the *Blastospore* (Fig. 5), oval or roundish, formed by a process of budding. The *Arthrospore*, formed simply by the segmentation and disarticulation of a hyphal element or mycelial thread; it is at first square, and later becomes roundish or oval. The *Chlamydospore*. This is merely an arthrospore of large size undergoing encystment.

FIG. 4.



Oöspore formation.

FIG. 5.



A blastospore (after Vuillemin).

6. *Hemispores.*—The mycelial hypha becomes differentiated, forming an ampulliform structure called "protoconidium," which later divides into several

segments or " deuteroconidia," which are the true reproduction spores

Classification

Fungi may be separated into two large divisions the *Myxomycetes* characterised by the vegetative body being under the form of a multinucleate naked plasmodium and the *Eumycetes* characterised by the vegetative body being generally filamentous Fungi parasitic of man are found only in the second division (Eumycetes), which may be subdivided as follows —

Eumycetes
- Class I —*Fungi Imperfecti* Mycelium septate No ascospores
- Class II —*Ascomycetes* Mycelium septate when present Ascospores
- Class III —*Basidiomycetes* Mycelium septate Basidiospores
- Class IV —*Phycomycetes* —Mycelium non septate in vegetative stage

A *Fungi Imperfecti*

The Class *Fungi imperfecti*, Fuckel, 1869 is most important from a medical point of view It may be subdivided into (*a*) *Deuteromycetes*, Saccardo, 1886 (accessory fructifications present), and (*b*) *Hyphales*, Vuillemin, 1910 (accessory fructifications absent) Only the latter group contains fungi parasitic on man It may be classified as follows —

Hyphales, Vuillemin (= *Hyphomycetes*, Fries)
- Order I —*Microsiphonales*, Vuillemin, 1910 (hyphæ bacilliform)
- Order II —*Thallosporales*, Vuillemin, 1910 (Reproduction by thallospores)
- Order III —*Hemisporales*, Vuillemin, 1910 (Reproduction by hemispores)
- Order IV —*Conidiosporales*, Vuillemin, 1910 (Reproduction by conidia)

The Order *Microsiphonales* contain two families the *Mycobacteriaceæ*, Miche, 1909, in which no definite mycelium is observed, and the *Nocardiaceæ*, Castellani and Chalmers, 1918, in which a definite mycelium is present

The *Mycobacteriaceæ* are generally classified with the bacteria and not with the higher fungi, and contain five principal genera Genus *Mycobacterium*, Lehmann and Neumann, *Leptothrix*, Kutzing *Cladothrix*, Cohn, *Vibriothrix* Cast

The *Nocardiaceæ* contain two genera *Nocardia*, Toni and Trevisan, which grows aerobically, is easily culti vated and produces arthrospores, *Cohnistreptothrix*, Pinoy, which is difficult of cultivation, mostly anaerobic and does not produce arthrospores

The Order *Thallosporales*, Vuillemin, 1910, are divided into two Sub orders the *Blastosporineæ*, in which reproduction takes place by means of blastospores, and the *Arthrosporineæ*, in which reproduction takes place by arthrospores

The Sub order *Blastosporineæ* contain five principal families 1 The *Cryptococcaceæ*, Kutzing The hyphæ are hardly different from the conidia, both being yeast like, conidia not arranged in chains 2 The *Oosporacea*, Saccardo Some long hyphæ present, spores typically in chains 3 The *Enantiothamnaceæ*, Chalmers and Archibald—conidia arranged verticillately around the septa of the mycelial hyphæ 4 The *Haplographiaceæ*—when living parasitic conidia are collected in grape like masses The *Cladosporiaceæ*, Saccardo—conidia solitary or in chains

The Sub order *Arthrosporineæ* contains a very important family, the *Trichophytonaceæ*, Vuillemin in which reproduction takes place by Arthrospores, long hyphæ are present in cultures These fungi are often parasitic of hair This family includes a large number of genera, including Trichophyton, Microsporon, and Achorion It is to be noted, however, that many authorities consider these fungi to belong to the Ascomycetes (family Gymnoascaceæ) and not to the *Fungi imperfecti*

The third Order of the *Hyphales*, the Hemisporales, are characterised by reproduction taking place by hemi spores, here the mycelium is composed of abundant hyphæ, which are thin, but always more than 1 micron in diameter The conidiophores are branched each branch terminating in ampulliform structure preceded by an annular construction produced by a rigid thickening of the wall This ampulliform structure is called proto conidium The protoconidium after a time divides into a number of sporiform segments (deuteroconidia)

The fourth Order *Conidiosporale*, which, as already stated, reproduced by means of conidia, contains four principal Sub orders 1 The *Aleurosporineæ*, Vuillemin 1914 Reproduction takes place by aleurospores 2 The *Sporotrichineæ*, Vuillemin, 1910, reproduction by true conidia, but true conidiophores are absent 3 The *Sporophoralineæ*, Vuillemin, 1910, reproduction takes place by true conidia borne on true conidiophores 4 The *Phialidineæ*, Vuillemin, 1910, reproduction by true conidia borne on phialides

B CLASS II —*Ascomycetes*

The fungi belonging to this class, as already mentioned are characterised by reproduction taking place by means of ascospores (gonidia endospores), which originate inside special cells called asci The Asco mycetes contain three very important families —

(*a*) The *Saccharomycetaceæ*, Rees, 1870, mycelium only slightly developed or absent Asci isolated, not differentiated from vegetative cells

(*b*) The *Endomycetaceæ*, mycelium well developed

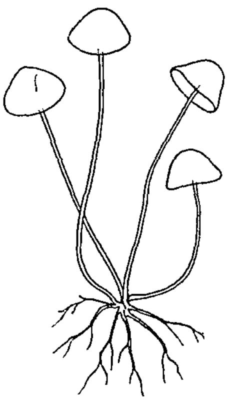
(*c*) The *Aspergillaceæ* asci generally contained in a globose hollow structure (perithecium), with a terminal opening or pore Compact peridium

All these families contain important fungi parasitic of man

C CLASS III —*Phycomycetes*

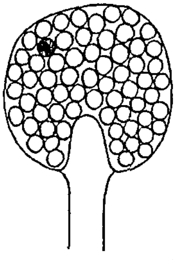
The Phycomycetes, which are characterised by the mycelium being continuous — non septate — in the vegetative stage, contain several families one of which the *Mucoraceæ*, has organisms parasitic of man The fungi belonging to this family have a branching mycelium with *aerial* branches (gonidiophores), each of which supports on its distal extremity a globular, pear shaped, or claviform sporangium, called *gonidangium* which is at first separated *from the gonidiophore by a* septum This septum later protrudes into the lower portion of the sporangium and forms a variously shaped structure known as columella By free cell formation gonidia develop inside the sporangium The sporangial protoplasm not used in the formation of the gonidia is transformed into a peculiar mucilaginous substance which later dries up and is the cause of the sporangium bursting Each gonidium which has become free gives rise by germination to a mycelial filament There is also at times a sexual mode of reproduction consisting in the conjugation of undifferentiated non motile gametes, with formation of zygospores When growing in unfavourable media numerous species repro duce only by conidia and chlamydospores

FIG 6



Rhizopus niger Ciaglinski and Hewelke

FIG 7



Type of sporangium found in Genus *Rhizopus*

The family *Mucoraceæ* contains a number of genera, among which the *following have species parasitic of* man (see Figs 6 and 7) 1 *Mucor*, Micheli, mycelium ramified rhizoids (slender root like filaments) absent

2. *Rhizomucor*, Lucet and Constantin; rhizoids present, columella ovoid. 3. *Rhizopus*, Ehrenberg; rhizoids present, columella mushroom-like. 4. *Lichtheimia*, Vuillemin; peduncle supporting sporangium ends in a special formation encircling the base of the columella. Diseases due to the fungi of the family *Mucoraceæ* are often called "mucormycoses."

Certain Biological and Biochemical Characters of Fungi.

The *biological* and *biochemical* characters of fungi are very interesting, and of great practical importance. Recent investigations have shown numerous analogies with the lower fungi (bacteria), as regards production of toxins, and especially as regards serological reactions developing in inoculated animals.

About 20 years ago, the late Dr. A. Macfadyen, Director of the Lister Institute, inoculated rabbits with cultures of a saccharomyces and observed a production of specific agglutinins in the blood for the particular species he had inoculated. These results were confirmed and enlarged, using other fungi, by G. H. Rogers, Concetti, Quarelli, &c., and Widal and Abrami have described a general diagnostic method, "sporo-agglutination method," based on the observation that patients suffering from mycological diseases contain specific agglutinins for the spores of the causative fungi. In my experience, however, in many cases, in addition to specific agglutinins, there is present also a large amount of non-specific ones, and this generally detracts from the usefulness of the method.

As regards *toxins*, Auchair and Verliac have obtained a toxic product soluble in ether from *Nocardia bovis*, which they called "actinimycetine." Ceni, Besta, and other observers have extracted various toxins from fungi of the genus Aspergillus, and believe them to be the cause of pellagra. Charrier, Roger, and others have extracted toxins from fungi of the genus Monilia.

Vaccines have been prepared using cultures of Monilias killed by heat, or by carbolic acid by Ashford, Taylor, and others. Plato has prepared a trichophyton vaccine by killing cultures of various trichophytons by heat and triturating them. When injecting this vaccine in patients affected with ringworm, he has observed a general reaction similar to that induced by tuberculin in tuberculous patients. A cuti-reaction in patients suffering from sporotrichosis has been described by De Beurmann.

Biochemical Changes Induced by Fungi.

Certain fungi may induce profound chemical changes, and are of great importance in agriculture and industry. Everyone knows the rôle played by organisms of the family *Saccharomycetaceæ* in alcoholic fermentation and in the production of wine and beer. Certain fungi ferment a large number of sugars and other carbohydrates, others a few or none. I have happened to find a group of monilias which very rapidly split a substance generally considered to be non-fermentable—viz., inulin.

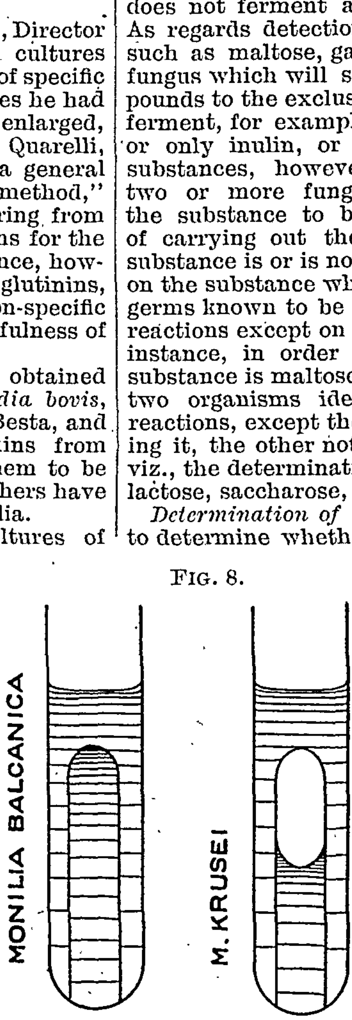
Mycological Method to Detect Various Carbohydrates.

As well known, the property certain fungi have of fermenting glucose has been used for many years as a method of routine to detect this sugar in the urine. In this connexion I may perhaps be allowed to describe briefly a mycological method for the detection of other sugars and carbohydrates which I theoretically devised some years ago, but only recently worked out experimentally, jointly with Dr. F. E. Taylor, in Professor Hewlett's institute. It may, perhaps, be of some slight interest to give here some details of this method and make it better known.

As already stated, for many years so-called German yeast (baker's yeast, brewer's yeast) has been used for the detection of glucose, but this is the only substance for which so far such method of detection has been employed in pathological investigations, and, as a matter of fact, this method of finding glucose (although considered specific in some text-books on pathology) is inexact, because Taylor and myself have shown that German yeast ferments as a rule, not only glucose, but also lævulose, galactose, maltose, saccharose, and sometimes even lactose. If a specimen of urine undergoes fermentation after the addition of German yeast it does not mean, therefore, that this urine contains glucose; it might contain lævulose or galactose, or maltose or saccharose, or even lactose, &c. To detect and determine with certainty glucose it is necessary to use an organism which will split only this sugar and no other. We have such an organism in *M. balcanica*, Cast., which does not ferment any substance apart from glucose. As regards detection and identification of other sugars such as maltose, galactose, &c., I do not know of any fungus which will select only one of the carbon compounds to the exclusion of all others, a fungus which will ferment, for example, only maltose, or only galactose, or only inulin, or only lactose, &c. These various substances, however, may be identified by using two or more fungi, and comparing their action on the substance to be determined. The simplest way of carrying out the method to determine whether a substance is or is not a certain carbohydrate, is to test on the substance whenever possible the action of two germs known to be identical in all their fermentative reactions except on that particular carbohydrate. For instance, in order to see whether a given chemical substance is maltose, the substance may be tested with two organisms identical in all their biochemical reactions, except their action on maltose, one fermenting it, the other not. I shall make a few examples—viz., the determination of lævulose, maltose, galactose, lactose, saccharose, inulin.

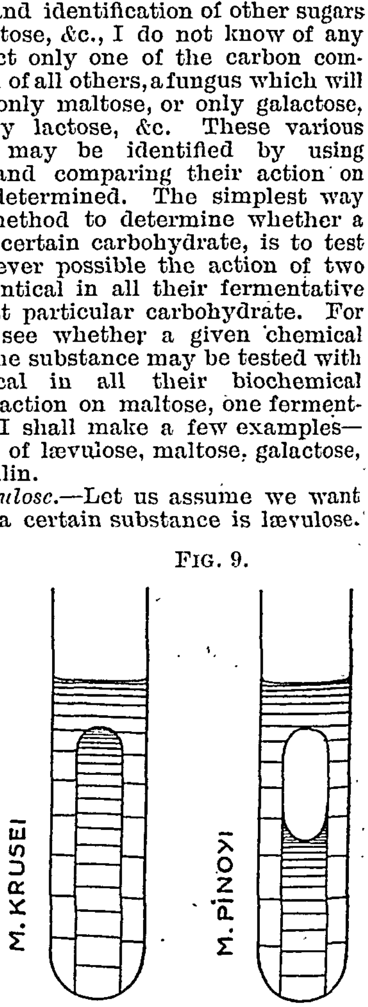
Determination of lævulose.—Let us assume we want to determine whether a certain substance is lævulose.

FIG. 8.



Identification of lævulose.

FIG. 9.



Identification of maltose.

A 1 per cent. sterile solution of the substance is made in sugar-free peptone water, and distributed into two tubes (Nos. 1 and 2), each containing a fermentation tube. No. 1 is inoculated with *Monilia krusei*, Cast., and No. 2 with *Monilia balcanica*, Cast. (see Fig. 8). The tubes are incubated at 35° C. for 48 hours, and the results are then read. If No. 1 tube (*Monilia krusei*, Cast.) contains gas, and No. 2 tube (*Monilia balcanica*, Cast.) contains no gas, the substance is lævulose. This is easily understood by keeping in mind the following facts: *Monilia krusei* ferments only glucose and lævulose; *Monilia balcanica* ferments only glucose. The substance we are testing having been fermented by *Monilia krusei* must therefore be either glucose or lævulose, but as it is not fermented by *Monilia balcanica* it cannot be glucose, which is always attacked by that fungus: it can, therefore, only be lævulose.

Determination of maltose —A 1 per cent sterile solution is made in sugar free peptone water of the substance which we wish to ascertain whether it is maltose The solution is distributed into two sterile tubes, which are labelled Nos 1 and 2 (see Fig 9) No 1 tube is inoculated with *Monilia pinoyi*, Cast, and No 2 with *Monilia krusei*, Cast If after 48 hours' incubation at 35° C No 1 (*Monilia pinoyi*) contains gas, and No 2 (*Monilia krusei*) does not, the substance is maltose This is explained by the fact that *Monilia pinoyi*, Cast, ferments only three carbon compounds I know of—glucose, lævulose, maltose, *Monilia krusei* ferments only two—glucose and lævulose The substance being fermented by *M pinoyi* might be either glucose or lævulose or maltose, but it is not fermented by *M krusei* it cannot therefore be glucose or lævulose, and there remains only one possibility, it must be maltose

Identification of galactose —Same technique, but No 1 tube is inoculated with *Monilia metalondinensis*, Cast, and No 2 tube with *Monilia pinoyi*, Cast If after 48 hours' incubation at 35° C No 1 tube (*M metalondinensis*) contains gas and No 2 tube (*M pinoyi*) does not, the substance must be galactose The explanation lies in the fact that *M metalondinensis* ferments the following four carbon compounds only (glucose, lævulose, maltose, galactose), while *Monilia pinoyi* ferments only glucose, lævulose, and maltose The substance being fermented by *Monilia metalondinensis*, there are four possibilities it may be glucose or lævulose, or maltose, or galactose, but is not fermented by *M pinoyi* (which attacks glucose lævulose, and maltose), it cannot, therefore, be glucose, nor lævulose, nor maltose, it can only be galactose

Determination of lactose —Same technique as for the determination of the carbohydrates already mentioned but instead of using micro organisms belonging to the higher fungi, bacteria may be used The substance to be identified is made into a 1 per cent sterile solution of peptone water and distributed into two tubes Nos 1 and 2 Tube No 1 is inoculated with *B pseudoasiaticus*, Cast, and tube No 2 with *B pseudocoli* If after 48 hours' incubation at 37° C tube No 1 (*B pseudoasiaticus*) does not contain gas, while tube No 2 (*B pseudocoli*) contains gas, the substance must be lactose, because *B pseudoasiaticus* and *B pseudocoli* are absolutely identical in all their fermentative characters except as regards lactose, which is not attacked by *B pseudoasiaticus*, and is, on the other hand, fermented with production of gas by *B pseudocoli*

In practice, if it is known beforehand that the substance to be determined is Fehling reducing, two bacilli found in every laboratory may be used—viz, *B paratyphosus B* and *B coli* If a Fehling reducing substance is not fermented by *B paratyphosus B*, and is fermented by *B coli*, it is lactose Why? Because the two germs as regards fermentation of Fehling reducing substances, differ only in their action on lactose *B paratyphosus*, as well known does not ferment it, while *B coli* ferments it [1]

Determination of saccharose —A 1 per cent solution of the substance suspected to be saccharose is made in sugar free peptone water, and some of the solution is placed into tubes Nos 1 and 2 Tube No. 1 is inoculated with *Monilia tropicalis*, Cast, and tube No 2 with *Monilia metalondinensis*, Cast If gas develops in tube 1 (*Monilia tropicalis*) and not in tube No 2 (*Monilia metalondinensis*) the substance is saccharose This is easily understood if the following facts are kept in mind *Monilia tropicalis* ferments only the following carbon compounds glucose, lævulose, maltose, galactose, saccharose *M metalondinensis* only the following four carbon compounds glucose, lævulose, maltose, galactose If a substance is fermented by *M tropicalis*, there are therefore five possibilities it may be glucose or lævulose, or maltose, or galactose, or saccharose but if the same substance is not fermented by *M metalondinensis*, it cannot be glucose, or lævulose, or maltose, or galactose, and must therefore be saccharose

To the above purely mycological method a chemico mycological formula, useful in practice, may be added.

$$\left.\begin{array}{ll}\text{Fehling} & - \\ \textit{Monilia tropicalis}\text{, Cast} & + \end{array}\right\} = \text{Saccharose}$$

This is explained by the fact that *M tropicalis*, Cast, ferments with production of gas, glucose, lævulose, maltose, saccharose, and no other substance If Fehling is negative it cannot be any of the first three substances, as they are all Fehling reducing, and it must therefore be saccharose

Determination of inulin —Same technique as for saccharose, but tube No 1 is inoculated with *Monilia macedoniensis*, and tube No 2 with *Monilia rhoi* If gas appears in tube No 2 (*M rhoi*) the substance is inulin This is easily understood if one bears in mind the fact that *M macedoniensis* and *M rhoi* are identical in all their fermentative reactions except in inulin, which is fermented by *M macedoniensis*, but not by *M tropicalis* If a substance, therefore is fermented with production of gas by *M macedoniensis* and not by *M rhoi* it must be inulin

Presence of More than One Fermentable Substance.

If more than one sugar or other fermentable carbon compound is suspected to be present, this may to a certain extent be ascertained and the various fermentable substances determined by the mycological method Let us assume that a liquid after gas fermentation with *Monilia balcanica*, Cast, is still fermentable with production of gas by *Monilia krusei*, Cast, the conclusion is that in addition to glucose the liquid contained lævulose of course, care should be taken to use strains of *Monilia balcanica* and *Monilia krusei* having approximately the same fermentation power on glucose If now the liquid after exhaustion first with *Monilia balcanica*, Cast, and then with *Monilia krusei*, Cast, is fermentable with production of gas by *Monilia pinoyi* Cast, the presumption is that, in addition to glucose and lævulose, maltose was present, and this is easily understood if we remember that *Monilia balcanica* produces gas in glucose only *Monilia krusei*, Cast, in glucose and lævulose, and *Monilia pinoyi*, Cast, in glucose, lævulose, and maltose

Use of the Mycological Method in Urine Analysis

With Dr F E Taylor I have carried out a number of experiments, adding to samples of urine various sugars and other carbohydrates and also examining a certain number of pathological urines The conclusion we have come to is that the method can be used in urine analysis with advantage, especially in the detection of glucose, lævulose, maltose galactose, lactose and pentoses A point of great importance is that the urine should be aseptic if it cannot be collected aseptically it should be sterilised as soon as possible after distribution in the tubes, in Koch's steamer for 30 minutes on two consecutive days It should never be autoclaved, as this procedure may alter the characters of the sugars present A portion of the urine is distributed in five sterile tubes, each containing a Durham's fermentation tube A third or equal amount of sugar free peptone water should be added to the urine, otherwise the fungi may grow very scantily and there may be no production of gas The five tubes plugged with sterile cotton wool, are inoculated one with *Monilia balcanica*, one with *Monilia krusei*, one with *Monilia pinoyi* one with *Monilia metalondinensis*, one with *B paratyphosus*, and one with *B coli*

Addendum

Unfortunately some months ago an accident, the catching fire of the 20° C incubator in which the collection of monilias was kept, destroyed a number of important strains including *Monilia balcanica*, Cast, which is specific for glucose At the present time only the following monilias with permanent fermentative reactions are available for urine analysis, *Monilia krusei*, Cast (ferments with production of gas, glucose and lævulose), *Monilia tropicalis*, Cast (ferments with production of gas, glucose, lævulose, maltose, galactose, and saccharose); *Monilia macedoniensis*, Cast. (ferments, with production of gas, glucose, lævulose, galactose, saccharose, and inulin). However, even with three species, in conjunction with *B. paratyphosus B* and *B. coli*, several carbohydrates can be detected and identified, as shown by the following formulæ:—

---

[1] It is often stated in text books that if a urine reduces Fehling and is not fermented by ordinary Baker's yeast (German yeast) the reducing substance is lactose There are however two important sources of error first quite a number of specimens of German yeast ferment lactose second even if the German yeast should not ferment lactose this is not the only Fehling reducing substance which may not be fermented by baker's yeast—the pentoses for instance

Monilia krusei, Cast.	+	= Glucose or lævulose.
Monilia macedoniensis, Cast.	0	= Maltose.
Monilia tropicalis, Cast. ...	+	
Monilia macedoniensis, Cast.	+	= Inulin.
Monilia tropicalis, Cast. ...	0	
Monilia krusei, Cast.	0	= Galactose.
Monilia macedoniensis, Cast.	+	
Monilia tropicalis, Cast. ...	+	
B. paratyphosus B, Shott....	+	
Monilia macedoniensis, Cast.	+	= Saccharose.
Monilia tropicalis, Cast. ..	+	
B. paratyphosus B, Shott....	0	
Monilia tropicalis, Cast. ...	0	= Lactose (most probably, but it might be raffinose or glycerine; test with Fehling; if positive, lactose).
B. paratyphosus B, Shott ...	0	
B. pseudocoli, Cast....	+	
Monilia tropicalis, Cast. ...	0	= *Pentoses (if Fehling, positive).*
B. paratyphosus B, Shott	+	
B. coli	+	

+ = presence of gas. 0 = absence of gas; acid fermentation is not taken into account.

For urine analysis it is advisable to use as a matter of routine a set of five tubes, one inoculated with *M. krusei*, one with *M. macedoniensis*, one with *M. tropicalis*, one with *B. paratyphosus B*, and one with *B. pseudocoli*. The results may be arranged as follows:—

Monilia krusei, Cast.	+	= Glucose (or lævulose).
Monilia macedoniensis, Cast.	+	
M. tropicalis, Cast.	+	
B. paratyphosus B, Shott ...	+	
B. pseudocoli, Cast....	+	
Monilia krusei, Cast.	0	= Maltose.
M. macedoniensis, Cast. ...	0	
M. tropicalis, Cast....	+	
B. paratyphosus B, Shott ...	+	
B. pseudocoli, Cast....	+	
M. krusei. Cast.	0	= Galactose.
M. macedoniensis, Cast. ...	+	
M. tropicalis, Cast....	+	
B. paratyphosus B, Shott ...	+	
B. pseudocoli, Cast....	+	
M. krusei, Cast.	0	= Lactose (most probably, but it might be raffinose or glycerine; test with Fehling; if positive, lactose).
M. macedoniensis, Cast. ...	0	
M. tropicalis, Cast....	0	
B. paratyphosus B, Shott ...	0	
B. pseudocoli, Cast....	+	
M. krusei, Cast.	0	= Pentose (provided Fehling be positive).
M. macedoniensis, Cast. ...	0	
M. tropicalis, Cast....	0	
B. paratyphosus B, Shott ...	+	
B. pseudocoli, Cast....	+	
M. krusei, Cast.	0	= Saccharose.
M. macedoniensis, Cast. ...	+	
M. tropicalis, Cast....	+	
B. paratyphosus B, Shott ...	0	
B. pseudocoli, Cast....	+	
M. krusei, Cast.	0	= Inulin.
M. macedoniensis, Cast. ...	+	
M. tropicalis, Cast....	0	
B. paratyphosus B, Shott ...	0	
B. pseudocoli, Cast....	0	

+ = presence of gas. 0 = absence of gas; acid fermentation without production of gas is not taken into account.

I venture to think that this method, when more generally known, will, perhaps, be found useful in the detection of those sugars and carbohydrates the identification of which is long and laborious when made by purely chemical methods.

Having to-day referred to the morphological characters of fungi and their classification, as well as, though very incompletely, to their biological and biochemical properties, I propose, with your permission, to deal in the next lecture with fungi as specific causes of disease.

DR. A. T. SCOTT, M.B.E., Assistant Commander, Y Division Metropolitan Special Constabulary, has been made an Honorary Associate of the Order of St. John of Jerusalem for services to wounded, &c., during air raids.

A REVIEW OF "HEART" CASES IN THE EGYPTIAN EXPEDITIONARY FORCE, 1916-1918.

BY A. L. KROGH, M.D. EDIN., W. T. RITCHIE, M.D. EDIN., AND E. H. WHITE, M.D. OXON.

DURING a period of two years from November, 1916, 2425 soldiers suffering, or supposed to be suffering, from affections of the heart came under our care in Cairo. Some were men of category B, sent to hospital from garrison battalions or from area employment companies; but the vast majority belonged to category A, and had gone sick while with their units in the Sinai Desert, in the maritime plain of Palestine, in the Judæan Hills, or in the Jordan Valley. Many, and particularly those observed during the winter of 1916–1917, had previously seen service in Gallipoli. The nature of the campaign in Egypt and in Palestine offered abundant possibilities for the development of cardiac affections. The prolonged desert campaign, its weary monotony unbroken by leave even to the base, or unrelieved for weeks by letters from home, and the strain of marching and of fighting, ankle deep in sand, while exposed to the heat of the sun and the glare of the desert, and with a scanty water-supply, afforded a stiff test of endurance. Moreover, acute infective diseases were prevalent, especially malaria, enteritis, bacillary and amœbic dysentery, diphtheria, sand-fly fever, enteric, paratyphoid, and relapsing fever of the European and of the Palestine forms. Typhus, and jaundice apart from malaria, were not frequent; trench fever and dengue were practically not-existent.

Other Diseases.

Amidst the stress of work there was a tendency when disposing of men who, although unfit, had no organic disease of the heart, to base the diagnosis upon the obvious sign of an unduly rapid pulse, while they might in reality be suffering from malaria, chronic dysentery, anæmia, bronchitis, pulmonary tuberculosis, or other disease. Our general principle was to search for the basal disease and not to retain a diagnosis of D.A.H. unless that search—including, if necessary, an examination of the blood, of the fæces, and of the sputum, a screen examination of the chest, a diagnostic injection of tuberculin, and other methods—had failed to establish a diagnosis. "Other diseases" constituted 12·4 per cent. of the total 2425 cases. An analysis of 1132 cases admitted with a diagnosis of D.A.H. shows that 185 (16·3 per cent.) were suffering from "other diseases." Physical examination and the response to effort warranted a diagnosis of "No appreciable disability" in 36 (3·2 per cent.). In some of these men there may have been a disability which we failed to detect, or it may have passed away during the period between the evacuation of the men from their units and their arrival at hospital; but a considerable number had certainly no disability. A man reported sick with scabies, a sprained ankle, mild diarrhœa or other complaint, and subsequently a physiological irregularity of the pulse, or some slight deviation from the assumed standard of the cardiac sounds, was mistaken for a sign of heart disease. We have no hesitation in saying that faulty diagnosis was responsible for the transfer to hospital of many men who had no cardiac disability. Further, in many men admitted as V.D.H. or as D.A.H. the symptoms were trivial, and yet they had become profoundly impressed by the belief of the heart being seriously diseased.

In 149 (13·1 per cent.) of 1132 cases admitted as D.A.H. we diagnosed debility in 32, the condition being usually that of convalescence from dysentery, diphtheria, or other acute infective disease, bronchitis in 15, neurasthenia in 12, phthisis in 11, anæmia in 11, malaria in 8, sand-fly fever in 6, diphtheria, pulmonary emphysema, and myalgia (each) in 4, tubercle of the lung, pleurisy, and dysentery (each) in 3. "Other diseases" of lesser frequency were tonsillitis, dilatation of the stomach, diarrhœa, paratyphoid, adenoids, asthma, congestion of the lung, disseminated sclerosis, multiple (post diphtheritic) neuritis, hysteria, epilepsy, astigmatism, exophthalmic goitre, myxœdema, obesity, nephritis, gonorrhœa, secondary syphilis, P.U.O., kyphosis, rheumatic fever, inflammation of joints, varix, flat foot, and cancer.

The diagnosis of phthisis or of tubercle of the lung was sometimes easy. For example —

A lance corporal, aged 24, a motor driver in civil life, had been in hospital twice for bronchitis during his three and a half years of service before he was admitted as D.A.H. He complained of shortness of breath, cough, expectoration, and giddiness, the pulmonary physical signs were distinct and the sputum contained tubercle bacilli.

Another patient, aged 20, and formerly a tailor, had suffered from relapsing fever after being overseas for 15 months, and thereafter had never been wholly fit. Sixteen months later, complaining of weakness, palpitation, and shortness of breath, he was admitted as D A.H He was anæmic, the apex of the left lung was consolidated, and he lost 11 lb in weight while in hospital.

Other cases were less definite, having tachycardia and signs of a quiescent pulmonary lesion, but had not lost weight and did not react to 0 001 c cm. of tuberculin (T.O.); and in some instances the true diagnosis was not established until several months after D A.H. had first been diagnosed.

One man, aged 20, formerly a bank clerk, was under our care for seven weeks during the summer of 1917, and was discharged as fit for category A. Six months later he was readmitted as D.A.H , complaining of shortness of breath and giddiness. At rest his pulse rate was 78, after exertion 120, and five minutes later the rate was still 120 Ten months after his disability was first diagnosed as D A.H ; the right apex showed signs of consolidation

Examinations and Tests.

All the men, with few exceptions, were admitted to a general hospital, and many arrived as cot cases. We realised that a prime essential in treatment was the restoration of the man's confidence in his heart. A brief examination of his colour, of his breathing, and of his pulse as he lay on the stretcher having satisfied us that he had no serious heart failure, irrespective of what the cardiac lesion might be, he was asked to rise and walk to the ward. Thus the first step towards recovery was made. In our subsequent examination an inquiry, as full as possible, was made of the man's symptoms, of his habits in civil life, of antecedent diseases, and particularly of acute or chronic infections. The respiratory, the nervous, and other systems were examined before a detailed examination was made of the circulatory system, with the object of excluding diseases other than those of this system.

The men were examined in the recumbent and in the erect postures, before and after exercise. In determining the size of the heart we relied more on the situation of the apex beat than on the percussion dullness of the heart. Postural variations in the character of the cardiac sounds and murmurs were always noted. For example, the disappearance of a basal systolic murmur on change of posture reveals its functional origin Again, in mitral stenosis the characteristic murmurs may be obscure until the patient is erect and leaning forward, or they may not be heard clearly until he lies on his left side The value of exercise in intensifying cardiac murmurs is best illustrated in mitral stenosis, and in the mitral and tricuspid incompetence of cardiac dilatation Respiratory irregularity of the pulse was often observed, especially in men below 30 years of age. In those over 30 this irregularity was often associated with a recent infection or with a neurosis This irregularity was not an absolute criterion of the men's tolerance of effort, more especially in cases of neurosis or if the pulse rate at rest exceeded 90. In men with a history of recent infection a respiratory irregularity of the pulse was likewise no criterion of the immediate tolerance of effort, but it afforded a basis for confidence in anticipating complete recovery and return to duty. The pulse rate was taken in the recumbent and in the erect postures, and a note made of symptoms, such as blurred vision, giddiness, and præcordial uneasiness on rising from the couch.

Men who had developed D A.H in the early stages of convalescence from diphtheria, dysentery, or other acute infection were not submitted to any tests or course of training until their general health was substantially restored. After the first few weeks of convalescence, however, a course of mild physical exercises was of great benefit Except in those acute cases the men were never confined to bed, but were up and attending dining hall, and they were given as much liberty as possible. Having been examined they were tested as soon as possible after their admission to hospital.

The initial test of the heart's capacity for exertion varied according to the man's physical condition, but the usual standard test was that of walking 50 yards and doubling back. In the more obviously distressed men and in those with pronounced tachycardia milder initial tests were employed, such as swinging of the arms and skipping 20 times In the evaluation of the response to effort we particularly noted the pulse rate after exertion, its period of decline, which should not exceed 2 minutes, pallor, dyspnœa, distress, palpitation, pain, and development of cardiac murmurs and extrasystoles. According to the nature of the response the reaction was noted as good, fair, or poor If the pre exertion rate was over 90 the reaction was seldom wholly satisfactory at the outset In a considerable number the pulse-rate two minutes after the test exercise was less than the pre exertion rate, in the absence of dyspnœa and other symptoms this was a favourable sign, and indicated that improvement would accrue from a course of exercises

Graduated Training.

Within a day or two of admission to hospital the men began a course of graduated physical exercises. The first part of the course, consisting of exercises A to C 1, C 2, of 15 to 30 minutes' duration daily, as detailed in the Report (No. 8) to the Medical Research Committee (1917), was carried out in the hospital. Men who failed to attain the standard of efficiency required for category B III. were invalided home; others who proved fit for B III., but were not likely to be fit for a higher category (for example, men with mitral stenosis and good tolerance of exercise), were classified B III. for sedentary duties, and discharged to their base. The vast majority of the men, however, became fit for half an hour's exercise in groups C 1, C 2, and were then transferred from hospital to a depôt for further testing and training.

During 1917 these men were transferred to a convalescent depôt, where, in addition to half an hour's daily exercise in C 1, C 2, or in D group, they had a daily march of about half an hour over level ground and at an even pace. Later this was supplemented by route marches of two to six miles thrice weekly, over sandy ground, the men eventually carrying equipment. In 1918 the men were transferred from hospital to a command depôt, where the standard of efficiency demanded of the men approached as closely as possible that required for categories B II., B I., and A on active service. The heart cases were not separated in any respect from others in the depôt, but were exercised and trained along with other men with divers complaints. This was a fundamental principle in treatment, in order to prevent the men from thinking they were special cases, and in order to divert their attention from the heart. Four groups of physical fitness and of training were established in the command depôt. On transfer there most men were placed in the lowest group—namely, in group 4. Here they performed light fatigues, and each morning had two courses of special physical exercises, each of 20 minutes' duration. These exercises, performed under the direction of an expert instructor in physical training, Dr. G. G. Deaver, were characterised by their easy rhythmical motion, graduated both in tempo and in force, and by being carried out to the music of a band. The "heart" cases remained in this group for six days. They were then transferred to group 3, in which the men had, in addition to similar exercises of 30 minutes' duration daily and fatigues, a two-mile route march on alternate days. The duration of stay in this group was ten days, and then the men automatically moved into group 2, in which parades, drill, and Swedish drill were carried out, with longer route marches. After eight days in group 2 the men passed into group 1, in which they had full drills, ceremonial and otherwise, on alternate days; eight-mile route marches, with full equipment, pack and rifle, and bayonet fighting. The period of stay in this highest group was ten days. The average duration of training in the command depôt was consequently about 34 days. In was found inadvisable to allow cases to drag on indefinitely in the depôt. If little or no improvement was obtained in six weeks the man was regraded and discharged to duty in a lower category. It was better that he should be doing useful work in category B II. or B I. than remain in the command depôt in the hope of eventually attaining category A. No man was discharged from the depôts until he had been proved fit for the duty of his category.

The route marches afforded a sound test of the men's capacity for sustained effort, and were a necessary link in the chain of observation, for although a patient might tolerate even the strenuous exercises of D group, he might fail when the test was one of endurance, as demanded by a route march. In such men the phenomena of exhaustion were shown by limpness, fatigue, profuse sweating, laboured breathing, rapid pulse, loss of colour, and a feeling of being "done up." Other men made a poor start, but improved remarkably during the march, and returned in a comparatively fresh condition. Apparent anomalies in the men's response to effort were often observed, for this depended on the quality or nature of the effort demanded. Thus a man may tolerate well a sustained test such as a route march, yet react very poorly to a mild skipping test, to a short sprint, or to tests which involve jerking or sudden postural changes, and consequently sudden variations of arterial and venous pressure in the splanchnic area.

Organic Disease of the Heart.

Of the total 2425 cases 355 (14·6 per cent.) had organic disease of the heart. In all but a few, who had cardiac hypertrophy or chronic myocarditis, the disability was an organic valvular lesion. A loud pulmonary systolic murmur, as the chief abnormal sign, was often noted in men who were anæmic or in whom the heart was dilated, but only one instance of congenital heart disease came under observation.

The case was one of patent ductus arteriosus in a man aged 23, a tailor's cutter in civil life, who had three years and nine months' service, including two years in Gallipoli and in Egypt, before he reported sick with bronchitis. Of the acquired valvular lesions mitral incompetence was more common than all others combined; mitral stenosis was more frequent than aortic incompetence. The lesions were associated with all grades of cardiac reserve force. An infantryman presenting aortic incompetence had two and a half years' service, one year being overseas, and he was fit for full duty until he sprained his ankle; a second, with facial manifestations of congenital syphilis, had for nine months been fit only for light duty in the cook-house; while a third died of acute endocarditis of the aortic valve after seven days' illness. The men with organic disease of the mitral valve likewise differed in their capacity for exertion, and in many this was remarkably good. In illustration we may cite the case of a lance-corporal who had suffered from rheumatic fever nine years previously, but from no subsequent illness, and who had made a desert march of 15 miles six months before he was evacuated to hospital on account of mitral stenosis. But others had long been ailing; for example, a private, aged 37, who had been breathless since he had scarlet fever at the age of 14, and who presented the characteristic signs of mitral stenosis and incompetence.

In the differentiation of mitral incompetence as a result of organic disease from that of cardiac dilatation we relied mainly on a history in civil life of acute infective disease, and particularly of rheumatism, on downward or outward displacement of the apical impulse, and on the quality and persistence of the apical systolic murmur. In the mitral incompetence of cardiac dilatation we usually found a history of a recent acute infection (diphtheria, dysentery, malaria, &c.) and signs of anæmia; the left ventrical was not hypertrophied, there were usually coincident systolic murmurs at the pulmonary and tricuspid areas, and the murmurs lessened or disappeared with rest, to reappear after exertion. Moreover, the murmurs of cardiac dilatation, as a rule, disappeared entirely when the patients' general health was restored, whereas those of organic nature persisted throughout the patients' stay in hospital and in depôt.

In all cases of valvular disease and of cardiac dilatation, except those obviously unfit, the heart's functional capacity was tested in the manner already described. Men with aortic incompetence were invariably invalided home. Most of those with mitral stenosis were found, after a few days' testing in hospital, to be fit for the lighter grades of physical exercise. They were usually classified B III., and discharged to sedentary duties; only a few were transferred to the depôt for further testing and training, for it was seldom considered desirable to place even the fittest of them in a category higher than B III. Most of the men with mitral incompetence were found to tolerate the lower grades of exercise well, and were transferred to the depôt; nearly a half of those transferred were eventually classified B II.

Degeneration of the myocardium and chronic myocarditis were rarely observed, although arterial sclerosis was common in the elderly men of garrison battalions and labour corps. Auricular flutter was observed in only one man.

This patient was 31 years of age, had been a bookmaker's assistant in civil life, and had enjoyed uniformly good health. After ten months' service in France he was wounded in the arm. Seven months later he was graded B II, and while employed in a supply depôt at Kantara, began to complain of præcordial pain, dizziness, breathlessness, and sleeplessness The arteries were thickened, the heart was not enlarged, and its sounds were pure, the auricles were fluttering at a rate of 200 per minute, the ratio of auricular to ventricular systole being inconstant He was never confined to bed, and never had any urgent symptoms during two months' stay in hospital before he could be invalided

Auricular fibrillation was observed in two cases, but no case of alternation, of heart block, or of nodal (atrio ventricular) rhythm came under our care

Disordered Action of the Heart

Of the total cases 1774 (73 per cent) were returned as D A H. The symptoms and physical signs of these cases corresponded with those described in other theatres of the war, or with D A H. as seen in civil practice, and need not be detailed Five groups of cases were differentiated 1. The toxo metabolic group, with a definite history of infection, and with toxæmia and often disorders of metabolism resulting therefrom This group was subdivided into (*a*) Type general, with wide spread toxæmia, lowering of the general health, and the exhaustion syndrome, and (*b*) type cardiac, with symptoms and signs referable mainly to the circulatory system and its nervous control 2 Cases with minor degrees of arterio sclerosis, about 2 per cent. of the total cases. 3 Neurosis 4 Effects of strain. 5 The immature or untrained heart

Infection was by far the most potent factor in the ætiology of D A H, but neither in the toxic or metabolic group of cases, nor in those in whom the primary disability was a neurosis, were there any signs indicating hyperthyroidism In a series of 717 cases special inquiry elicited a clear history of acute infection in 41 4 per cent, while 50 per cent either gave a history of infection or were affected with anæmia, which was probably of infective origin Of the causal infections, the most frequent were diphtheria (9 4 per cent), rheumatic fever and chorea (6 7 per cent), dysentery (3 9 per cent), bronchitis (3 8 per cent), malaria (3 1 per cent), tonsillitis (3 0 per cent), scarlet fever (2 4 per cent), pneumonia and enteric (each 1 2 per cent) In very few of our cases was D A H a sequel of gas poisoning, in none was it caused by trench fever Of all the common forms of D A H, that arising as a late sequel of diphtheria was the most severe, persistent, and intractable As demonstrating the importance of this disease in the causation of D A H, we note that of 531 cases of diphtheria admitted to the hospital in 1917, 12 per cent developed transient D A H during early convalescence, and that of a total 530 "heart cases admitted during the period July to December of the same year, 72 (13 5 per cent) were post diphtheritic D A H It was not considered advisable to give to cases convalescing from diphtheria any course of training in the hospital The more severe cases, when semi convalescent, were transferred to another hospital for further rest, the lighter cases were retained in hospital for not less than six weeks from the onset of the primary disease, and before being transferred to the convalescent depôt they were classified "B III for two or three months after convalescence" In appropriate cases an entry was made in the man s pay book of his being unfit for fatigues or for marching The best treatment of post diphtheritic D A H is prophylaxis

D A H was more often post dysenteric than post malarial, and the latter was less severe and less persistent, though we occasionally observed acute, and in two instances fatal, heart failure in the course of malignant malaria Further evidence of the relative infrequency of malaria as a cause of D A H is afforded by the statistics of the medical division of the hospital for 1917, the total admissions for malaria being 1539, as contrasted with 960 for dysentery and 1336 for enteritis and diarrhœa and also by the returns for 1918 when there were only 1358 cases of dysentery as against 5879 cases of malaria for the first 10 months of the year. Moreover, during the last quarter of 1918, when malaria was most prevalent and severe, D A H. was almost a rarity The explanation of the greater frequency and severity of post dysenteric D A H is probably the profound toxæmia associated with the intestinal infection of bacillary and of amœbic dysentery Of 2318 cases of dysentery, 353 (15 per cent) were amœbic

Neurosis —In only 2 5 per cent of 717 cases of D A H was there a definite history of shell or bomb explosion In a further 2 3 per cent the disorder was essentially a neurosis, the most striking examples being in men of Celtic type Anxiety, tremor, and exaggeration of the tendon reflexes were specially pronounced, the pulse rate remained persistently high and was unduly accelerated by slight sympathetic stimulation, dyspnœa was trivial or absent even although the respirations were accelerated to three or four times their normal rate Rest in bed was of no benefit and might even be prejudicial During their course of training in the depôt the men of the neurosis group presented persistent tachycardia, without dyspnœa or distress, and little or no benefit accrued to them from training Few of the men of this group became fit from category A, and readmissions to hospital were much more frequent than in the case of other groups Nevertheless, these men had a genuine disability and were not malingerers

The effects of strain —In only a few cases was strain the dominant factor, and even in them there was no certainty of the heart having been altogether normal prior to the stress The men's ages varied from 20 to 40 Six had indulged in strenuous pursuits two were sprinters, two bakers, one a rower All had been remarkably free from infection, and in all but two the symptoms arose after a definite effort greater than had been customary In about one third of the cases the heart was slightly enlarged, in two the cardiac impulse was forcible, soft systolic murmurs were common The average pulse rate was nearer 90 than 80 effort induced marked acceleration, but the period of decline was, as a rule, normal or only slightly lengthened Of 17 cases specially noted, 12 were discharged to category A, 5 to category B I

The immature or untrained heart —The average age of the men in this group was below 19, and the weight was below normal The men's habits in civil life had usually been sedentary, and in the army they had been employed as mess waiters, officers' servants, cooks, or clerks, and had not presented symptoms until undergoing the unwonted strain of marching In response to training improvement was slow but usually satisfactory, about 60 per cent of these men were discharged to category A

Extrasystoles were noted in 59 (6 6 per cent) of 896 cases The extrasystoles were usually single, occasionally multiple The ætiological factor was anæmia, probably toxic, in 11, arterio sclerosis in 7, mitral stenosis in 6, mitral incompetence in 5, recent tonsillitis in 5, rheumatic fever, diphtheria, dysentery (each) in 4, dilatation of the heart, neurosis (each) in 3, gas poisoning and rheumatic fever, scarlet fever, enteric, pneumonia, malaria P U O (each) in 1. In 17 of the 59 cases there were signs of organic valvular disease

Disposal

Of 2156 men whose ultimate disposal was known, 68 (3 1 per cent) were invalided home, 5 died All cases of aortic incompetence and of myocardial degeneration were invalided Men who were fit only for category B III were discharged to sedentary duties In 1917 18 1990 men of all categories were transferred from hospital to depôt, and 69 per cent of these were ultimately discharged to category A In 1917 we had 1283 men under our care 695 (54 per cent) were discharged as category A, 103 (8 per cent) as "temporary base, 115 (8 9 per cent) as B I, 126 (9 8 per cent) as B II, 168 (13 per cent) as B III, 16 (1 2 per cent) as category D (duty in command depôt), 34 were invalided home, 2 died, and 24 were transferred to other hospitals in Egypt In 1918, when the required standard of fitness was certainly not lower than that demanded in 1917, our statistics show a higher percentage of return to full duty. 906 men were transferred to the command depot: 773 belonged to category A, 57 to B I., 58 to B II., 18 to B III. These 906 men were disposed of as follows: To category A, 672; to B I., 119; to B II., 91; to B III., 24. Thus of 906 men of all categories transferred from hospital to command depôt 74·4 per cent., and of 773 men of category A 86·9 per cent., were discharged to category A. These figures illustrate the great value of the training in a command depôt.

In 1917 the disposal of 500 men transferred from hospital to a convalescent depôt was specially analysed by one of us (A. L. K.); 340 cases of D.A.H., 180 of the type-general and 160 of the type-cardiac, were reviewed. Of the type-general 80 (44 per cent.) were discharged as category A, 21 as temporary base, 21 as B I., 51 as B II., and 7 as B III. Thus 32 per cent. were discharged to the two lower grades of category B. In the type-cardiac the results were better, 93 (58 per cent.) being discharged as category A, 21 as temporary base, 14 as B I., 26 as B II., and 6 as B III. Consequently, only 18 per cent. were discharged to B II. and B III. In D.A.H. of the type-cardiac the beneficial effects of graduated training were most evident. We often noticed that a man who laboured under discomfort at the beginning of the morning exercises finished comparatively fresh. Progress was, on the whole, more satisfactory than in the type-general, for the percentage of men who attained category A was 58 in the type-cardiac and 44 in the type-general.

In 92 cases of this series of 500 there was organic disease of the heart or arterial sclerosis; 43 (45 per cent.) were also affected with D.A.H. of infective or toxic origin. Of 16 cases of myocardial disease, with a history of recently superadded infection, 7 became fit for B II. and 9 for B III. category; whereas of 12 myocardial cases with a history of long-standing disability but no recent infection, 2 became fit for B I., 8 for B II., and 2 for B III. category. This group also contained 47 cases of valvular disease, practically all being mitral incompetence. Nineteen of these men gave a history of recently superadded infection, and their disposal was: Category A, 3 (15·7 per cent.); temporary base, 1; B II., 13; B III., 2. Thus 79 per cent. attained only B II. or B III. standard. The remaining 28 cases of V.D.H. were of old standing and without any recent infection. Their disposal was: Category A, 6 (21·5 per cent.); B I., 5; B II., 12; B III., 5. Considering the V.D.H. group as a whole, we are forced to recognise the frequent limitation of response to sustained effort. Few of the men attained category A, but the vast majority became fit for B II. or B III. categories.

In 130 men of the series of 500 there was a rheumatic history. Their disposal was as follows: Category A, 34 (26·1 per cent.); temporary base, 10 (7·6 per cent.); B I., 19 (14·6 per cent.); B II., 52 (40 per cent.); B III., 15 (10·7 per cent.). Whereas 42·4 per cent. of the series of 500 were discharged to category A, only 26·1 per cent. of the rheumatic group became fit for that category. Contrasting 63 cases with a history of rheumatic fever with 67 giving a history of other forms of rheumatic infection (myalgia, chorea, repeated tonsillitis, &c.) 23·8 per cent. of the former returned to category A, and 61·9 per cent. were classified B II. or B III., whereas of the latter 28·3 per cent. returned to category A, and only 41·8 per cent. had to be classified B II. or B III. The disposal of 59 men presenting extrasystoles was as follows:—

Diagnosis.	A.	T.B.	B I.	B II.	B III.	Invalided.	Total
D.A.H.	22	4	1	1	1	5	34
V.D.H.

ACCESSORY FOOD FACTORS (VITAMINES) IN THE FEEDING OF INFANTS.[1]

BY EDWARD MELLANBY, M.A., M.D. CANTAB.,
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF LONDON: HOUSEHOLD AND SOCIAL SCIENCE DEPARTMENT.

IT is obviously a matter of great difficulty for a laboratory worker to open up a discussion concerned with the feeding of children. The task is not rendered easier by my consciousness of the exceptional difficulty in arguing from one species of animal to another when dealing with questions of diet and metabolism. Every worker on the subject of vitamines has this difficulty always before him. We must also recognise that much of the accessory food factor story has not been extended to children or tried beyond the laboratory walls. It is just for these reasons, however, that a discussion in which the laboratory worker and the clinician meet face to face is of great value. The physiologist may throw new light on the points under discussion, and, still more important, the clinician may assist the investigator in evaluating his experimental results and so prevent the exaggeration of one fact at the expense of another.

We have to consider the part played in the nutrition of infants by the three known accessory food factors: (1) antiscorbutic; (2) fat-soluble A; (3) water-soluble B or antineuritic. From the point of view of the children of this country we can probably eliminate the water-soluble B factor. Although infantile beri-beri exists in rice-eating countries, and probably in other places where one-sided and limited diets are in use, the extensive distribution of this factor in food, together with its well-recognised resistance to heat, would appear to make disease due to its deficiency unlikely to occur in Western countries.

Problems Concerning the Antiscorbutic Factor.

Of the antiscorbutic factor I shall say but little. I suggest, however, that there are certain points in connexion with this factor which urgently require consideration. It would be interesting if we could have authoritative statements on the following points: (1) Is the scurvy problem among children of this country one involving real danger? We know that the classical scurvy symptoms are rare, but it is not equally certain that milder symptoms indicating a deficiency short of the production of scurvy are not common. (2) Is it essential that children feeding on dry milk compounds alone should take orange or swede juice?

The second problem involves an answer to two questions: (1) How much of the antiscorbutic factor is destroyed in the drying of milk? (2) How susceptible is the child as compared with the experimental animals? Speaking without any particular knowledge on this point, I should think it probable that, although an infant feeding entirely on whole dried milk may not require extra antiscorbutic, yet when cereals are added to the diet additional antiscorbutic factor will be essential.

---

[1] Opening Remarks at the Discussion at the Section for the Study of Disease in Children of the Royal Society of Medicine on Feb. 27th, 1920 (v. THE LANCET, March 13th, p. 604).

(Continued from previous column.)

For their assistance in the diagnosis, treatment, training, and classification of the patients we desire to express our thanks to R. W. Aitken, J. B. Binns, R. Bruce, W. K. Calwell, H. E. Charles, E. E. Chipp, M. A. Collins, S. J. Fielding, J. K. Lund, S. C. W. Morris, F. J. Pierce, and J. L. Torley.

The Relation between the Fat-soluble A Factor and the Antirachitic Factor.

I propose to deal with what is possibly the fat-soluble A accessory factor. You may remember that the identification of the fat-soluble factor depended on work by Macollum in which the growth of rats was studied. The antirachitic factor, on the other hand, has been so called because of the effect of certain substances in preventing the development of rickets in dogs. Whether they are identical is unsettled, but one point of difference is so striking that it is essential to bear it in mind. The fat-soluble factor is, according to the rat-feeding experiment, absent from all vegetable fats. In the rickets experiments, however, it seems definite that the amount of antirachitic factor is fairly high in some vegetable fats, such, for instance, as peanut, cotton-seed, and coconut oils, and is only present to a small extent in palm-kernel, linseed, and babassu oils.

A second point worthy of emphasis is that fat-soluble A does not appear to be as necessary for growth in the case of puppies as it is in rats. It is true that all the diets of the puppies must have contained a trace of fat-soluble A, but the growth was often just as good when the diet was very deficient in this factor as when containing it in abundance. This fact, previously described by me, has been extended to children recently by Hess and Unger. On a diet of dried separated milk, sugar, cotton-seed oil, autolysed yeast, orange juice, and cereal, sustained over many months, they found the growth of children practically normal. The question arises as to whether, in speaking of the fat-soluble factor in relation to child nutrition, we should still continue to call it a "growth factor." For the growth of puppies and children its influence is probably smaller than that of the other elements of the diet.

It seems most likely that both these differences—that is, (1) the difference in distribution of the fat-soluble factor and the antirachitic accessory factor in vegetable fats; (2) the importance of the fat-soluble factor for the growth of rats and its probable unimportance in the growth per se of puppies and children—can be explained by variations in the general and intermediate metabolism of these animals. These points will, no doubt, be ultimately solved by further experimental work.

In the meantime I would beg those who are extending the results of experimental research on rickets to children not to mix up the two types of work—namely, the growth experiments on rats and the rickets experiments on puppies. In giving cotton-seed oil to children, as recently carried out by Hess and Unger, they had in their minds undoubtedly the generally accepted fact that this oil contained no fat-soluble A. On the other hand, so far as my experiments have shown, cotton-seed oil is to be classed as one of the better vegetable oils in preventing rickets, and, taken in conjunction with the other conditions of diet as described by Hess and Unger, it does not appear to me surprising that rachitic symptoms did not develop. I shall touch again on their experiments later.

From my earlier work, a short account of which has been already published, I consider that it is undoubted that something of the nature of a vitamine, distributed in varying quantities in fats, plays an important part in the development of rickets. I do not wish now to deal further with this particular point. In view, however, of the erroneous and exaggerated views that are widespread as to the action of the antirachitic accessory factor in diet, it is essential that an effort should be made to bring such substances away from their atmosphere of mysticism, and place them side by side with other elements of the diet. If we can in some way link up their action with the known dietetic substances, so that we can discuss them in terms that are familiar, good progress will have been made along these lines. I propose, therefore, in the remaining time at my disposal, to describe some of the more recent results of my experimental work carried out with this end in view.

The Relation of the Antirachitic Factor to Age.

It is a well-recognised clinical fact that active rickets is a rare disease in children over 2 years of age. On the other hand, arguing on the basis of my experimental results obtained with puppies, it is equally certain that, after this age, the diet of a child is often of a more rickets-producing nature—that is to say, it is frequently composed more of bread and other cereals and less of milk. The only deduction that is possible from these facts is that after a time a child becomes more independent, from the rickets point of view, of its diet. I wish to emphasise that it is only the rickets point of view I am discussing. No further deduction from this result must be made as regards resistance to infection or any other pathological condition produced by diet, and more particularly the antirachitic factor of diet at various ages. The fact that the antirachitic accessory factor is of less importance in the older child is also brought out strikingly in puppies. It is obvious for the following well-defined reasons. (1) After the puppy has arrived at a certain age I have been unable to produce rickets by feeding it on rickets-producing diets. (2) On definite diets puppies develop rickets, but if not too severe, and the general condition does not become too bad, recovery at the growing ends of the bones, as indicated by radiographic examination, often takes place, although the animal may remain on the same diet and under the same conditions.

To take the first of these facts, a puppy put on to a rickets-producing diet of separated milk, white bread, meat, orange juice, and linseed oil at the age of 5 months was photographed (Fig. 1) and radiographed (Fig. 3) at the age of 10½ months and was found to be free from rickets. Fig. 2 is a radiogram taken at the age of 5 months, before beginning special diet. The dieting has now been continued over 11 months in all, and the dog is still well and healthy and shows no signs of rickets. The earlier treatment of this particular dog I shall refer to later, when I deal with the effect of exercise and confinement on the development of rickets.

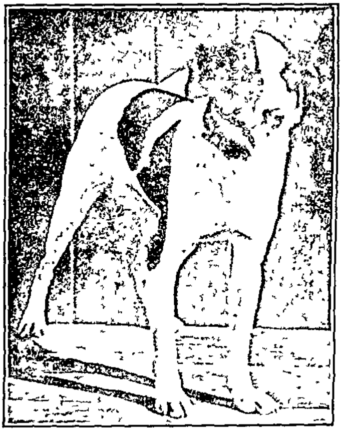

FIG. 1.—Photograph of a puppy, 10½ months old, which has been *on a rickets producing diet for the last five months* without developing rickets.

As regards the second of the above facts, photographs show an instance of self-cure in a puppy when the diet and other conditions were kept as far as possible the same as when the rickets developed. Figs. 4, 5, and 6 represent the changes taking place in the wrist of a puppy. The diet in this case consisted of separated milk, bread, orange juice, yeast, meat, and linseed oil, and you will see that on March 28th, after 3½ months of this diet, rickets had developed. It will be seen, however, from Fig. 5 that, one month after the first radiograph, the healing process had started and renewed calcification is evident between the epiphyses and diaphyses of the distal ends of the radius and ulna. In Fig. 6 the healing process had continued to a further stage. Here, then, we have evidence of a self-curative process taking place in a puppy as it grows older quite comparable to the self-cure which is well recognised as taking place in children.

The above facts can be taken as evidence that the antirachitic accessory factor is more necessary in the diet the younger the animal—that is to say, until some essential process or secretion has developed in the young animal. Until this process has evolved (of its nature I have no idea at the present time) rickets will more readily develop. After the necessary establishment of the new process in the young animal or child, it is a matter of some difficulty to produce rickets. Whether all new calcification processes proceed normally after this event, even in the presence of deficient diets, still remains unknown, but further experiments will soon clear up this point. I should expect that a deficient diet will continue to act in a detrimental way to calcification processes, but possibly not to such a profound extent as in the younger animal and child. It is probable that the legs will continue to bend owing to poor calcification of the periosteal bone of the shafts even after there is good evidence of a healing process going on at the epiphyseal ends. The recovery and calcification of the periosteal bone of the shaft appears to be a much slower process than that at the growing ends.

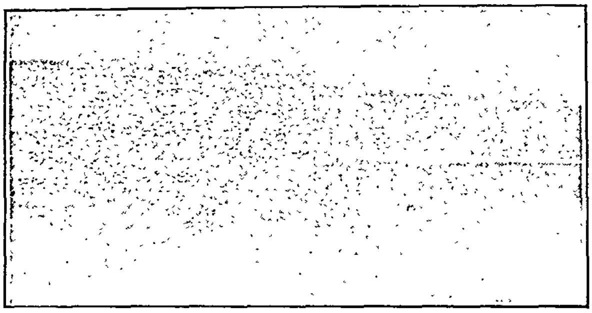

FIG. 2.—Radiogram of puppy in Fig. 1 at the beginning of experimental feeding, showing healthy wrist-joint.

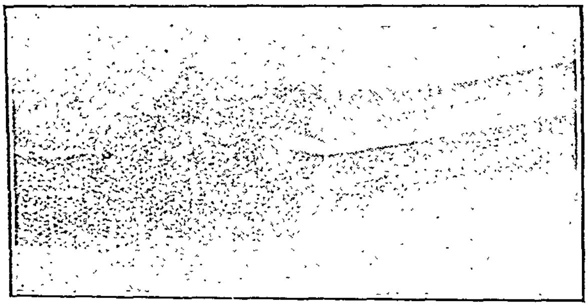

FIG. 3.—Radiogram of puppy in Fig. 1, taken at same time as the photograph, showing healthy wrist-joint.

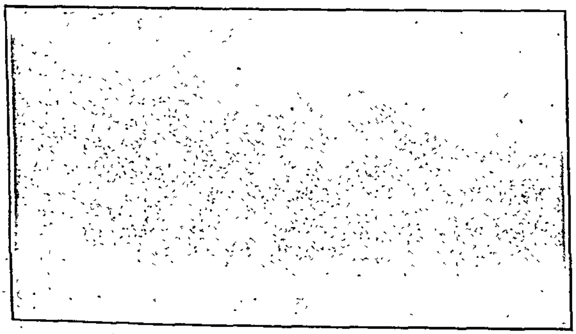

FIG. 4.—Rickets in wrist-joint of a puppy after 3½ months of rickets-producing diet in spite of complete freedom.

The Relation of the Antirachitic Accessory Factor to the Energy-bearing Portions of Diet.

In a paper already published I laid stress on the fact that, although rickets is primarily a deficiency disease of a dietetic nature, other metabolic conditions must obviously be involved, because it is impossible to regard the accessory food factors as independent of the general metabolism and of the other elements of the diet. I emphasised the unity of a perfect diet because we are becoming more and more aware that the removal or deficiency of one element in the diet involves much more than the absence of function or defective function carried out by this one element. It also means that the other parts of the diet cannot do their task efficiently because of the constant interplay between the chemical changes in the body and their dependence on each other. During the past 18 months I have been endeavouring to prove that the same dependence and inter-relationship holds between the vitamines and the proteins, fats and carbohydrates and, although this part of the work is still in progress, sufficient evidence has been obtained to allow the conclusion that their interaction in metabolism is of great importance so far as the development of rickets is concerned. I have explained in my earlier work how the tendency to rickets is increased by more rapid growth, using the weight of the animal as the indication of growth. I am fully aware that increase in weight is not a true indication of rate of growth, because it obviously includes other factors, such as the laying on of fat. For the present, however, I shall confine myself to the relation of the development of rickets to the increase of weight. In many of the experiments the only variable part of the diet was bread, given generally to the animals *ad lib.* Therefore it is evident that, other things being equal, the greater the amount of bread eaten the greater will be the tendency to rickets. This generality is probably true, so long as the increased bread intake results in an increased *storage* of foodstuff, retained by the animal as body tissue. The same condition probably holds with oatmeal and other cereals.

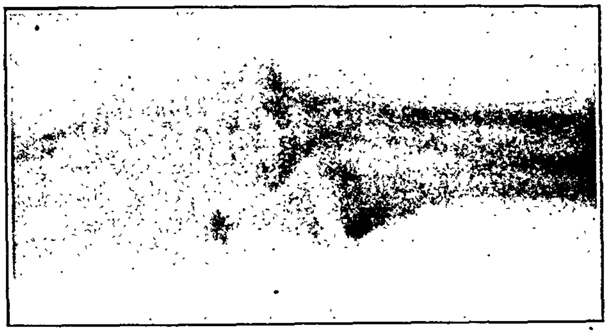

FIG. 5.—Wrist-joint of same puppy as Fig. 4 one month later, undergoing self cure. Puppy on same diet.

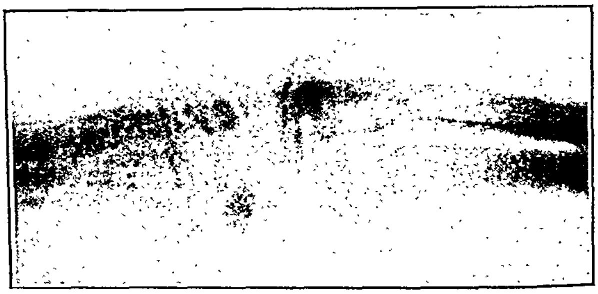

FIG. 6.—Same puppy as Fig. 5 one month later, showing healing process still further advanced.

In order to illustrate this point I shall show you an experiment carried out on three puppies of the same litter. The diet in each case consisted of separated milk, white bread, orange juice, meat, and palm-kernel oil In Fig 7 you see the relative rates of growth of these animals In the course of growth 221, the least rapidly growing, gained 1700 g , 223 gained 2150 g , and 220, the most rapidly growing, gained 2850 g during the same period of 66 days Throughout the experiment, except that the meat was raised from 5 to 10 g per diem a few days earlier in 220 than 223 and 221, the only variable was the amount of bread eaten All other conditions, such as housing, were identical If, therefore, any great difference regarding the development of rickets occurred it can probably be ascribed to the variable bread intake The radiographs of these three puppies after about nine weeks of the diet can be seen in Figs 8, 9, and 10 It will be noticed that 221, the least rapidly growing, has very slight rickets, 220, the most rapidly growing, very severe rachitic changes, and intermediate between these two is 223, whose rate of growth is also midway between 221 and 220 Figs 11, 12, and 13 are photographs of these three puppies, 221 223 and 220 It will be seen that the bending and external appearances of their legs are in keeping with the radiographs of Figs 8, 9, and 10 Let me again repeat that I am only using the word growth in the sense of putting on weight It appears then that puppies, living under similar conditions, show a *greater tendency to develop rickets when the diet contains a larger amount of cereal, all other elements of the diet being kept constant* The question arises as to what special element of the bread is responsible for this greater tendency to rickets This point awaits complete solution, but evidence is accumulating which indicates that the carbohydrate moiety is the offending substance There is some evidence, on the other hand, that protein has an antagonistic action to the development of rickets In my earlier paper I referred to the effect of meat in making a slightly rickets producing diet into a safe one There is also an indication that casein has the same effect F G Hopkins has shown that ordinary commercial casein, as used in these experiments, may have a large amount of fat soluble A accessory factor associated with it Whether, therefore, the protein effect depends on its own action remains to be decided If the antirachitic effect of protein is established we will be able to comprehend one reason why milk is a better preventive of rickets than the corresponding amount of butter I wish to make it clear that increasing the protein alone in the absence of the antirachitic accessory factor does not make a diet safe My view is that it aids the antirachitic vitamine, *so that less of the latter will suffice to keep the growth normal* Carbohydrate, on the contrary, especially when it results in storage of fat, appears to have a decidedly rickets producing effect, and thereby makes additional antirachitic vitamine imperative

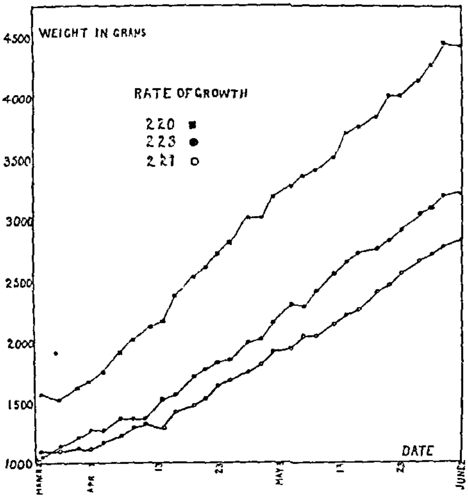

FIG 7—Relative rates of growth of three puppies of the same litter on diets differing only in quantity of bread eaten

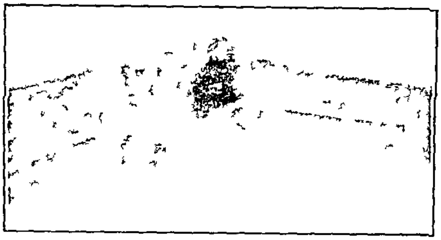

FIG 8 (221) —Very slight rickets only in wrist joint of slow growing puppy (Cf Fig 11)

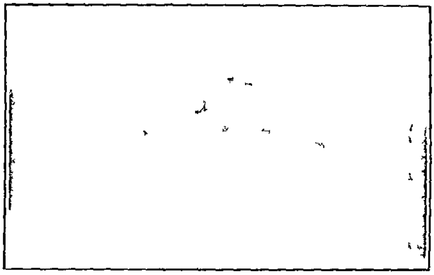

FIG 9 (223) —Rickety changes intermediate in severity between Figs 8 and 10 corresponding to intermediate rate of growth (Cf Fig 12)

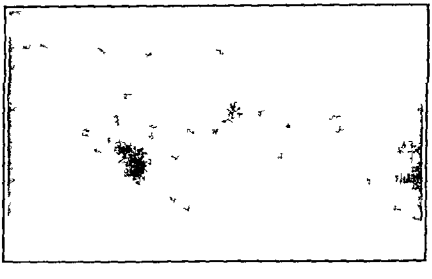

FIG 10 (220) —Severe rickets in wrist joint of most rapidly growing puppy (Cf Fig 13)

It is possible that Hess and Unger s recent feeding experiments on children referred to above, where they found that 180 g of a dried separated milk powder, 30 c cm of cotton seed oil, 30 g of sucrose, 15 c cm of orange juice, and 30 c cm of autolysed yeast, and, later, additional cereal per diem, did not produce rickets, may have as one part of the explanation the high protein intake of these children I have already explained that cotton seed oil is one of the better vegetable oils as regards its antirachitic action in puppies 180 g of a dried separated milk powder must have contained about 65 g of protein, an amount which is abnormally high for children from 5 to 9 months old This high protein intake, together with the antirachitic factor of the cotton seed oil, appear to me to explain satisfactorily the fact that rickets did not develop in these children As regards their observation that the children grew fairly well, in spite of the great deficiency of the fat-soluble accessory factor, this is additional evidence that it is not impossible to argue from my experimental results on puppies to children, as I have previously commented on the good growth that can be obtained in puppies under the same condition.

I should further like to point out that the whole subject of the relationship of accessory food factors to the energy-bearing portion of the diet is one of great importance, and it is necessary that investigations on scurvy and beri-beri should also be undertaken in this connexion. It will be generally agreed that neither scurvy, beri-beri, nor rickets will develop as the result of starvation only. Therefore we must consider whether there is not a positive side also to these dietetic diseases. We know in the case of scurvy and beri-beri that administration of the suitable vitamine will effect a cure, but is it not also probable that the diseases are brought on by some other element of the diet, since they do not develop as the result of starvation? There is some direct evidence that this is the case in avian polyneuritis, and the offending element in the diet is probably carbohydrate. Results tending to prove this have been obtained by Abderhalden, Braddon and Cooper, and Funk. So, also, in the case of rickets, it may be ultimately established that it is excess of carbohydrate in an unbalanced diet which is largely responsible for the development of the disease, and that it is the special function of the antirachitic accessory factor to prevent the abnormality. The fact that the laboratory results obtained on deficiency disease have not been entirely confirmed in practice may be the result of the omission to link up accessory food factors with carbohydrates and the other energy-bearing substances in the diet.

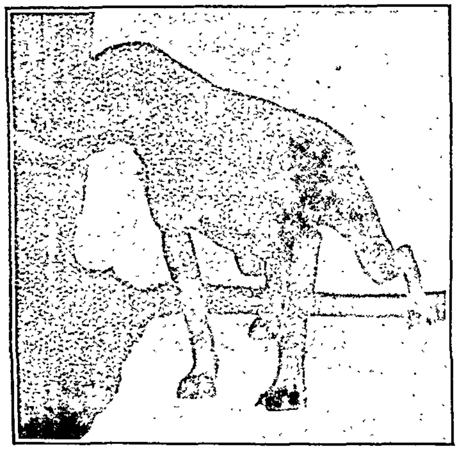

FIG. 11 (221).—Slight rickets. Wrist-joint shown in Fig. 8.

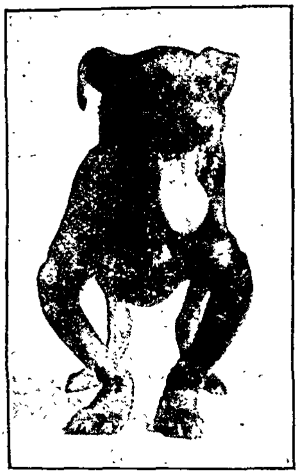

FIG. 12 (223).—Rickets intermediate in severity between Figs. 11 and 13. Joint shown in Fig. 9.

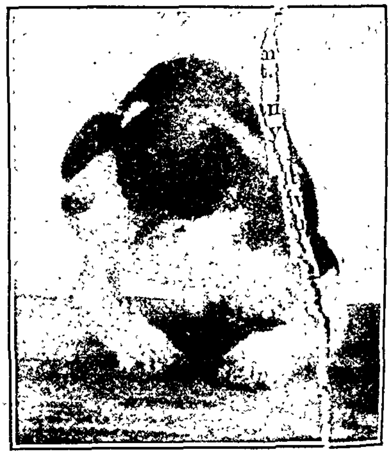

FIG. 13. (220.)—Severe rickets. Joint shown in Fig. 10.

The Effect of Exercise on the Development of Rickets.

I have previously pointed out that, although I considered Finlay's results showing the effect of exercise on rickets to be important, I do not think exercise the prime factor in the ætiology of rickets, but only subsidiary to diet. It is, however, obvious that the ultimate explanation of rickets must embrace this also. Whatever inhibitory effect the constant running about has in the case of puppies, we must, when considering the disease in children, discount a large part of this effect. The reason for this is that rickets develops in many children when only 6 months to 1 year old, and it is difficult to see how running about can play a large part at this age. The exercise obtained by children at this period of their life consists of small movements which make up their general liveliness, and I think it will be agreed that the activity of a child depends, more than anything else, on the adequacy of its diet. Surely the size and number of rooms in the house where the child may carry on its movements are of subsidiary importance to its diet. If exercise and muscular contraction are the explanation of the ætiology of rickets, then there is clearly a simple method of eliminating the disease from Vienna, and the apostles of this gospel ought now to be preaching the glad tidings and observing its effect there. It appears to me absurd to think that the wide-spread and intense nature of rickets in Vienna and elsewhere in recent times has arisen primarily because of any lack of exercise or because of the more defective hygienic conditions that may have developed within the last few years.

My experiments on exercise have been made along various lines and the results obtained may be briefly stated: (1) Confinement on an adequate diet will not produce rickets. (2) Freedom in the daytime will not prevent rickets when the diet is inadequate. (3) Confinement will not prevent the cure of rickets, when the diet is good. On the other hand, complete freedom and the possibility of constant running about, will oppose to some extent the rickets-producing effect of a deficient diet and may carry it over to the safe side in small, slowly-growing dogs.

Fig. 1 is a photograph of a dog previously referred to, which was confined from the second to the fifth month of its life. During this period its diet consisted of 250 c.cm. whole milk, 20 g. meat, 5–10 c.cm. cod-liver oil, 5 c.cm. orange-juice, and white bread. In spite of the absence of the opportunity for exercise, it was a beautiful dog, showing no signs of rickets, as can be seen from the radiograph (Fig. 2) taken after the period of confinement.

The brother of this puppy was allowed complete freedom during the daytime (with a special type of muzzle on) and developed slight rickets, which can be seen in Fig. 4. It was eating a rickets-producing diet during this period, consisting of 175–250 c.cm. separated milk, white bread ad lib., 5–10 g. meat, 10 c.cm. linseed oil, and 5 c.cm. orange-juice. This animal was an instance of self-cure and, while living under the same conditions, calcification of the growing ends of the bones was resumed. This point is seen in the radiographs (Figs. 5 and 6), and has been previously commented on. The rate of growth of this puppy was not very good—it increased 2730 g. in 19 weeks while eating the diet.

Here, then, we have instances of two puppies (terriers), and members of the same family, the one remaining normal in spite of lack of exercise and the other developing rickets with full opportunity for exercise. The dominant factor in each case was the diet. The first dog had an abundance of antirachitic factor in its diet, which included whole milk and cod-liver oil. The second on separated milk and linseed oil was getting little or no antirachitic factor. I wish to repeat, however, that muscular contraction has some inhibitory action on the development of rickets and must be considered in the general scheme.

The points I have discussed, more particularly the relation of the antirachitic accessory factor to the energy-bearing portions of the diet and to exercise, indicate plainly that rickets must be considered as a problem of general metabolism. As a working hypothesis it seems possible to formulate a general scheme in which each of the various elements already discussed can find a place. Any condition which induces a laying on of tissue seems to necessitate a greater intake of antirachitic accessory factor to prevent rickets. On the other hand, conditions which stimulate the metabolism and increase the heat loss relatively to the energy of the stored food work together with the antirachitic accessory factor, and make a less amount necessary for normal growth. For instance, excessive carbohydrates in the diet often brings about a condition of laying on of fat associated with lethargy. Confinement works in the same direction. The diet under these conditions must have more antirachitic accessory factor, otherwise rickets develops. Proteins and exercise, on the other hand, are stimulants to the metabolism, and, when the diet has a relatively high protein content, and the animal is active, less antirachitic accessory factor is necessary.

It is upon this hypothesis that my present investigations on rickets are being continued, and while it is freely admitted that it is not based on complete experimental evidence, a general conception is always useful to an investigator, and can do no harm so long as it is regarded by others in its true light. The generalisation may not explain all conditions under which rickets develops, but we are in the satisfactory position of knowing that its proof or disproof can be easily tested by further experiment.

The Importance of the Antirachitic Accessory Factor in the Feeding of Children.

Up to the present I have dealt entirely with the effect of the antirachitic vitamine in the case of puppies, and it may be of interest to attempt to supply some evidence in support of the animal results, which show that, in the case of children also, this substance is of great importance. I shall deal with two investigations[2] carried out at a time when the presence of the antirachitic accessory factor in food was undreamt of.

In examining school children at Leeds Dr. William Hall was much interested in the great difference in general nutrition, and more especially in the teeth of Jewish and Gentile children, the financial position and housing of whose families were comparable. The results of his investigations were described at a health congress in Leeds in 1902, and his general observations and conclusions are so concordant with my experimental results that I should like to record them. The table here given represents a few of these results.

	Rickets.	Bad or backward teeth.
Good district Gentile school ...	8%	38%
,, ,, Jewish ,, ...	5%	11%
Poor ,, Gentile ,, ...	50%	60%
,, ,, Jewish ,, ...	7%	25%
Country school (Ripon Cathedral School)	11%	33%

The great difference between these two classes of people, more especially in the poor schools, is very striking. It will be further observed that the condition of the poorest Jewish children is better than that of the country children.

Hall then proceeded to investigate the cause of the above-described differences, and finally decided that only the dieting could be held responsible. From his analysis of the diets, which he found very different in the two classes of the community examined, I take the following points: 1. The Jewish families used large quantities of oil in cooking, even in making bread. Fish were generally fried in oil. Potatoes were not boiled in water. If boiled it was usually in milk. Otherwise they were cooked in oil. In making broth, butter and oil were added to it. 2. The normal beverage was cocoa made with milk. This was usually drunk three times a day except on the days when meat was eaten. 3. An analysis of the eggs eaten by the Jewish families showed the large numbers consumed. 4. Fruit and vegetables were used abundantly. 5. The Jewish mothers combined to buy large quantities of the cheaper fish in the market. Herrings were commonly eaten.

Dr. Hall's conclusions as to the inferior physique of the Gentile families were (1) that it did not depend on heredity or on city life; (2) that it was purely dietetic. My researches on animals are in complete agreement with the outcome of these investigations. The diet is certainly the key to the physical defects so common among urban and city inhabitants. It is also remarkable how closely the diets of the Jewish community as observed by Hall follow the animal experimental results. Nearly all the substances mentioned by Hall contain an abundance of antirachitic accessory factor.

The next subject connected with diet and child nutrition to which I wish to refer concerns the inhabitants of the Island of Lewis in the Hebrides. The facts I shall mention are taken from the Carnegie Report of the Physical Welfare of Mothers and Children of Scotland. Many of the inhabitants of these islands live in what are called "black houses." A photograph of a typical "black house" is shown in Fig. 14. They are constructed of turf and stones with a thatched roof. There is often no chimney to the house, and since the peat fires are kept constantly burning and there is no exit for smoke except through the door, the condition of the atmosphere of the house can be well imagined. The walls are often as much as 5 feet thick. Cattle often live under the same roof, the byre adjoining the house, and it is sometimes necessary to pass through the byre to enter or leave the building. Chickens have full run of the house and go on to the beds, tables, and dressers. Altogether the hygienic conditions are dreadful. What about the children? The statements are made in the report: "The children are not taken out until they can walk"; "never taken out until they can walk, except possibly for a few minutes on a fine day in the summer time." It is quite clear, therefore, that, if bad hygiene and lack of exercise are responsible for rickets and ill-health, then the infants of Lewis ought to succumb at a great rate. What are the facts? The main fact is that the death-rate of these infants under 1 year is about the lowest in the British Isles, and has occasionally fallen to as low a figure as 40 per 1000. This death-rate compares very favourably with the infantile mortality of 100 to 300 per 1000 usually found in the towns of this country, in spite of the efforts made to improve the general hygiene. It is remarked that rickets is almost unknown in the island, and "the most striking fact in the adult population is

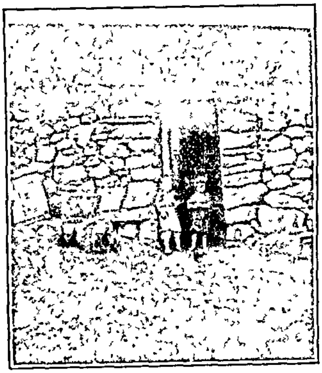

FIG. 14.—A typical "black house," Island of Lewis, in the Hebrides. The sanitary conditions are very bad, but rickets is almost unknown in the island. Note smoke of peat fire issuing from door.

---

[2] These instances were kindly brought to my notice by Dr. H. Scurfield, medical officer of health for Sheffield.

their beautiful teeth—a testimony to the absence of rickets in infancy." Parenthetically, I regret that lack of time has prevented me from showing on the lantern some of the beautiful specimens of my wife's work on teeth—work that has shown that the formation of perfect and imperfect teeth and jaws is affected by diet in a similar way to the development of the normal and rachitic condition of bones.

If we now examine the diet of these people we find results in close agreement with expectations based on the above described experimental work on puppies. In the first place, practically all the children are breastfed. Again, an analysis of the foods eaten shows that the staple articles of diet are fish, oatmeal, and eggs. It is true that milk is scarce, except in the summer, but against this we have breast-feeding affording the opportunity to children to get milk at the most important period of their lives. As regards fish, we find that the liver of fish—that is, the best source of the antirachitic accessory factor—is regarded as the favourite dish. It is described as being mixed with oatmeal and milk and cooked in cods' heads, each member of the family being provided with a cod's head. It is almost certain that the breast-feeding of the children, together with the high protein and antirachitic accessory factor content of the adult diet, are responsible for the absence of rickets, the formation of beautiful teeth, and the very low infant mortality found in these islands, and that this is the case in spite of the dreadful hygienic condition of many of the houses. For the benefit of those interested in the antiscorbutic factor I may mention that vegetables are almost unknown in these parts.

Evidence is accumulating from various sources showing the effect of the diet of the mother on the accessory food factor content of milk, so that it is likely that the milk of the Lewis women is particularly rich in the antirachitic accessory factor. I do not wish, however, to discuss this point now.

If we follow up the mortality and health history of the Lewis children after the age of 1, additional facts of importance can be observed. From 1 to 5 the death-rate among the children is high, when considered in relation to the infantile mortality under 1. The housing conditions are such that epidemics spread rapidly and fatally, and phthisis in 1914 caused a death-rate double that on the mainland. When the children begin to go to school they fall off rapidly until they attain an age when they can look after themselves. This is because they generally have to go to school before their parents are out of bed, and so often do not get a real meal until midday. When the children have arrived at the age when they can fend for themselves and satisfy their appetite by seizing food, if need be, they develop well and ultimately become the fine stock so well recognised as coming from these islands.

The Relative Importance of Diet and Housing at Different Ages.

I have dwelt on this particular point because it seems to afford an opportunity of realising to some extent the relative importance of diet and housing at the different ages. It is difficult to avoid the conclusion that diet is everything to infants under 1, and so long as this is good, bad hygienic conditions are of small significance. After the first year, however, when the child becomes more susceptible to measles, bronchopneumonia, and other infections, then clearly the housing and hygienic factors, in addition to the diet, are of great importance. If these suggestions could be definitely proved and accepted, we should have gone a long way towards the solution of the problem of race decadence. It is reasonable to accept as facts that where there is low infant mortality there is an almost complete absence of rickets and the teeth of the people are good. Also that the production of rickets depends on a *relative* insufficiency in the diet of the antirachitic accessory factor, the best sources of which are fish oils, animal fats except lard, milk, and eggs. It is also probable that anything which stimulates metabolism, such as high protein in the diet and exercise, aids the antirachitic accessory factor; while excess of carbohydrate, especially if it leads to a laying on of fat, works in an antagonistic way to the vitamine and makes it necessary to have a greater amount in the diet to ensure normal growth of bone, formation of sound teeth and jaws, and good general health.

My investigation on rickets is still in progress and the results remain incomplete. The mode of production of the disease is obviously complex, otherwise it would have long been solved; but by considering and altering each factor in turn the animal experimental method will certainly in time clear up all the points of difficulty.

ON THE RELATION OF THE LIPOCHROME PIGMENTS TO THE FAT-SOLUBLE ACCESSORY FOOD FACTOR.

BY O. ROSENHEIM AND J. C. DRUMMOND.

(From the Physiological Laboratory, King's College, London, and the Biochemical Department, Institute of Physiology, University College, London.)

SOME two years ago, when studying the growth-promoting food factor known as fat-soluble A, we were struck by the similarity of the distribution of this important dietary constituent to that of fat-soluble or lipochrome pigments. Accordingly, we carried out a number of experiments in order to ascertain whether the accessory substance is related to, or identical with, a member of the class of pigments which are found in association with fats.

The chief lipochromes* which have so far been identified and isolated as well-crystallised substances are carrotene, $C_{40}H_{56}$ (from carrots, green leaves, milk-fat and corpus luteum), and its isomer lycopin (from tomatoes), xanthophyll, $C_{40}H_{56}O_2$ (from leaves), and its isomer lutein (from egg-yolk), and, finally, fucoxanthin, $C_{40}H_{56}O_6$ (from brown algæ). All lipochromes are characterised by their extreme lability and power to take up oxygen. The hydrocarbon carrotene, for example, is able to take up 500 times its own volume of oxygen, and on this account the important function of a respiratory pigment has been ascribed to it by botanists. It is certainly significant that carrotene occurs always together with its oxide xanthophyll in the chloroplasts of green leaves, where it is associated with chlorophyll. The lipochromes are also of frequent occurrence in lower plants and bacteria. The animal organism appears to be unable to synthesise these substances and depends on plant products for their supply. It is significant from our point of view to find that their occurrence in the animal body is most obvious in those organs and secretions which are connected with reproduction and the nutrition of the growing young (ovaries, egg, milk).

The Origin and Occurrence of Lipochromes in the Human Body.

Largely as a result of the painstaking researches of Palmer and Eccles[1] in America, we possess to-day much interesting information regarding the origin and the occurrence of these pigments in the animal body. These authors have demonstrated in a most striking manner how the colour of body-fat, milk-fat, or egg-yolk is derived from the lipochrome pigments ingested in the diet. Thus, the normal yellow colour of butter is due to carrotene and xanthophyll derived from the grass and roots consumed by the cow. Should the source of pigments be cut off, as, for example, by maintaining the animal on a diet of bleached hay and white corn, the butter-fat becomes progressively paler until it is practically white. That the fat does not lose its colour at once is attributed to a gradual utilisation of the reserves of pigments which are contained in the animal's body. Consequently, should cows be deprived of an adequate supply of the pigments in their diet, those whose body-fat is deeply pigmented with lipochromes, such, for example, as animals of the Jersey breed, will be able to provide a coloured milk for a longer period than those whose reserves of pigment are much smaller.

---

* Thudichum (1869) was the first to recognise the near relationship of the yellow animal pigments (of egg-yolk, ovaries, blood serum, and milk-fat) to those of plants (of carrots, certain fruits, and flowers). He introduced the name "lutein" as a group name, which was later on changed into "lipochrome," and quite recently into "carotinoid." Since the name "lutein" has now been reserved for the yellow pigment of egg-yolk, and as "carotinoid" does not express the intimate association of these pigments with fats, we propose to retain the term "lipochrome," which is now well established in physiological literature. In accordance with the nomenclature adopted by the Chemical Society, the term "carrotene," indicating the hydrocarbon nature of the substance, is used in preference to "carotin."

If we consider other examples of the mobilisation of reserve substances which occur in the animal body, it will be found that such processes are of a protective nature, and are called into play when an important function is in danger of being stopped owing to a deficiency arising in the normal supply of a necessary substance. A good example of this may be seen in the protein metabolism of the lactating female. To ensure the survival of the species it is of fundamental importance that the nutrition of the young during the period of dependence on the mother shall be adequately provided for, even if the results are for the time being detrimental to the parent. When a lactating mammal is unable to obtain a sufficient amount of protein in her diet to provide material for the normal synthesis of the milk proteins she draws upon her own tissues to make good the deficiency, and will continue to secrete a milk normal as regards its protein content as long as this endogenous source will permit. Naturally, if the deficiency in the diet of the mother continues, sooner or later even this source will fail, and the nutrition of the suckling will be impaired. The process is, however, one which protects the young against temporary fluctuations in the nutritive value of its food. A similar mechanism has been elaborated in the animal organism for ensuring the presence of lipochromes in milk and egg-yolk when the diet of the female is one deficient in this respect; a fact which strongly suggests that the lipochromes play an important rôle in the nutrition of the young. That there is a similar protective mechanism which is concerned with providing the young with a supply of the fat-soluble accessory factor when the diet of the mother is deficient in that substance is already known.[2] [3]

Correlation between the Distribution of Fat-soluble A and the Lipochromes.

Apart from these interesting facts, we were impressed by the correlation of the distribution of the fat-soluble accessory substance and the lipochromes. This is illustrated by Table I., which contains a few of the chief examples. These observations led us to make a study of the functions of the lipochromes in nutrition and growth, and although our experiments are far from being complete, owing largely to an interruption of several months' duration, we desire to contribute this note in order to outline the results which we have obtained up to the present time.

TABLE I.—*Showing Distribution of Lipochromes and Fat-soluble A.*

* Carrotene and xanthophyll and possibly other unknown pigments.

Dietary Experiments with Carrotene.

We first directed our attention to carrots, as being a foodstuff rich in the lipochrome carrotene, and we naturally ascertained first whether this root contains the fat-soluble vitamine. Although we obtained evidence that the accessory factor is present in carrots, our experiments with rats did not indicate that this vegetable is a particularly rich source of that substance. Denton and Kohman[4] have since found appreciable amounts of fat-soluble A in carrots. The drying of carrots appeared to cause a loss of the accessory substance; at any rate, a sample of commercial dried carrots was less efficient as a source of this dietary component than the fresh roots which we tested. Green vegetables, in which xanthophyll is in excess of carrotene, were found to be considerably richer in the fat-soluble factor than carrots.

The results were sufficiently conclusive to encourage us to test the pigments themselves, and accordingly pure crystalline carrotene was prepared from carrots. The first preparation obtained by the usual process was tested on young rats which had been fed on a basal diet free from the fat-soluble factor, until they began to decline in weight. As has already been reported[5] no recovery of health or renewal of growth followed this addition to the diet. In view of the labile nature both of carrotene and the fat-soluble substance, a further preparation of the pigment was made in a pure condition, great care being taken to prevent oxidation or exposure to high temperature. This specimen was also found to be without growth-promoting action.

When we tested the crude carrotene fraction, which contained other substances, such as xanthophyll and cholesterol, we observed definite evidence that the fat-soluble substance was present, although in low concentration. We were not successful in preparing crystalline xanthophyll from the crude carrotene fraction, this not being a very suitable source. A crude xanthophyll preparation which was tested gave inconclusive results, there being a slight indication of growth-promoting powers.

These results weakened somewhat our conception of the identity of the fat-soluble factor with a lipochrome pigment; nevertheless, we turned our attention to the study of certain animal oils and fats which are known to contain both lipochromes and the growth-stimulating factor.

Dietary Experiments with Unsaponifiable Fractions of Animal Fats.

The lipochromes which accompany many fats are generally supposed to be resistant to the action of alkalis, and may be detected in the unsaponifiable fraction, but certain facts indicate that the process of saponification is not without action on the pigments. A number of oils and fats rich in the fat-soluble A were hydrolysed by alkalis, by a method which eliminated as far as possible the risk of changes resulting from oxidation or exposure to high temperatures. From the saponified oils the unsaponifiable fractions were separated, and tested for the presence of lipochromes by the usual chemical tests, and for the presence of the fat-soluble vitamine by feeding experiments with rats. In this manner the unsaponifiable matter of butter-fat, cod-liver oil, liver tissue, whale oil, and shark-liver oil was prepared and tested. These fractions all gave reactions for the lipochrome pigments, but, as has been already reported,[5] they were found to be valueless as source of the accessory substance. It must, however, be remembered that the lipochromes are highly labile compounds and easily undergo decomposition during their preparation under the influence of air and light. In this respect also they resemble the fat-soluble vitamine. (See Zilva[6] and Osborne and Mendel.[7])

Possibility of Relationship between Lipochromes and Fat-soluble A.

It seems, however, justifiable to conclude from our experiments that, at any rate, the pigments present in our extracts, as well as crystalline carrotene, are not identical with fat-soluble A. In spite of these negative results, we still feel that the possibility of an intimate relationship existing between the lipochrome pigments and the fat-soluble accessory substance should be carefully considered. In this connexion it is well to bear in mind that the lipochromes exist in plants and animals in close combination with other substances. Thus it would seem that the lipochromes of flowers and fruits are present in some combination with cholesterol esters of fatty acids. (See Czapek, "Biochemie der Pflanzen," 1905.) One of us found some years ago that the lipochrome of ox-serum may be obtained in watery solution, combined with alkaline metaprotein and cholesterol esters, on coagulating the serum proteins without the addition of acids. From this combination the pigment is liberated by boiling alcohol. Further, Palmer and Eccles[1] describe the pigment carrotene existing and being transported in the blood in the form of a water-soluble complex with protein. This complex is a fairly stable one, but is readily broken down by the action of alcohol, after which the pigment is soluble in the usual fat solvents. Now McCollum, Simmonds, and Pitz have shown that fat-soluble A occurs in the embryo of certain seeds in a form which is insoluble in fat solvents, and they suggest that this form is probably a complex of the accessory factor with another cell-constituent, such as protein.[8] Whatever the nature of the complex may be, it is one which is broken down by treatment with alcohol, the fat-soluble substance being liberated in a form soluble in fat solvents.

Palmer and Kempster[9 10] have recently investigated whether or not the lipochromes are of importance to the fowl for growth, fecundity, or reproduction. From a number of observations on chickens, fed on diets supposedly free from lipochromes, they conclude that it is possible to raise fowls to maturity on rations containing the merest traces of, if not entirely free from, these pigments, and that the full-grown hens in such cases show normal fecundity. No abnormality of the lipochrome free eggs was noted.

Experimental Evidence Reviewed.

A closer examination of their experiments, however, reveals the fact that when the birds were fed solely on a diet of white corn, bleached flour, and separator milk, a diet which the authors considered practically free from lipochromes, and which would also be very deficient in fat-soluble A, they were unable to develop normally, and it was found necessary to add a ration of pig's liver before satisfactory growth was observed. Apparently the authors regard this supplement as being free from lipochrome pigments. Certain of our experiments have shown us, however, that substances resembling the lipochromes do occur in pig's liver, as well as in the livers of all species as yet examined. Consequently it is quite possible that the supplement of liver was actually providing the lacking pigment ubstance conceivably required for normal development. In fact, it is not unreasonable to interpret certain results which these American workers have obtained as evidence in support of the idea that substances closely related to the lipochromes are of mportance in nutrition. For instance, their experiments show that when a fowl is given a diet deficient in these pigment substances, she gradually oses the deposits which are present in many of her own tissues, particularly if she is laying at the time. When these reserves are nearly exhausted, as is indicated by the pallor of the shanks and beak, and a diet rich in xanthophyll is administered, the ngested pigment is all deflected to the ovaries and used for inclusion in the yolks of the eggs which are being formed, none being incorporated in the adipose or other fatty tissue as long as fecundity lasts. In fact, the authors state their belief that the fading of the normal colour of the ear lobes, beak, and shanks which occurs during fecundity is due to a deflection of the normal path of excretion of xanthophyll from those parts to the egg-yolk. It appears reasonable to argue that such deflection would not occur unless the substances were required for a definite and important function in the egg. That the eggs laid by the fowls on the supposedly lipochrome-free diet were found to be fertile is not a strong argument in support of the dispensability of the pigments, for it is recorded that the yolks of these eggs retained a certain amount of residual colour, although Palmer and Kempster do not believe this was due to carrotene or xanthophyll. Only those who have had extensive experience with feeding experiments can fully appreciate how very small are the traces of certain dietary constituents which are sufficient to provide what the animal body requires for its growth.

Particularly in the light of the recent work by Steenbock and Boutwell[11] does it appear unlikely that the association of yellow pigments with growth-promoting properties ascribed to fat-soluble A is mere coincidence.

These authors have also commented on the existence of this association in a number of types of maize, and their interesting results are given in Table II.:—

TABLE II.

—	Value as source of fat-soluble A.	Pigments.
Yellow maize	+	+
White maize...	—	—
Red maize (yellow endosperm) ...	+	+
" " (white ") ...	—	—
Potato	—	—
Yellow sweet potato	+	+

Further Experiments.

Since our own work has led us to the view that the fat-soluble A is probably not identical with either carrotene or xanthophyll as such, but that it is in some manner associated with this type of pigment, we have extended our investigations to the pigments of liver-fats. These results will be published in full at a later date, but it may be stated that we have found in liver tissue, besides carrotene and xanthophyll, a substance which gives certain reactions similar to those given by the lipochromes, and which is not identical with any known member of that class. This substance appears to be responsible for the well-known colour-test with sulphuric acid, which is extensively employed by analysts as a test for cod-liver oil. The opinion regarding this test seems to have been that it was due to an impurity derived from changes of a putrefactive nature in the livers during the preparation of the oil, and that it would not be given by a good sample prepared from the fresh organ. We believe we have sufficient evidence to say that this view is incorrect, and that the substance is a normal constituent, not only of fresh cod liver, but of all liver fats. It remains in the unsaponifiable residue of liver oils, is very prone to oxidative changes, and appears to be derived from the food. Attempts are being made to isolate the substance and to identify its character, it being of particular interest to us to ascertain whether it is another lipochrome.

Conclusion.

In summarising our results, so far obtained, it may be said that, whilst the identity of the fat-soluble accessory food factor with a known lipochrome pigment appears to be improbable, there are reasons for assuming that it is in some manner associated with that class of substances.

BRISTOL HOSPITAL SUNDAY FUND.—Up to the present £5039 have been received as the result of the Hospital Sunday collections in Bristol, and it is practically certain that the total for 1920 will be a record amount.

TREATMENT OF BILHARZIA DISEASE WITH TARTAR EMETIC IN SOUTH AFRICA.

BY F. G. CAWSTON, M.D. CANTAB ,
FIRST STREATFEILD RESEARCH SCHOLAR, ROYAL COLLEGES OF PHYSICIANS AND SURGEONS

THE treatment of bilharziasis in South Africa of 30 cases varying from 9 to 39 years of age, with symptoms lasting from one week to 25 years, helps to confirm the value of intravenous injections of a solution of antimonium tartrate. As far as the *destruction of the parasites themselves* are concerned this drug would appear to be equally effective in recent and in long-standing cases; whilst the effect of the drug on the parasites in the blood-stream would appear to be in no way related to the age of the patient.

The experience I have gained from carefully watching a series of cases during the last 12 months leads me to say that —1. The scalding and vesical pain that these patients complain of may be expected to disappear after the second or third intravenous injection. 2. The patient will probably remark on the disappearance of the blood from the urine within a week or ten days, though hæmaturia may be prolonged where there is a tendency to papillomatous growths. 3. Degenerating miracidia may be seen within the shells of the eggs shortly after the dose administered has reached a full grain. 4. That blackened eggs may appear after a total of only 1 1/4 gr. has been given. 5. Free swimming, dying miracidia are not uncommon in undiluted urine at the end of two weeks' treatment. 6. A cloudy condition of the urine due to phosphates is common during the second or third week, and readily responds to cystopurin. 7. The disease is usually cured when the urine has been free from living eggs for a fortnight or three weeks. 8. The presence of many dead eggs and blood cells indicates that further treatment is required. 9. The absence of living eggs for a month indicates that the female parasites are all dead. If the parasites are going to cause mischief again they are unlikely to take more than a fortnight to three weeks to recover after the administration of the drug has ceased.

Certain Cases Described.

Case 1 is an example of the occurrence of pain after a concentrated solution. G. R. R. contracted bilharzia disease at Clairwood six years ago. On Oct. 8th the urine was blood-stained and contained terminal-spined ova. He was given tartar emetic ¼ gr. intravenously. On the 10th he received ½ gr., on the 14th ¾ gr., and on the 21st 1 gr. After this last injection he complained of some pain in the shoulders lasting two days. Examination of the centrifugalised deposit from the urine on Nov. 21st showed fewer ova, half of which were black or shrivelled and the urine itself was clearer. On the 27th he reported that no blood had been seen since the 23rd. He received 1 gr. tartar emetic in 2 c cm. of distilled water. On the 30th he again complained of pain in the shoulders, lasting two days, after a second injection of 1 gr. in 2 c.cm. of water. On Nov. 5th he received 1¼ gr. tartar emetic in 5 c.cm. of distilled water without any after pains. No ova could be detected on five separate occasions after this, but one degenerated miracidium was seen just moving in the undiluted urine on the 13th. On Dec. 4th he was discharged as cured, having received 10¾ gr. of tartar emetic solution, the urine being free for over a month from all ova, except the miracidium mentioned above. In this case the solution was used on several occasions twice as strong as what I usually inject.

On Feb. 4th the patient returned complaining of acute cystitis. The urine was cloudy and contained mucous membrane cells but no ova. However ½ gr. tartar emetic was given intravenously and ¾ gr. on the following day. This latter dose was followed by a slight rigor an hour later. On the 7th 1 gr tartar emetic was given, but the urine was still free from ova, suggesting that the parasites had all been killed in November, and the cystitis was not due to any recurrence of bilharzia infection

Case 2 records vomiting in a child after injection. C. R. contracted bilharzia disease through bathing in the Umhlatazana at Clairwood two years ago. He is now aged 13. On Nov. 5th the urine was blood-stained and contained numerous terminal-spined ova On the 7th he received ¼ gr. tartar emetic intravenously. On the 10th he received ⅜ gr. and on the 12th ½ gr without ill effects. After receiving 3⅞ gr in all by the 22nd, the centrifugalised urine showed debris and three dead eggs. On three occasions this patient vomited after an intravenous injection of a full grain, which was given shortly after a light meal. On Dec 13th he was discharged as cured, having received 9½ gr of tartar emetic intravenously. Repeated microscopic examination of the centrifugalised urine showing only dead ova since Nov. 22nd and the urine remaining clear.

Case 3 records a rigor in a child following injection. H. R, aged 9, contracted bilharzia disease through bathing in the Umhlatazana at Clairwood two years ago. I have obtained numerous *Physopsis africana* from this river. On Oct. 9th the urine was very cloudy and contained numerous ova and blood cells From Nov. 5th to 14th he had four intravenous injections of tartar emetic, commencing with ⅜ gr. On the 15th the urine was clearer, this might be due to cystopurin which he was taking, but the ova were blackened from the action of antimony On the 17th he received ½ c cm. of collosol antimonium (Crookes). The temperature rose to 99·8°F. the following day, though the patient was put to bed immediately after each injection. On the 20th he received 1 c.cm. also intramuscularly and on the 25th ¾ c cm. with similar rises in temperature On the 27th and 29th he received ¾ gr. tartar emetic intravenously. On Dec. 2nd a full grain of the drug was followed by a rigor half an hour after the intravenous injection. The following day the urine was very clear and contained only a few dead ova. On the 4th, 6th, 8th, and 10th he received intravenous injections, a full grain on the 8th without bad effect. On the 13th he was discharged as cured, as five microscopic examinations of the centrifugalised urine revealed nothing but dead ova. He received 6$\frac{5}{16}$ gr. of tartar emetic intravenously and 2¼ c.cm. of collosol antimonium.

Case 4 is one in which a measly rash followed injection. M. M. contracted bilharzia disease 12 years ago from the river at Amersfoort, which is a tributary of the Vaal. He had noticed blood in the urine practically every day since then, and occasionally suffered from such acute attacks of renal colic that hypodermic injections of morphia were necessary. Micturition was always attended by a scalding sensation. Nov. 11th. Cloudy urine contains numerous terminal spined ova and numerous cells. 12th: Tartar emetic, ¼ gr. intravenously. 14th. Tartar emetic, ½ gr.; slight vomit. 16th: Tartar emetic, ¾ gr., all right, slight blister from the 12th, urine contains ova and cells. 18th: Tartic emetic, 1 gr.; slight vomit; measly rash all over; blisters along veins of arm injected Sod. sal, 8 gr., sod. bicarb., 8 gr., tr. nuc. vom., m viii., t.d.s., corrosive sublimate lotion, codeia, ½ gr. at night. 21st. Tartar emetic, 1¼ gr.; vomit and cough; skin almost normal. 23rd: Tartar emetic, 1¼ gr., one hour after codeia, ½ gr; slight vomit and cough, skin normal. 24th: Skin normal 25th: Tartar emetic, 1¼ gr., three-quarters of an hour after codeia, ½ gr.; urine clearer, does not scald 27th: Tartar emetic, 1¼ gr., half hour after codeia, ½ gr.; no cough or vomit; urine contains ova. Dec. 1st: Tartar emetic, ⅞ gr.; urine clearer than it has been for 12 years. 2nd. Urine contains a few dead ova and dead masses of cells. 3rd. Tartar emetic, 1 gr.; urine contains few dead ova and 1 dead miracidium. 5th Tartar emetic, 1½ gr., slight cough; urine contains very few black ova. 7th: Tartar emetic, 1⅛ gr.; slight vomit; urine contains 2 dead ova. 9th: Tartar emetic, 1¼ gr.; bad cough. 11th: Urine contains no ova; no colic or pyrexia noted throughout. 12th: Tartar emetic, 1 gr.; no cough; 1 dead ovum, 2 dead masses of miracidia. On Feb. 20th the patient reported that there had been no recurrence of blood in the urine.

Case 5 is an example of pyrexia and chronic cough after injection. J. B. contracted bilharzia disease from bathing in the Libode river three years ago. There had been hæmaturia ever since. He is now 10 years old. On Oct. 25th the urine, which was tinged with blood, contained numerous terminal-spined ova and shreds of mucous membrane. He had never suffered pain or colic. On the 27th he was given ♏ v. collosol antimonium intramuscularly; this dose was repeated on the 29th and 31st without ill-effects, and a ½ c.cm. was given on Nov. 3rd with only a slight rise in temperature. On the 5th he commenced intravenous injections of tartar emetic, receiving ⅛ gr. on this date and ¼ gr. on the 7th. On the 10th his temperature rose to 104° F., and was not normal until the 14th, when he received ½ gr. without ill-effect. However, for a fortnight he was troubled with cough, which seemed to be aggravated by the intravenous injections. On the 15th the urine was clear for the first time for about three years and the ova were mostly black. On 12 subsequent days the centrifugalised urine was seen to contain only dead ova, most of which were jet black. On the 20th he received 1 c.cm. collosol antimonium. His temperature rose to 100·4° the following day. On Dec. 18th he was discharged as cured, having received 8½ gr. of tartar emetic intravenously and 2·5 c.cm. of collosol antimonium. On Jan. 21st the father, who is a medical man, reported that there had been no recurrence of hæmaturia, and the microscopic examination of the centrifugalised deposit of his clear urine revealed an entire absence of ova.

In Case 6 the ova were blackened by collosol. H. B., aged 12, contracted bilharzia disease from the Libode river at Libode three years ago, and noticed blood in the urine every day since then. For the last two years he has had occasional attacks of renal colic, usually in the right side, but once in the left. These attacks were bad enough to require hypodermic injections of morphia about once in three months, otherwise he was free from pain. On Oct. 25th the urine was blood stained and contained terminal-spined ova and shreds of mucous membrane. On the 27th ♏ v. of collosol antimonium (Crookes) were injected into the right deltoid muscle. This dose was repeated on the 31st and Nov. 4th. The first dose gave rise to a temperature of 103·5° F., which rose after the second to 101·5°. The third dose was not associated with any rise in temperature. On Nov. 1st the slightly blood-stained urine contained many blackened ova.

In view of the presence of *B. coli* in the urine, cystopurin tablets were given daily, commencing with half a tablet dissolved in water t.d.s. On Nov. 6th intravenous injections of tartar emetic were commenced, ⅛ gr. was given on this date and ¼ gr. on the 7th. There was a slight bronchial cough for the next week or ten days. On the 22nd the patient had a severe attack of renal colic, which necessitated hypodermic injections of morphia ⅛ gr. and later ¼ gr. X ray examination showed no calculus. On the 25th the urine contained numerous phosphates, crystals, leucocytes, and one living miracidium inside a shell in the undiluted specimen. This was the last living ovum to be detected in the urine; from that time most of the ova were blackened. After 1 gr. of tartar emetic solution intravenously on Dec. 2nd the patient had some difficulty in breathing and slight cough for about half an hour. On the 13th ♏ x. of collosol antimonium were given intramuscularly; the temperature rose to 102° F. the following day. On the 18th the patient was discharged as cured, having received 8½ gr. of tartar emetic and ♏ xxv. of collosol antimonium (Crookes). On Jan. 21st the urine was again examined for ova, though there had been no recurrence of his symptoms. Three dead ova were found, one of which was blackened.

Case 7 records headache following injections. J. W., aged 16, had suffered from slight hæmaturia and occasional pains in the back for five years since bathing in the Umhlatazana at Escombe, Natal. He was pale, but there was no tenderness of the internal organs. On Nov. 24th, 1919, the urine was cloudy and the centrifugalised deposit contained shreds of mucous membrane, blood cells, and terminal-spined ova. On the 26th he was given ¼ gr. tartar emetic in 1 c.cm. of distilled water. The skin was sterilised by spirit vini rect., and all the injections were given in the same vein of the right anticubital space. There was no local reaction or general symptoms throughout the treatment except headache. The injection of ½ gr. on the 27th was followed by rather severe headache, which lasted 24 hours. This was relieved by a sod. sal. mixture. On Dec. 1st he said he thought the urine was clearer. He had had ¾ gr. on Nov. 29th, and received a full grain on Dec. 1st. On the 3rd he received 1¼ gr. without ill-effect, a grain on the 5th, and 1¼ gr. on the 8th. On this occasion he felt a slight irritable feeling in the throat, but had no cough or retching. The urine contained several blackened ova and two living ones. These were the last to be seen, and the injections no longer caused headache. On the 13th he said there was no sign of any blood, and the urine was free from ova on this date and the 19th. In all he received 10¼ gr. of tartar emetic. On Jan. 6th the patient still remained free from symptoms, and the clear urine contained only two dead brown eggs.

Case 8 was complicated by "gravel." On Jan. 13th, 1920, A. S., aged 39, reported to me that he had contracted bilharzia disease at Bozana, a tributary of the Umvoti, when 14 years of age. He had noticed a distinct itching of the skin whenever he bathed there. For some years he had had attacks of gravel every four or five months, but this had been relieved since he had undergone treatment by Dr. W. A. Peverley, of Malvern. Eighteen months ago, however, he had had another bad attack of gravel and had suffered on and off since then. He was still complaining of pain in the left side, and, as the typical terminal-spined eggs were found in the urine, he was given ⅜ gr. tartar emetic intravenously at my consulting-room. The following day he received ¾ gr., and was recommended to take sodium phosphate effervescent. One blackened egg was found in the urine on Jan. 19th, after he had been given a total of 3¼ gr. On the 24th 1½ gr. was given without ill-effect. The urine was cloudy with phosphates on the 23rd; but no ova, dead or alive, were detected after Jan. 21st, except on the 31st, when four blackened eggs were seen. On Feb. 2nd he was given his last injection of 1 gr. and was discharged from further treatment. He had received a total of 10⅞ gr. tartar emetic intravenously, and 1 c.cm. collosol manganese intramuscularly to clear up the urinary tract. On the 14th the urine was found to be still free from eggs, but he still had a tendency to gravel formation.

Case 9 showed a tendency to cough after injection. T. G. contracted bilharzia disease through bathing in the Orange River at Upington, Northern C.P., during the recent rebellion. He was treated for it whilst on further service in German West Africa; but had had continuous burning sensation whilst passing his water during the last three years, and this was always worse during the hotter season of the year. He commenced treatment with ¼ gr. of tartar emetic on Jan. 26th, when the blood-stained urine was found to contain numerous terminal-spined eggs. On the 28th, when he returned for his third injection, he stated that the burning sensation had gone. On the 30th the urine was getting clearer and contained fewer eggs. On Feb. 2nd he stated that the urine was decidedly clearer. After 1 gr. tartar emetic on the 5th he was troubled with an irritating cough lasting about three minutes after the injection; this was noticed on five subsequent occasions. Black and dead eggs were discovered in the urine on the 7th, but no eggs after that. On the 11th he stated that there was now no sign of blood and, up to the 19th, the centrifugalised urine showed entire absence of eggs. He has now received 11¼ gr. of tartar emetic, but the injections are being continued.

Remarks on Treatment.

In a warmer climate it would seem that one is justified in treating the majority of bilharzia cases as out-patients, provided they are warned against the very serious risk of contracting a "cold" after an injection, and provided they are in easy reach should any untoward symptoms, such as throbbing in the head, vomiting, and faintness occur. My experience would seem to show further that: 1. It is unnecessary for adults to remain in bed, but that they should stay quietly indoors for the rest of the day following an intravenous injection of antimonium tartrate. Children should be kept in bed for the rest of the day. 2. A rise in temperature is most uncommon, and can usually be explained by local sepsis or exposure to cold shortly after an injection. 3. Many patients show no ill-effects whatever; whilst in others there is a risk of cough, vomiting, tightness in the chest, or syncope immediately following the injection. 4. In codeia we have a valuable means of counteracting these possible reactions to the drug; but it is seldom found to be necessary if only moderate doses have been given. 5. A dose of 1½ gr. is sufficiently large to administer to any patient, and may be repeated every second or third day. 6. ½ gr. is a sufficiently large dose to commence with, and a tolerance, even for this amount of the drug, should sometimes be acquired by previous medication with small intramuscular doses of collosol antimonium. 7. The injections may be given daily until ¾ gr. is tolerated, and then on alternate days or every third day. 8. Where doses not exceeding 1½ gr. are given regularly for three weeks to a month a total of 12 gr. tartar emetic is generally sufficient to effect a cure of bilharzia disease. 9. A mixture of sodium salicylate and bicarbonate of soda is useful where the drug would seem to be responsible for headache, generalised pains, rise in temperature, or skin rashes. 10. Attacks of renal colic may occur at any stage of the treatment in patients who have previously suffered therefrom; but, in the majority of cases, these attacks become less frequent as the treatment continues, and in many disappear entirely when the parasites are dead. 11. Although the male worms are more common than the females, the examination of the eggs in the centrifugalised deposit of the urine passed by the patient affords a very fair indication of the effect that the antimony is having on the eradication of the parasites from the system.

Durban, Natal

A NOTE ON THE VALUE OF

BLOOD TRANSFUSION BEFORE OPERATION

IN SEVERE SECONDARY ANÆMIAS.[1]

BY HERBERT WILLIAMSON, M.B., B.CH. CANTAB.,
F.R.C.P. LOND.,
PHYSICIAN ACCOUCHEUR, ST. BARTHOLOMEW'S HOSPITAL, LONDON

THE value of blood transfusion in cases of sudden and profuse hæmorrhage from the uterus has already been demonstrated by Dr. Russell Andrews and Mr. Gordon Luker. The case here recorded directs attention to its value in the more gradually produced anæmia of uterine fibromyomata.

M. M., aged 45, was admitted into St. Bartholomew's Hospital on May 11th, 1919. She had been married for 18 years, but had never been pregnant. Menstruation commenced at the age of 13, and was regular and normal in amount until November, 1918. From November, 1918, to April, 1919, there was amenorrhœa. Early in April vaginal hæmorrhage commenced and soon became profuse; she lost a considerable quantity of blood every day and passed large clots. Towards the end of April she commenced to suffer severe and constant pain over the left iliac fossa. The pain and bleeding continued until her admission into hospital on May 11th.

On admission she was very anæmic, restless, and breathless; the pulse was 130 of poor volume, the temperature 101° F., the tongue was dry and furred. There was incontinence of both urine and fæces and frequent vomiting. The urine contained a cloud of albumen but no renal elements.

The blood count was:—

Red cells	1,670,000 per c.mm.		Hæmoglobin	22.5 per cent.
White "	52,000 "		Colour index	0.7

The patient was so breathless that great care was necessary in moving her, and she fainted during examination. The breasts were inactive; a hard tumour was felt rising from the pelvis and reaching nearly to the costal margin, the greater part of the tumour was insensitive but one portion, situated above the right Poupart's ligament, was tender. The vagina contained blood-clot, the cervix was high up near the symphysis pubis, and behind it was a rounded cystic tumour.

From the 11th to the 17th the patient's condition gradually became worse, but I was afraid to remove the tumour. The temperature varied between 102° and 104°; the pulse between 120 and 140, vomiting was frequent and the incontinence of urine and fæces continued. On the 17th the red blood cells had fallen to 845,000 per c.mm., and the white cells had risen to 65,000 per c.mm. A differential count showed:—

Polymorphs	85 per cent	Eosinophiles	1¾ per cent
Lymphocytes	8¼ "	Basophiles	1½ "
Large mononuclears	3½ "		

On this day it was decided to transfuse the patient. The clerk of the case, Mr. Clayre, generously offered to give the blood, and both donor and recipient were found to belong to Group IV. 600 c.cm. of citrated blood was transfused into the median basilic vein. The effect was almost magical. Three days later the temperature was normal, the vomiting had ceased, she had regained control over the bladder and rectum, the red cells had risen to 3,485,000, and the white cells had fallen to 29,000 per c.mm.

I operated on June 5th. The abdominal tumour proved to be the uterus enlarged by the presence of fibro myomata showing hyaline and cystic degeneration. The tumour felt in the pelvis was a pseudomucinous cyst adenoma of the ovary. I performed subtotal hysterectomy with removal of the ovaries and tubes. Arrangements were made for again transfusing the patient during the course of the operation, but the amount of blood lost was so small that I did not consider it necessary. The patient made an uninterrupted recovery and left the hospital quite well at the end of three weeks. On the day of her discharge the red blood cells numbered 4,250,000 and the white cells 10,400.

Remarks.

I have recorded this case because it involves an important principle, and I believe the treatment adopted will enable us to save lives which would otherwise be lost. It is my intention in future to transfuse all patients in whom the anæmia is severe before operating for fibro-myomata. I believe that by this means I shall diminish the risk of the operation, lessen the liability to thrombosis, and shorten the period of convalescence. I propose also, when the patient is very anæmic, to adopt this procedure in cases of carcinoma of the cervix before performing Wertheim's operation. I have already done this in one instance with a striking improvement in the condition of the patient.

I suggest further that blood transfusion should be performed before delivery in cases of severe ante-partum hæmorrhage, and during the last few months that I had charge of the lying-in ward at St. Bartholomew's Hospital the blood of the students working in the ward was tested to ascertain their groups as possible donors.

---

[1] A paper read at a meeting of the Section of Obstetrics and Gynæcology of the Royal Society of Medicine on April 8th.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF MEDICINE.

NON-NEPHRITIC ALBUMINURIA.

A MEETING of this section of the Royal Society of Medicine was held on March 23rd, Dr. A. F. VOELCKER, the President, being in the chair.

Dr. R. L. MACKENZIE WALLIS read a paper entitled "Non-Nephritic Albuminuria." The term non-nephritic albuminuria was adopted to include all those forms of proteinuria where there was no demonstrable organic disease of the kidneys. The group included physiological albuminuria, transient albuminuria, intermittent albuminuria, the various types of functional albuminuria, orthostatic, cyclic, adolescent, &c., and a new group designated "leaky" kidneys. The chief object of the paper was to bring forward a definite group of cases which presented features akin to those found in the various forms of functional albuminuria but sufficient to warrant further discussion. In view of the results obtained in such cases, the term "leaky" kidneys had been devised, and, although not by any means a satisfactory term, it nevertheless conveyed the true significance of the condition. The question arose as to the means at our disposal for differentiating these various forms of non-nephritic albuminuria from those due to true organic disease of the kidneys. The chief protein present in the urine in nephritis was albumin, although in the blood there were both serum-albumin and serum-globulin. Further, the globulin in the serum occurred in two distinct fractions—viz., euglobulin and pseudoglobulin, the former presenting all the chief characters usually ascribed to globulin. Globulin occurred in the urine in association with albumin, but in different proportions. Thus in chronic nephritis the amount of globulin was low, but it generally increased in the later stages of the disease. The chief point was that in all types of functional albuminuria the globulin was increased in amount, and it was almost invariably of the type known as euglobulin. In "leaky" kidneys the greater part of the protein in the urine was in the form of globulin similar to euglobulin, but having associated with it an excess of lipoids, fatty acids, &c. The differentiation of these various types was based upon the following urinary tests: the production of a precipitate by the addition of dilute acetic acid in the cold, dialysis test, distilled-water test of Roberts, half saturation with ammonium sulphate, the ratio of albumin to globulin, the urinary diastase content, and microscopical examination of the sediment. The following table gave the results obtained in the various conditions:—

—	Acetic acid in the cold.	Dialysis.	Half satn. ammon. sulphate.	Ratio of albumin to globulin.	Diastase in units.
Functional albuminuria	+	+	+	2 : 1	10-22·2
Leaky kidneys ...	+	+	+	1 : 2 to 6	10-33·3
Chronic nephritis—					
Mild	0	0	0	10 : 1	10
Moderately severe	0	0	0	6 : 1	5
Severe	0	0	Slight +	5 : 1	Less than 5
Toxic nephritis ...	0	0	+ or 0	6 : 1	50-500

The globulin which is precipitated by acetic acid in the cold is euglobulin, and this test almost invariably gave positive indications in all the cases of functional albuminuria examined. This euglobulin, being insoluble in water, is also precipitated by dialysis, and gives the characteristic smoke rings when the urine is dropped into a cylinder of distilled water for the same reasons (Roberts's test). The globulin met with in the urine of the leaky kidney cases behaved in the same way, but when submitted to careful analysis was found to have lipoids and fatty acids associated with it in varying amounts. Since these associated lipoids could be extracted from euglobulin as well, the differences observed were merely differences in the degree of absorbed lipoids. This was well illustrated by the speaker's work on milky pseudo-chylous ascitic fluids. The cases about to be narrated by Dr. Tyson appeared to belong to the group of leaky kidneys, the urine of one case showing all the characters described above, and the globulin isolated containing fatty acids and lipoids. In three cases of globulinuria associated with syphilis the same changes had been observed—viz., the association of the globulin in the urine with lipoids. The maximum effect of this association was to be found in the case about to be described by Dr. Batty Shaw. Here true lecithin-globulin was isolated and the amount present was sufficient to give an opalescent appearance to the urine.

The occurrence of euglobulin or lipoid globulin in the urine was of considerable significance. Not only was it an indication of non-nephritic albuminuria, but the very simplicity of the tests for its presence in urine warranted an extended investigation of all cases of albuminuria. Further, the value of the tests as an aid to prognosis was borne out by Dr. Tyson's and Dr. Batty Shaw's cases. A case described by Bramwell and Paton in 1892 would appear to belong to the same group of "leaky" kidneys and was of particular interest in that at the autopsy no macroscopical or microscopical changes could be detected in the kidneys. As to the significance of this lipoid globulin it was at present impossible to make a definite statement. The compound had been found in all pseudo-chylous effusions which he had had the opportunity of examining. Further, in severe cases of nephritis the serum, as first observed by Bright, might become milky. The milkiness was due to the same lipoid globulin, at least in all cases of this nature which had come under the speaker's own observation. Now this same protein had been isolated from the urine in a certain group of cases which for convenience had been grouped together under the term "leaky" kidneys. This protein, or rather protein-complex, was obviously foreign to the body, and it would appear that under certain conditions it escaped through the kidneys. In doing so it apparently did no material damage to the renal epithelium, as patients continued to pass large quantities of it for years without showing any obvious signs of organic disease. The difference between this condition and functional albuminuria was one of degree, the same type of protein being present in the urine in both conditions; but there was more associated lipoid and usually much larger quantities of globulin were passed in leaky kidney cases. The hope was expressed that the subject of globulinuria would receive attention, and that the tests would be applied to every urine where albumin had been detected, especially where no obvious cause for its presence had been determined. The above tests proved far more reliable than merely testing the urine for albumin, or than assessing the doubtful significance of certain types of casts in determining the nature of the case.

Dr. H. BATTY SHAW reported on a case of

An Unusual Form of Turbid Urine due to the Presence of Lecithin-Globulin.

The patient, a young man of 37, had suffered from what appeared to be albuminuria for 18 months, and for the first half of this period was diffusely dropsical. Casts of a fatty character were found in his urine, so that the case appeared to be one of chronic parenchymatous nephritis. The patient had suffered from syphilis eight or nine years previously; but the nephritis was probably not due to this infection because the Wassermann test was always negative. The urine presented two special features which were of interest to the clinician. It was uniformly turbid on several occasions, and the turbidity was not due to micro-organisms; further, the usual tests for albumin produced a most bulky precipitate which appeared to be supported in a gelatinous matrix. These two unusual features were elucidated by Dr. Mackenzie Wallis, who showed that the protein present was globulin and not albumin, and that the turbidity of the urine was due to the inability of the urine to maintain in solution the large amount of the complex which was present—namely, lecithin globulin.

This case differed from the cases described by Dr. Mackenzie Wallis in that the globulin was present not in a case of functional disorder, but in a case which appeared, clinically at least, to be one of chronic parenchymatous nephritis. It was of further interest because it was the first case described in which turbidity of urine was due to the presence of lecithin globulin, a complex which, as Dr. Mackenzie Wallis had shown elsewhere, is responsible for the turbidity and milky-like appearance met with in chyliform or pseudo-chylous ascitic or pleural effusions.

Report on Three Cases.

Dr. W. J. **TYSON** reported three cases. Case 1 was that of a man, aged 70, whose urine had been tested first in 1905 and frequently up to the time of his death in 1914. Albumin had always been present, but the quantity had varied from a slight amount to absolute solidity. It increased with any feverish cold. A very careful examination had been made in Switzerland in 1907, when the report stated that the urine was acid, of specific gravity 1007, without sugar or casts, but containing much albumin. He never had signs or symptoms of Bright's disease, no œdema or dropsy, no increase of pulse tension, no eye troubles. Case 2 was that of a man aged 76, who for 17 years had had albuminuria varying from enough to cause solidity on boiling to 1/10 by Esbach's method. His pulse tension was not high. He was liable to giddy attacks and transient aphasia. Case 3 was that of a woman aged 70. When first seen in 1911 she was insensible and pulseless, and the urine solidified on boiling. Within two days the patient became sensible, the albumin disappeared, and she became otherwise normal. There was no further evidence of Bright's disease. He had seen no other cases similar to the above. The enormous amount of albumin present at times, with practically an absence of it at other times, and with none of the ordinary symptoms or signs of Bright's disease, seemed to warrant the placing of these cases in a class by themselves. These people lived for a long time and carried on their life and duties as usual. He thought that the passage of albumin with or without hyaline and finely granular casts was a comparatively common condition, especially in those over 50 years of age, and was of little or no practical importance. That people reaching middle life had often been rendered miserable by the finding of albumin there was no doubt.

Sir **NESTOR TIRARD** said that Dr. Mackenzie Wallis's work constituted a distinct advance. He asked what was the cause of death in Dr. Tyson's first case, and on learning that it was from double pneumonia, inquired whether the patient had previously undergone salvarsan treatment. In certain cases recorded by Byrom Bramwell, in which salvarsan had been employed in the treatment of anæmia, death from pneumonia had taken place. Hyaline casts he regarded as of very little importance. Centrifugalised fresh urine might show hyaline casts, but they might disappear if the urine stood for some hours; he believed that they became dissolved. He expressed himself as still unrepentant, as an examiner for life assurance, of advising extra premiums in cases with albuminuria, in the present state of our knowledge.

Dr. O. **LEYTON** recorded a case of a man, aged 35, whose urine when he first examined him became solid on boiling. Eighteen months later the urine still became solid and serum albumin was in excess. The blood pressure was not raised and there were no ocular changes. *B. coli communis* was present in the urine. Some years before he had suffered from gonorrhœa, the urine had not cleared after this and he had been in the habit of taking hexamine freely. Ten years later his prostate was removed, but the kidneys were still efficient, and the operation was performed without difficulty. He was now 90 years old. There had been recognised albuminuria for 14 years and he was still healthy. In cases of postural albuminuria calcium lactate had appeared to diminish the albumin.

Dr. J. H. **THURSFIELD** said that the patients with "albuminuria" who were particularly interesting were those who were rejected for life assurance, or whose premiums were heavily loaded. There were such patients without nephritis and without any tendency to it. The majority of these were passing lecithin globulin. There were no casts and no other symptoms of nephritis, with the exception that a few had œdema of the feet. The œdema he regarded not as true renal œdema, but as being in the same category as similar œdema met with in orthostatic albuminuria. In orthostatic albuminuria in children the abnormal protein passed was almost entirely or wholly serum globulin, and these children occasionally had œdema of the feet. It was the duty of insurance medical officers, when confronted with albuminuria without signs of Bright's disease, to see whether it was globulin which was present, for in that case the candidates could be insured as first-class lives with absolute safety.

Dr. R. **HINGSTON FOX** said that the insurance officers did not hold so restricted or ignorant views as seemed to be implied. The question of albuminuria without nephritis had been muddled by a multiplicity of terms. He was familiar with cases of harmless albuminuria. Typically they were cases of rapidly growing young men, pale, suffering often from headaches, easily flushing, and with readily elicited "tache." In such cases calcium lactate almost always removed the albumin temporarily if given in doses of a drachm on two successive evenings. Insurance officers passed these cases with little modification. Whether the condition was altogether free from ill effects was still a matter of opinion, and from the point of view of insurance it was therefore justifiable to decline to treat the individuals as first-class lives.

Dr. W. P. S. **BRANSON** said that insurance medical officers did not treat candidates with "albuminuria" in so unreasonable a way as some seemed to suppose. The difficult case was that of the man of from 35–45 who came for the first time with albuminuria.

Dr. **MACKENZIE WALLIS**, in his reply, said that he knew of three cases of syphilis in which globulinuria persisted after salvarsan treatment. Cystoscopic examination in cases of orthostatic albuminuria had shown that no urine emerged from the left ureter when the patient was standing, which suggested that the albuminuria was due to pressure on the left renal vein.

SECTION OF OBSTETRICS AND GYNÆCOLOGY.

EXHIBITION OF CASES AND SPECIMENS.

A MEETING of this section of the Royal Society of Medicine was held on April 8th, Mr. J. D. **MALCOLM**, the President, being in the chair.

Douche-nozzle Removed from the Female Bladder.

Mr. T. G. **STEVENS** showed a specimen of a gum-elastic douche nozzle, the third which he had had occasion to remove from the female bladder. It had been in the bladder nearly three months and a severe cystitis had developed. The bladder was incised per vaginam and the nozzle found to be so encrusted with phosphate crystals as to require cutting in half before removal. The bladder was sewn up at once with catgut, the vagina having been separated ¾ in. all round the opening and sutured separately. A self-retaining catheter was inserted and removed on the tenth day, when the urine was almost free from pus and the incision was apparently healed. A few days later there was a transient doubtful leakage, but the patient was discharged three weeks after the operation, able to hold urine all night without inconvenience. The severe cystitis did not prevent the healing of the incision in the bladder.

Dr. **AMAND ROUTH** said that the vaginal route was undoubtedly the best for removing such a foreign body, but his practice was to leave the bladder open.—Dr. **HERBERT SPENCER** suggested that the specimen might have been cut in half and removed through the urethra by means of a Kelly's tube.—Dr. A. **LAPTHORN SMITH** agreed with Mr. Stevens's method, except that he preferred to make the incision in the vagina ½ in. to the right of the middle line, and that in the bladder ½ in. to the left, to avoid leakage.—Mr. STEVENS in reply said that the difficulties encountered in the previous cases in trying to remove the nozzle per urethram had prevented him from repeating the attempt. As to sewing up the bladder, he had left his first case open and it had not healed readily, so he sewed up the two subsequent cases with complete success.

Cystic Embryoma of Ovary.

Mr. J. D. BARRIS showed a specimen of Cystic Embryoma removed from a nullipara, married one year previously. There was a history of two months' abdominal pain; menstruation normal. A pseudo-mucinous ovarian cyst was removed from the right side. The specimen shown consisted of the left ovary, opened to show an upper cystic and a lower solid unaffected portion, and was unusual in that it showed a *pedunculated* dermoid situated within a cyst cavity lined by old blood clot.

Combined Placenta Prævia and Accidental Hæmorrhage.

Dr. EARDLEY HOLLAND gave a short account of a case of Combined Placenta Prævia and Accidental Hæmorrhage. The patient was a primigravida of 28. When first examined, after she had bled moderately for about four hours, the placenta was felt overlapping a cervix dilated to the size of two fingers. She appeared more anæmic than was warranted by the amount of blood lost externally. The uterus was hard and irritable, and the urine contained a dense cloud of albumin. A leg was brought down and continuous weight-traction made upon it. She soon delivered herself of a dead fœtus. The placenta, which followed almost immediately, was accompanied by a large dark clot of about 14 oz. of blood. Examination of the placenta revealed a typical, sharply localised depressed area in the middle of the maternal surface and occupying about one-third of its area. Blood clot was still occupying parts of this depressed area, and closer inspection revealed some adherent laminæ of greater age. The opening in the bag of membranes was at the margin of the placenta. Dr. Holland said that this was a true case of placenta prævia combined with toxæmic retroplacental hæmorrhage. There was no inherent reason why such a combination should not occur. As the frequency of placenta prævia was given as 1 in 1000 and that of accidental hæmorrhage as about 1 in 500, by the laws of chance the combination should occur about once in every half-million cases of placenta prævia.

Infected Fibromyoma of the Uterus.

Dr. HOLLAND then showed a specimen of an infected fibromyoma of the puerperal uterus removed by hysterectomy. The patient was admitted into the London Hospital with all the signs of an acute generalised peritoneal infection; a tender, hard tumour was felt rising above the pelvis, the size and shape of a uterine pregnancy of 24 weeks' duration. She had been delivered of a dead premature fœtus three weeks previously; the placenta had been removed manually three days after labour. Immediately after admission the uterus was removed by subtotal hysterectomy; the peritoneal cavity was drained through the vagina and through the abdominal wound. The patient died in 36 hours. The whole of the anterior wall of the uterus was occupied by a single, spherical, necrobiotic fibroid, 15 cm. in diameter. The particular interest in the specimen lay in the fact that there were two perforations of the capsule of the fibroid on its anterior peritoneal wall, and one perforation through the posterior wall of the capsule into the infected uterine cavity. Between these perforations was a continuous purulent track, lying between the fibroid and its capsule, and forming a path of infection from the uterine to the general peritoneal cavity. The perforations were, no doubt, due to acute necrosis from a virulent infection acting on a capsule rendered tense by the rapid swelling of the fibromyoma it contained.

Extensive Fatty Change in Fibromyomata.

Dr. HERBERT WILLIAMSON and Dr. R. St. L. BROCKMAN submitted a short communication on two specimens, one showing a Fibro-myo-lipoma of the Uterus, and the other Extensive Fatty Degeneration of Uterine Fibromyomata. The first specimen was from the museum of St. Bartholomew's Hospital, and showed an ovoid, encapsuled tumour composed of fat, situated in the interior of the uterine fibromyoma. Microscopical sections of the tumour showed that it was a true lipoma, and that the fat was contained within typical fat cells. The authors described six similar tumours of which descriptions had been published, and referred also to another specimen in the museum of the Royal College of Surgeons of England. They discussed the origin of such tumours, and preferred the term fibro-myo-lipoma to the terms lipomatosis and fatty metamorphosis, inasmuch as it involves no theory of origin. They saw no difficulty in accepting the view that these tumours arose from the metamorphosis of fibrous tissue or muscle cells of a fibromyoma, since such a metamorphosis had been proved in the case of sarcoma cells, but as no transition forms had yet been demonstrated the matter could not be regarded as proved. They drew attention to the fact that, with one exception, all the tumours were removed from patients over 50 years of age, having given rise to bleeding after the menopause. The second specimen was shown as a contrast; it consisted of a transverse section through a mass of uterine fibromyomata. In the recent state these appeared to consist of yellow fat, and oil globules could be scraped from the surface. The sections showed that the presence of fat was due to extensive fatty degeneration, and that the fat was not contained within typical signet-ring cells, as in the specimen first exhibited.

Dr. CUTHBERT LOCKYER said that the question for decision was whether the condition in these cases was a degenerative change or a neoplasm. The familiar fatty degenerations of fibroid, whether red, white, or yellow, were of a granular lipoid nature, in no way resembling the sunset-coloured signet-ring shaped cells described by Dr. Williamson and Dr. Brockman, and also found in the speaker's own case. He had eliminated the possibility of a neoplasm in his case, and therefore objected to the nomenclature advocated by the authors. He considered that the change affected the muscle rather than the fibrous tissue fibres, as he had traced globules running in the direction of the muscle fibres and could distinguish nuclei in them.—Mr. STEVENS thought that the incomplete encapsulation and the strands of fibromuscular tissue running into the fatty mass were points against a neoplastic origin. A lipoma consisted of fibrous tissue and fat only, while myo-lipomata were unknown.

A Case of a Pregnant Woman with High Ammonia Coefficient.

Lady BARRETT described a case of a pregnant woman with a high ammonia coefficient and persistent vomiting, who recovered and gave birth to a normal living child at term. The patient, a munition worker aged 22, was admitted to the Royal Free Hospital with persistent frequent vomiting when about six weeks pregnant. The vomiting was accompanied by constipation and treated by dieting, with occasional success, till a month after admission it became more severe and diacetic acid appeared in the urine, which was scanty (7 oz. in 24 hours), and contained also a faint trace of albumin. The vomiting improved for two days, during which the patient had Benger's food by the mouth, but it started again and she was put on glucose saline per rectum, with the subsequent addition of albumin water and tea by the mouth. The ammonia coefficient rose to 38 and subsequently to 78, and the quantity of urine passed in 24 hours varied from 5 to 24 oz. daily. The vomiting ceased gradually, and the diet was increased in protein content in the hope that the ammonia coefficient, which still remained at 50, would decrease on a more generous intake of nitrogen. This hope was realised, and about eight weeks after admission to hospital the vomiting had practically ceased, the ammonia coefficient had fallen, and the urine excretion risen. After a slight relapse the patient's condition improved steadily, and she was discharged 12 weeks after admission. She was readmitted when 6½ months pregnant, with loss of appetite, drowsiness, and persistent vomiting. The ammonia coefficient was then only 5 to 7 and she was discharged 10 days later. She was delivered at term, after a normal labour, of a girl weighing 5 lb. 9 oz., jaundiced at birth; mother and child both did well. For nine months, during which the patient was kept under observation, the ammonia coefficient remained between 5 and 8. She then became pregnant again, about 5 months ago, and is now under observation. The ammonia coefficient remains low and the patient well. Lady Barrett suggested that the successful termination of the case, the progress of which had been watched from day to day with a view to inducing labour if necessary, indicated that the general condition, pulse, and quantity of urine passed, and the presence or disappearance of diacetic acid in the urine, were of more importance in deciding on the need for induction than a high ammonia coefficient.

The PRESIDENT congratulated Lady Barrett on her successful conduct of the case.—Dr. MACKENZIE WALLIS said that the case was very surprising. He had never come across an ammonia coefficient higher than 38. He asked whether the nitrogen in the blood, and the diastase in the urine, had been estimated. The latter sometimes remained high for a long period. He was struck by the small quantity of diacetic acid present.—Dr. T. W. EDEN described a case differing from Lady Barrett's, but also illustrating the vagaries of the ammonia coefficient. Possibly the explanation of the excellent result notwithstanding the high figure found by Lady Barrett was that it was due to the starvation following on the vomiting rather than to toxæmia.—Lady BARRETT, in reply, said that separate estimates of amino acids had not been made in the first illness. Since then the amino acids had been present in small proportions relative to the ammonia. Diacetic acid was only rarely present. Diastase had not been estimated.

The Value of Blood Transfusion before Operation in Severe Secondary Anæmia.

Dr. HERBERT WILLIAMSON contributed a Note on the Value of Blood Transfusion before Operation in Severe Secondary Anæmia, reported in full on p. 867 of our present issue.

In reply to a question by Dr. ROUTH, Dr. WILLIAMSON said he never used saline injections since the blood pressure was not increased thereby, but the saline filtered through into the tissues, causing œdema. He had had good results with 6 per cent. gum arabic in saline—though not so good as with blood—and this solution had the advantage that it could be stored and used when blood was not available.

Rupture of the Vagina during Labour.

Dr. A. C. PALMER described two cases of Rupture of Vagina during Labour, admitted to the Obstetric Department of the London Hospital. An 8-para, aged 35, was brought by her doctor, who stated that the case was one of prolonged second stage with the head delayed in the pelvis. He had extracted a child, still-born, weighing between 13 and 14 lb., after a hard pull with forceps. The perineum was torn. The placenta did not follow and since the patient continued bleeding he decided to remove it manually. Following the umbilical cord, his hand passed into the abdominal cavity, where he found and removed the placenta. The case was then brought up to hospital; P. 120, T. 98° F., abdomen very tender. The uterus was found almost completely separated from the vagina, except for a narrow bridge in the region of the left uterine artery, and a small portion of the anterior wall of the cervix close to the bladder. There was much free blood in the peritoneal cavity. The uterus was removed as rapidly as possible, and the patient made a good recovery. Dr. Palmer believed that the difficulty was due to relative pelvic contraction owing to the very large size of the child. The second case, also a multipara, was brought to hospital in a state of collapse (P. 120, T. 96·5°) by a midwife, having been in labour for 24 hours. There had been good pains for 15 hours, and since then the pains were described as tempestuous and different in character from the preceding ones. No manipulation and only one vaginal examination had been made. On the right of the fœtus was a hard tumour about the size of a fœtal head, and thought by the resident accoucheur to be possibly a fibroid. A moderate pull with forceps being unsuccessful, the child was delivered after perforation and crushing of the head by Mr. V. J. F. Lack, the resident accoucheur, who then noticed that the tumour was the contracted uterus and that the child had been lying in the abdominal cavity, whence the placenta was removed manually. At an exploratory laparotomy Dr. Palmer found a large T-shaped tear in the posterior vaginal wall, beginning at the cervico-vaginal junction and extending almost down to the vulva, and much free blood in the peritoneal cavity. The uterus was rapidly removed. The patient is now convalescent. Four easy labours had occurred in spite of well-marked general contraction of the pelvis; the fifth had required forceps; the sixth was the case described. In each case the object of the hysterectomy was the control of hæmorrhage and the removal of damaged and devitalised tissue as a prophylactic against puerperal sepsis.

Sacculation of a Gravid Bicornuate Uterus.

Mr. T. G. STEVENS described a case of Sacculation of a Gravid Bicornuate Uterus. The patient was admitted to St. Mary's Hospital in great pain, having been in labour two days. The uterus, nearly full term in size, was not contracting very powerfully and the fœtal head was at its upper part. Per vaginam the os was out of reach and a fluctuating swelling filled the upper half of the pelvis behind. Pulse 104, temperature 97° F. Three months previously an immovable swelling, then smaller, had been felt by Mr. Stevens behind the cervix; it was then diagnosed as an ovarian cyst and left, with the idea that during labour the cyst could be removed by operation and delivery then completed per vias naturales. As the cervix could not be reached it was, however decided to perform Cæsarean section and then to deal with the tumour. The fœtus having been extracted from an apparently normal uterus, this was drawn through the abdominal incision and the pelvic swelling was found to be a sacculation of the uterus itself, formed by the slightly distended posterior wall. The actual fundus was held down in the pelvis by an adhesion 1¼ in. broad by ⅛ in. thick. Further, a solid projecting mass, proving to be the enlarged, thickened, but not expanded, half of a bicornuate uterus, was found attached to the left side of the expanded anterior part of the uterus. The cervix was located as a flattened structure, hardly at all dilated, in front of and below the impregnated half of the uterus, and making an acute angle therewith. Both mother and child did well. Mr. Stevens said that sacculation of the gravid uterus was a rare condition, usually attributed to retroflexion in early pregnancy, but in this case due to the adhesion of which the cause remained obscure.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of the Pathological Section of this society was held on March 18th, Dr. J. F. Gemmell, the President, in the chair.—Professor Ernest Glynn contributed a critical review of so-called "ovarian hypernephromas." He was of the opinion that such tumours were exceedingly rare if they ever did occur, and gave three reasons for his view: 1. There was only one recorded case of a cortical rest in the ovary (1913) and even this was doubtful and unconfirmed by other observers. Such rests were undoubtedly found frequently in the broad ligament. 2. Ovarian hypernephromas were never associated with hirsuties and changes in the sex characters so common in primary neoplasms of the adrenal cortex in women before the menopause. 3. There was little, if any, difference, clinically and histologically, between ovarian tumours described as "hypernephroma" and as "malignant lutein" formations respectively, yet both these tumours were apparently quite unlike true neoplasms of the adrenal cortex itself.—Dr. G. F. R. Smith read a paper on the urine after anæsthesia based on a quantitative investigation of acidosis following various types of anæsthesia. He noted the development of acidosis after ethyl chloride and ether as well as chloroform and discussed predisposing causes. He was of the opinion that warmed ether given by the open method to a patient not unduly starved before operation was the safest anæsthetic available.

Reviews and Notices of Books.

Entomology for Medical Officers.

Second edition, revised. By A. ALCOCK, C.I.E., M.B., LL.D., F.R.S., Professor of Medical Zoology in the University of London, Lecturer on Entomology (Medical) at the London School of Tropical Medicine, &c. London: Gurney and Jackson. 1920. Pp. 380. 18*s.*

ENTOMOLOGY is a subject of surpassing interest, and no branch of it is more so than that dealing with the part insects play in the spread of disease. We advise those wishing information on the subject to get a copy of Colonel Alcock's book, a second edition of which has just been published. Dedicated to Sir Patrick Manson, the founder of modern tropical medicine, the book is replete with information and pleasant to read. Take, for example, the opening paragraph, on p. 31, to the chapter on Insecta; here the author says: "It is sufficient to say that insects outnumber all other species of animals put together, that it is impossible to overestimate their natural influence and momentum, and that so far as their relation to civilised man is concerned insects have in various ways retarded his most resolute efforts to replenish the earth, and have at times and in places disputed his very dominion." So true is this that it behoves all medical practitioners, and especially those whose lot is cast in the hot parts of the earth, to have much more than a smattering of knowledge of the subject. Both medical man and layman, not specially trained as entomologists, will find all that they require in these pages.

A Primer of Tropical Hygiene.

Sixth edition. By Colonel R. J. BLACKHAM, C.B., C.M.G., Assistant Director of Medical Services. Bombay: G. Claridge and Co. 1919. Pp. 154. Rs.1.

WITH the extension of foreign and colonial trade and the opening up of the African continent the number of people who would benefit by a knowledge of tropical hygiene will be considerably increased, and we therefore welcome a new edition of Colonel Blackham's excellent primer. The fact that it has gone through five editions in as many years testifies to its popularity, and its usefulness is also emphasised by its adoption as the official handbook for the classes at the College of Ambulance for teaching Europeans the rules of health in tropical and subtropical countries. The chapters, of which there are 12, deal with ventilation, water-supply, and various aspects of personal and public hygiene.

Manual of Obstetrics.

Second edition, revised. By EDWARD P. DAVIS, A.M., M.D., F.A.C.S, Professor of Obstetrics in the Jefferson Medical College, Philadelphia. London and Philadelphia: W. B. Saunders Company. 1919. Pp. 478. 15*s.*

THE appearance of this second edition has been delayed by the war. The section dealing with the differential diagnosis of early pregnancy has been revised. Great stress is laid on Hegar's sign, but as the student is not definitely told what the author means by this sign he is not likely easily to recognise it. In the description of chorion epithelioma we are told that a layer of fœtal cells called the syncytium covers the villi, but no mention is made of Langhans' layer. There is no account of the exact pathology of hydatidiform mole; the student is told that the diagnosis is made by the rapid increase in the size of the uterus and the passage of masses of small cysts, but nothing is said of the many cases in which neither of these signs is present. The author favours ether as an anæsthetic for labour cases and is evidently not in favour of twilight sleep. A good account is given of the modern method of performing Porro's operation in cases where the uterus is infected, and it is not safe to drop the stump back into the peritoneal cavity after hysterectomy. The book is an interesting one, but it is intended for the students attending the author's lectures at the Jefferson Medical College, and the teaching differs in many particulars from that prevalent in this country.

Physiology of the Central Nervous System and Special Senses.

For the Use of Students. Third edition. By N. J. VAZIFDAR, L.M. & S., Assistant Chemical Analyser to Government of Bombay. Bombay: S. Govind and Co. 1920. With 18 illustrations. Pp. 210. Rs. 3.12.

THIS opuscule has obviously undergone considerable emendation since we reviewed it in THE LANCET, Dec. 7th, 1912, but it is still capable of improvement. In dealing with the size of nerve cells, nowhere is any definite size stated; neuro-fibrils of nerve protoplasm are not, as stated, easily demonstrated by Cajal's method. Proof-reading is defective, as shown by such mistakes as the following: Dieters, Billarger, headace, Gower's Tracts, apperture, intensitive, Danders, pulviner. There are many others. It would be difficult to recognise a Pacinian corpuscle from the description given on p. 144, or to demonstrate the blind spot from the directions on p. 187, where the asterisk and † are reversed in position. We are told that "the elasticity of the lens is best seen when it is removed from the eye of a young person; it immediately assumes a spherical form." The rods and cones do not rest on the external limiting membrane, nor is "the path of taste sensations" from gustatory cells through the "lingual nerve and then through the chorda tympani." It requires a thorough knowledge of a subject to be able to make an accurate compilation, which this can hardly be said to be; still, in its broad outlines it may prove useful for those students for whom it is written.

Medical Guide for India and Book of Prescriptions.

By Lieutenant-Colonel E. J. O'MEARA, O.B.E., F.R.C.S. Eng., D.P.H. London and Calcutta: Butterworth and Co. 1920. Pp. 722. Rs.12.

THE guide is designed as a ready reference of domestic medicine, especially for students and practitioners in India. It is a careful compilation, and should prove very useful if its employment is limited to the scope laid down in the preface. Obviously, in short paragraphs of potted medicine the teaching must be dogmatic, but the author has been careful in the avoidance of dangerous doctrines. A most interesting section deals with the indigenous drugs of India. Colonel O'Meara is convinced that the native physicians possess prescriptions which are "of great use," but any attempt to extract information is met with "courteous but absolutely evasive answers." The knowledge which is withheld should prove a stimulus to research in a not unpromising field, and the author is expecting important achievements from a committee on indigenous drugs which has been appointed in Bombay.

Electrical Treatment.

Third edition. By WILFRED HARRIS, M.D., F.R.C.P. London: Cassell and Co., Ltd. 1919. Pp. 354. 9*s.* net.

THE general plan of this edition of Dr. Harris's "Electrical Treatment" remains unchanged. As in the second edition, the major portion of the book deals with the faradic and galvanic currents—their production and the maladies which can be treated by them, particularly those of the nervous system. Considerable space is devoted to descriptions of the pathology and symptoms of some of the diseases of the nervous system. A clear account is given of the medical coil and galvanic cells and batteries. Two chapters are devoted to the sinusoidal current and its medical uses. One of these chapters contains an interesting account of dynamos and motors. The author frequently uses the term "cataphoresis" in place of ionisation. The older term should be discarded as it really means a transport of fluid from the anode towards the kathode and not the migration of ions. Although static electricity and high-frequency currents are very briefly considered and less than a page is devoted to diathermy, this book will form a useful addition to the library of the practitioner of electro-therapeutics, and will be a valuable guide in the treatment of diseases of the nervous system by simple electrical methods. It is well prepared and there is a good index.

THE LANCET.

LONDON: SATURDAY, APRIL 17, 1920.

The Future of the Hospitals.

THE voluntary hospitals, like many persons and other institutions, are feeling the pinch of the war, but their needs, as put before the public imagination, represent them as in a desperate plight, We trust our readers to take every opportunity which opens itself before them to paint a more accurate picture of the circumstances than is thus conveyed, while it is fair to ask certain critics of the voluntary system to be more certain of their ground and more specific in their statements. Before the assertion is made that the voluntary hospital system is doomed, we want to know whether it has broken down at all or whether the acknowledged pecuniary stress under which the work is being carried on is, at any rate to a large extent, an expression of the general condition of our social world—whether, in other words, we are dealing with circumstances which, however grave, should be temporary and not imply permanent failure. Our contemporary *The Hospital* protested recently against persistently pessimistic estimates of the future of voluntary hospitals, pointing out that if the voluntary system, as it existed before the war, is inadequate in the present situation, as proved by what the war has left behind it, the lesson is not that the voluntary system has broken down, but rather that it requires an added support commensurate to added needs. This was much the view put forward in these columns when we were dealing with the voluntary hospitals of the metropolis, premising that if in the metropolis the voluntary principle was not condemned it might be assumed to have reasonable chances of living elsewhere. The figures supplied in the last statement issued by King Edward's Hospital Fund for London on the present position of the London voluntary hospitals showed that for the time being an increase of little more than 10 per cent. in the annual subscriptions would meet the net deficiency; and when it is remembered that we are talking of a total annual expenditure of well over two millions it will be seen that, so far as London is in question, the voluntary system is no failure.

London, however, in matters of social administration, can never be taken as typical of the rest of the country, while those who by training, temperament, and experience are most closely wedded to the voluntary principle, admit that the time has come when a certain amount of State or municipal aid will be required, if the hospitals are to play their proper part in a world that is developing with good intentions, though often upon profoundly uncomfortable lines. Now, it seems to us to be quite impossible for anybody at the present moment to speak with exactitude as to how this aid should be supplied and in what selected directions it should be employed. The necessary knowledge is simply not before us, and those who draw deductions as to the permanent failure of the voluntary system from particular complaints emanating from certain institutions are unwisely hasty. At this juncture we want, and we are shortly going to obtain, wide and accurate information as to the real incomes, expenditures, and services of all the larger voluntary institutions; then and then only can we gauge, with truth and justice, both what is the measure of success or failure, and what are the directions in which the State or the municipality can, and should, come to the rescue. The Red Cross has already distributed large sums of money, and proposes to raise further money under a scheme of equivalently large prevision, whereby funds to hospitals will be supplied according to the merits of the institutions, the national needs which they meet, and their standards of economy and efficiency. The information thus needed at the centre is being carefully collected—and the time, patience, and energy comprised in the word "carefully" will surprise all; and when the time comes for action, the grants, donations, and pecuniary support will be offered by the Red Cross with a single eye to raising the general standard of hospital treatment and management. Supported in this way by help in the right places and at the right times, voluntary subscriptions, we are sure, will go far towards meeting the immediate case. But the Red Cross scheme will also contain suggestions whereby the hospital population may itself be diminished, by the foundation of convalescent homes among other things, and by the proper development of after-care associations, while central buying schemes are proposed whereby sporadic extravagances may be eliminated in the cost of food and nursing material. The lesson of all this seems to us to be that in such circumstances it is short-sighted to ask the public at the present juncture for more money to add more beds to particular institutions; these may not be found necessary in the particular place where it is proposed to supply them, when the need for beds is estimated under some general plan over an orderly selection of areas.

To quote a phrase once familiar in educational circles and already applied by ourselves to the present position of hospitals, the duty of the State should be, at any rate for the present, that of supplementing the voluntary hospitals, not of supplanting them; but it is necessary that those who use this argument should be able to say in what particular directions the State or county or municipal subsidy should be sought. The attempt has been to institute some parallel between what happened and is happening in education and what will happen in hospital provision. It will be remembered that the main reason for the existence of voluntary schools, when State elementary education was provided, was that the voluntary schools preserved the religious element. They were allowed to continue their work, the State taking over the responsibility of part of the maintenance, that for the buildings remaining with the foundation managers. At the present moment there are numerous voluntary schools, whose measure of independence is respected and whose work is highly valuable. Has not this position a lesson for us in respect of the voluntary hospitals, especially if we consider the case of continuation rather than elementary schools? For hospitals should not be classed as elementary institutions; they are more comparable to continuation and special schools, for only those patients should find their way to hospitals whose needs have not been already met in the ordinary routine of panel practice. If we regard the hospital population of the country as composed to some extent of defectives from physical standard, it would certainly seem logical that the State should assist along all the special lines needed to prevent and to recuperate.

Food Pigments and Accessory Food Factors.

AN interesting suggestion in regard to the nature of the fat-soluble accessory food factor is made in an article published in our present issue. The authors, Dr. O. ROSENHEIM and Dr. J. C. DRUMMOND there record the results of a number of experiments carried out with the view of ascertaining whether the accessory substance is related to, or is identical with, a member of the class of pigments which are found in association with fats. These pigments are termed lipochromes and typical examples occur in the yellow pigment of egg-yelk, butter-fat, and in vegetables, all of which are known to possess either growth-promoting or antiscorbutic or antineuritic properties, or all three. These researches gave promise of isolating the active accessory constituent, but the authors come to the somewhat disappointing, if interesting, conclusion, that, whilst the identity of the fat-soluble accessory food factor with a known lipochrome pigment appears to be improbable, there are reasons for assuming that it is in some manner associated with this group of substances. It is a remarkable fact, at all events, that the colour of body-fat, milk-fat, or egg-fat is derived from the lipochrome pigments ingested in the diet.

The normal yellow colour of butter is known to be due to carrotene,[1] a hydrocarbon with high oxygen absorption capacity, and, besides, there is present xanthophyll, similarly constituted, but with two atoms of oxygen attached. It is significant that these pigments have their origin in the grass and roots consumed by the cow, and an interesting fact is that, should the source of these pigments be cut off, as for example, by maintaining the animal on a diet of bleached hay and white corn, the butter-fat becomes progressively paler until it is practically white. Should further investigation confirm an intimate relationship between the lipochromes and the fat-soluble accessory factor, and possibly the water-soluble factors too, new questions will arise as to the bleaching of food products. Fresh evidence would then possibly be acquired of the dietetic deficiency of the white loaf, and the dyeing of milk with annatto would mean a false sense of security as regards the presence of a growth-promoting factor. The evidence so far that lipochromes are necessarily associated with important nutritive factors, though not convincing, may give a much-desired clue as to their nature and composition. It is very suggestive, at all events, as evidenced by a table presented by the authors, that the distribution of lipochromes and fat-soluble A in a number of fats runs parallel. In those cases where a negative is recorded for lipochromes, as with white fish, lard, and vegetable oils, so also is a negative recorded for fat-soluble A. That alone is remarkable, and we welcome the authors' announcement that they are pursuing the matter further. The question of pigments playing a rôle in nutrition is all the more interesting when we remember how important is the function of chlorophyll in plant life and of hæmoglobin in animal life.

In an interesting paper on a related subject, also published in our present issue, Dr. E. MELLANBY deals with the question of accessory food factors in the feeding of infants. The subject was discussed at a meeting of the Royal Society of Medicine held on Feb. 17th, and the proceedings were reported in THE LANCET of March 13th (p. 604). The article is illustrated with an interesting series of photographs of puppies fed on a rickets-producing diet, and a group of radiograms of the wrist-joint is reproduced showing when rickets did or did not occur. Coming to practical considerations, Dr. MELLANBY referred to the remarkable immunity from rickets enjoyed by Jews as against Gentiles amongst school children. It is a significant fact that the dietary of the former includes much fatty food, oil, eggs, and milk, while such food materials do not form a substantial part of the dietary of the latter. These results appear to be in complete agreement with a valuable series of biological experiments conducted in the laboratory which we have consistently recorded. The useful observations were made by Mr. WILLIAM HALL, in Leeds, as far back as 1902, when the presence of the antirachitic accessory factor in food was undreamt of. The inference (backed by a consideration of the remarkably good health of the children in the Hebrides brought up on breast-milk and a surplus of fatty foods, including fish liver) is that inferior physique in infant life depends not so much on environment as upon diet deficiency. Practical returns of this kind show us that the energetic work of our biologists is proceeding on illuminating lines.

---

[1] Chemical Society Nomenclature.

The Medical Problems of Life Assurance.

We publish in our present issue an interesting and suggestive paper by Dr. T. D. Lister under the above heading, being an abstract of the presidential address delivered before the Assurance Medical Society on March 12th. The problems of assurance medicine are varied and somewhat complex, since they involve, for the most part, questions of prognosis, which are almost proverbially dangerous and difficult in regard to individual cases. At the same time, as Dr. Lister points out, there is some safeguard to the assurance medical officer at the head office in the fact that he has rather to place "lives" in classes than to insure individuals. Medico-actuarial calculations afford statistics of real value in prognosis, and they have perhaps not received the general attention they deserve. Collective investigation of assured lives and later, if it be possible, of declined lives would probably afford most valuable data to medicine in general as well as to assurance medical officers. Dr. Lister's rather happy illustration of "vital trajectories" is an idea which might be developed with very good results.

It is of interest to note that one of the problems to which Dr. Lister referred has been considered recently by the Section of Medicine of the Royal Society of Medicine—viz., that of Non-nephritic Albuminuria; and we publish on p. 868 an abstract of the paper on this subject by Dr. Mackenzie Wallis and of the discussion which followed. We can commend the perusal of this paper and discussion to our readers, especially those who are concerned in the examination of candidates for life assurance. It would appear that in non-nephritic cases the chief protein in the urine is euglobulin often in combination with lipoids. It is of special interest to note that the tests for the recognition of this substance and its differentiation from albumin are simple, easy of employment, and do not require much time for their application. From the discussion, at which some assurance medical officers were present, it is evident that there is no uniformity of opinion or practice in dealing with cases of albuminuria in candidates for life assurance. We believe the usual custom is to postpone the candidate for further investigation of the urine and to accept the proposal, with or without some slight loading, if the condition is of the nature of functional or cyclical albuminuria. Further research on the lines set out by Dr. Wallis appears likely to simplify the problem for the examiner by affording an easy method of distinguishing the "albuminurias" of organic origin from those of functional nature.

A further aspect of life assurance medicine was raised in a recent paper by Dr. R. T. Williamson, dealing with the discovery of glucose in the urine of candidates for assurance. He gave some valuable suggestions for dealing with this class of case, and we feel that his suggestion that in such cases the examiner should be permitted to communicate the fact to the proposer is one well worth considering. We believe in practice this is frequently done, although the general rule is that the examiner should not communicate any opinions as to his examination to the proposer. This question and similar problems of the relation of the medical examiner to the proposer have been recently debated in our columns, and offer a useful subject for discussion at the Assurance Medical Society.

Annotations.

"Ne quid nimis."

THE NEW ORLEANS SESSION OF THE AMERICAN MEDICAL ASSOCIATION.

After an interval of 17 years the American Medical Association is again holding its annual gathering at New Orleans, with 435,000 inhabitants, the southernmost centre of the great constituency. Fifty-three constituent associations send their representatives to this gathering, the numbers varying from 11 for New York and eight for Illinois down to one each for the smaller States. The 15 scientific Sections of the Association send one delegate each, as do also the medical services of the Army and Navy and the Public Health Service. The House of Delegates meets on Monday, April 26th, the general meeting of the Scientific Assembly on the evening of Tuesday, and the Sections from the following Wednesday to Friday. A number of foreign visitors will be present, including, from this country, Sir Humphry Rolleston, who is announced to give the opening address at one of the sessions of the Section of Medicine, Mr. H. J. Waring, Dr. Norman Walker, and Dr. A. H. Freeland Barbour, who contributes a lantern-demonstration on the sectional anatomy of labour. Professor Victor Morax, of Paris, is to address the Section of Ophthalmology on the extraction of cataract in glaucoma. Accredited physicians from foreign countries are registered at the session as "invited guests" and enjoy all the privileges of membership. These sessional meetings afford great educational opportunities. This year's delegates will have the opportunity of studying the sanitary revolution which has taken place in the "Crescent City" since 1903. Lying with the prodigious Mississippi at its front and Lake Pontchartrain at its back, New Orleans is, to the extent of one-third at least, at or below the mean level of the lake with another third or so below high-tide level. Prior to 1900 the soil of the city was saturated practically to the surface, and up to 1908 there were no sewers. A complete drainage system, carried out at a cost of 32 million dollars, has now been completed, by which the sewage is pumped into the Mississippi River, where it is immediately carried away in the muddy flow. Effective drainage is provided even under meteorological conditions which include a possible rainfall of 3½ inches in an hour or 9 inches between dawn and sunset. The effects on mortality statistics of this colossal installation have fully justified the outlay. In the decade 1880–89 the death-rate from malaria was 156 per 100,000, and from typhoid 21; last year these figures stood at 4 and 13 respectively; the death-rate from all causes having fallen in the same period from 28·6 to 18·2. Some of the credit may be attributed to the treatment of the water-supply by a new continuous process, the raw water from the river passing first through a grit chamber, being then mixed with the appropriate quantity of ferrous sulphate and milk of lime, thereafter sedimented, and finally sterilised by chlorination. Other recent improvements, such as almost complete rat-proofing of buildings, will conduce to make the stay of the delegates pleasant, especially as the mean temperature to be expected during the congress is 66° F. The special train with sleeping cars bringing delegates from Chicago will be parked so as to allow of the cars being used as sleeping quarters. The s.s. *Comas* of the Morgan line will make a special trip from New York to the Gulf of Mexico on April 21st. Other organisations such as the Air Service Medical Association of U.S., the American Radium Society, the Association of Military Surgeons of U.S., and the Medical Veterans of the World War will take the opportunity of meeting during the assembly. The extensive commercial exhibit, arranged by Mr. Will C. Braun, of 535, North Dearborn-street, Chicago, will be in the Josephine Hutchinson Memorial Building. A carnival ball, a fête champêtre, and a tournament of the American Medical Golf Association complete the attractions, which will be added to by the beauties of the old French quarter, dating back to the foundation by Bienville in 1718 and the location here of the French Government of Louisiana. The New Orleans School of Medicine was started in 1834, and the Tulane Hospital of the University likes to be reminded of the fact that it was in 1917 the first base hospital in the Southern States to be fully organised.

THE TREATMENT OF BILHARZIA DISEASE.

IN his paper on the Treatment of Bilharzia Disease with Tartar Emetic in South Africa, which appears in our present issue, Dr. F. G. Cawston confirms the work already done by J. B. Christopherson[1] in Egypt and by G. C. Low and H. B. G. Newham[2] in London on this important subject. His work was embodied in the Streatfeild Lecture, delivered under the auspices of the Streatfeild Research Scholarship, a recent foundation at the Royal Colleges of Physicians and Surgeons. His results bear out the beneficial results obtained by the authors just mentioned, and it would now seem as if antimony was a real specific for such infections. It is questionable, however, if the doses given by Cawston are large enough, some of his cases only receiving a total quantity of 9 or 10 gr. of tartar emetic in all. Christopherson and Low, on the other hand, believe that at least 20 gr., if not 30 gr., should be the total maximum dose, and their carefully recorded results would tend to show that such a dosage is the correct one. In Cawston's conclusions he states that a dose of 1½ gr. is sufficiently large to administer to any patient at one dose, but there is no reason why 2 or 2½ gr. even should not be given to any healthy adult. The authorities mentioned begin usually with ½ gr. for the first dose and then raise the quantity gradually up to 2½ gr., noting carefully any signs of idiosyncrasy that may occur. Cawston's idea that the rise of temperature which so often occurs after antimony injections is due to sepsis or exposure to cold will not hold. We hope that people who give such injections are too careful to introduce sepsis, and rigors may follow even though the patient is lying in a warm bed. It is more probable that the reaction is due to something in the distilled water, because if this is freshly distilled before each injection such rises of temperature are much less frequent. Other common symptoms, such as cough, tightness in the chest, vomiting, and a tendency to syncope, have also been met with by Cawston, and to prevent these he suggests giving codeia before the injections. Skin rashes are far from common, and the fact of blisters occurring along the line of the vein looks as if there had been a leakage of the salt into the tissues. It would be interesting if the after-histories of these South African cases could be followed up. In an endemic zone the chances of reinfection must always be remembered, of course, but Low and Newham's English-treated cases have all remained cured with no signs of any relapse.

THE TREATMENT AND CARE OF SANE EPILEPTIC CHILDREN.

No therapeutic problem is calculated to awaken greater interest in its successful solution than that of the treatment of the epilepsies. One reason why this treatment has scarcely progressed beyond the symptomatic stage is ignorance of the actual pathogenesis of the condition no less than of the identity or otherwise of the idiopathic and secondary varieties. On the one hand there is the clear case of cortical irritation from organic disease, of Jacksonian epilepsy from tumours, wounds, or vascular disease of the motor area; but difficulties at once commence with the occurrence of generalised epileptic attacks from frontal, parietal, temporal, or occipital wounds indifferently, suggesting that the stability of the cortex is somehow lowered as a whole by a lesion in any part of its extent. When, however, the numerous cases of cerebral trauma free of any epileptic disturbance are borne in mind, we are reduced to the supposition of some predisposing factor for the epileptic cases and find ourselves once more in the futile realm of conjecture. Serious attempts have been made to raise into importance a psychogenic element, more particularly in war epilepsy, and there can be no doubt not only that genuine epileptiform attacks may have their origin in a disordered psyche, but also that treatment along psychological lines may command success.

Notwithstanding the assertions of the psychological extremist such cases are far indeed from filling the whole bill; they constitute only a small minority, how small may be gauged when we bear in mind the epilepsies of uræmia and eclampsia, of alcohol and neurosyphilis, of vascular disease such as the Stokes-Adam syndrome, and when we consider more particularly the epilepsy of infants and children. Variety of causation militates against acceptance of any unifying theory of the disease, but, unfortunately, it renders equally remote the possibility of any discovery of a specific for its treatment, so that the selection of a suitable environment and the adoption of a suitable nerve sedative too often represent the therapeutic endeavour. What can be accomplished has been outlined in a brochure[1] by Dr. J. Tylor Fox, who has been for some 18 months medical superintendent of the colony at Lingfield. His impressions and observations are based on the examination of some 167 patients not yet past their sixteenth birthday. He begins by emphasising the unsuitability of the majority of English homes for epileptic children whose abnormality constitutes a bar to their association with other children, when the tendency grows to keep them more and more within doors. They are not wanted at church, chapel, or Sunday school, at picture shows or other entertainments. Besides, the parents often manifest signs of mental instability. On the other hand, the accepted essentials of the colony are an outdoor life, open windows, daily bath, and a suitable diet. The facts that the fits are ordinary occurrences and call for no special comment, while the teachers, nurses, and attendants in the institution strive to combine a firm discipline with sympathetic understanding, are positive advantages outweighing the staple objection to the system that it eliminates the idea of family relationships and intimacy from the child's life.

[2] THE LANCET, 1919, ii., 633.

[1] The Care of Sane Epileptic Children. By J. Tylor Fox, M.A., M.D. London: Bale and Sons. 1920. Pp. 40. Price 1s. 6d.

Dr. Fox discusses fully the question of drug treatment. It has been claimed that any good bromide may do by controlling fits is more than balanced by the harm it does in other directions, and that it exercises a harmful effect upon the higher mental functions, but such strictures are probably based on the administration of immoderate doses. The old idea of pushing bromide until the fit habit is broken is not justifiable in view of the fact that arrest of the fits does not exclude the possibility of their reappearance. It may not always be desirable to repress epileptic discharges. Dr. Fox is satisfied there is a small but definite class of epileptic patients who become depressed and irritable for hours or days before a fit, and in whom a major attack "clears the air," and he believes the sound treatment in such cases is to reduce or withdraw whatever routine dose the patient is already taking. His general conclusion is that bromide medication is not by any means the most important factor in the treatment of epileptics on a colony, though the greater number of his cases receive on the average about 20 gr. daily. If bromide is going to lessen or arrest fits it will do so in a few weeks, and if it has not done so in some months the drug may gradually be withdrawn without ill-effect. Borax, as judged by the records of some 69 cases, certainly tends to reduce the frequency of fits, a reduction the more remarkable as in very many cases the drug was given at a time when the attacks were increasing in number. Belladonna and digitalis do not appear to exert any useful influence on fit-incidence, nor do strychnine and calcium lactate. Dr. Fox supplies tables containing valuable information of the general effect of colony life on fits and on mental development. We take pleasure in recommending the pamphlet to all who are concerned with the treatment of epilepsy.

SIMULATION AMONG PRISONERS OF WAR.

Commenting on Professor Pellegrini's article on this subject, which recently received notice in THE LANCET,[1] Dr. Luigi Castaldi,[2] of Florence, gives an interesting account of simulation as practised by Italian officers interned in Austria-Hungary. He points out that the principal difference between simulation in Austro-Hungarian and German camps was due to the fact that while in Germany the only advantage which the successful simulator could obtain was to be transferred to hospital, in Austria-Hungary he had a good prospect of repatriation. This was the reason why cases of simulation in German prison camps were only sporadic, whereas in Austria-Hungary the practice was extremely prevalent. Dr. Castaldi does not hesitate to affirm that 80 to 90 per cent. of the officers who were repatriated from the camps in Austria-Hungary were simulators, only a very small minority having really severe wounds or tuberculosis. Among the private soldiers, on the other hand, with whom tuberculosis and malnutrition were very rife and the mortality very high, simulation was rare, and the great majority of those repatriated were really seriously ill. It was noteworthy that while the diseases simulated in Germany, according to Pellegrini, were all mild, transient, and acute, such as jaundice, œdema, and pseudo-elephantiasis, in Austro-Hungary those diseases were simulated which produced a more or less permanent disability, such as tuberculosis, atrophy of a limb, neurasthenia, and mental disease. Simulation of tuberculosis was effected in various ways—e.g., by injection of air into the skin of the supra-clavicular region so as to give rise to a tympanitic note and crepitations on auscultation, prolonged fasting, and the use of certain drugs, such as thyroid extract in large doses and purgatives, to produce emaciation, ingestion of large doses of iodide of potassium to make the vesicular breathing rough at the apices, smoking of cigarettes containing sulphur, cotton, or straw to produce râles, and the substitution of the sputum of an actually tuberculous patient for which a large sum was often paid. In a few instances diabetes or nephritis was simulated by introduction of glucose or albumin into the bladder or merely into the meatus or beneath the foreskin. Although the simulators were willing to undergo a considerable amount of discomfort to secure their purpose, Dr. Castaldi did not see or hear of any case of suicide or auto-mutilation.

COÖRDINATION OF RESEARCH AT THE MIDDLESEX HOSPITAL.

IT is in our opinion a wise proposal on the part of the authorities of the Middlesex Hospital to amalgamate the Cancer Research Department and the *Bland-Sutton Institute of Pathology* with the Medical School. The object of the proposal, which has just been considered by the Court of Governors, is to bring the various departments concerned in research, both in regard to cancer and other medical problems, into closer coöperation so as to avoid anything like overlapping, and to economise in regard to staff and laboratory accommodation. Closer coördination between those working at these problems would thus be insured. Even within the walls of a single institution it is possible for waste of effort to occur unless some such scheme is carefully worked out. Another advantage which is likely to accrue is that closer relations will be set up between the clinical and the laboratory aspects of the work of the hospital, which should be fruitful in two ways; research would be well directed, and the scientific results would be applicable to the actual diagnosis and treatment of disease, especially of cancer, for which this hospital offers such a valuable field. The recent establishment of university chairs in pathology, physiology, physics, and radiology at this institution should give a great impetus to the application of these branches of pure science to medical problems, especially under the conditions suggested in the new proposals.

AN EXTENDED SCHOOL MEDICAL SERVICE.

A white book,[1] recently issued by the Board of Education, applies to the whole public educational service arrangements similar to those already existing under the more progressive authorities. The extension of the compulsory limit of education beyond the age of 14 years, a change involved in the Fisher Bill of 1918, made this step inevitable. All secondary, continuation, and special schools are now included in the scheme. The minimum age of admission to special schools is reduced from 5 years to 2. Under this heading the deaf-mute will benefit most, as the earlier he is taken in hand the better. With this exception it is to be hoped that local authorities will get sufficient nursery schools going for healthy children before tackling special schools at this age, when it will be found that the blind and otherwise physically defective child will fare very well in the ordinary nursery school. The infinitesimal numbers in the small area covered by a nursery school do not warrant a special school, nor is institutional life for these youngsters advisable; their presence also would educate the healthy child in sympathy and tolerance. Rural authorities will still look in vain for guidance in the regulations which are being framed entirely for urban areas, where problems have quite a different complexion. They specially need help in deciding how the mentally defective and cripple children in scattered areas are to be collected and taught. The possibility of a continuous medical record for the school child is brought nearer by the regulations. The ideal to be aimed at is a dossier for each child, a single card accompanying it from the nursery to the elementary school and from there to the secondary or continuation school. We hope that the process of boiling down the multifarious documents at present relating to one child may not devolve upon the unfortunate school medical officer, already overburdened by schedules and cards. Too many routine inspections make it impossible for him to become properly acquainted with the general hygienic conditions of the schools in which he and the children spend so much of their lives, and in which, if time allowed, he could carry on inquiries of lasting value to educational life. As things are, he is generally a whole-time worker condemned to a dull routine in order to compile the tables demanded by the Board of Education.

MEDICAL RESEARCH IN INDIA.

IT is probable that few people outside the Indian Medical Service are aware of the treatment that scientific medical investigators have received in the past from the high officials on whom favour or fortune has placed the responsibility for governing India. Fortunately, at the present moment matters have reached a far more satisfactory point, and the value of medical research is now admitted by many administrators in India. Formerly discouragements of all kinds were placed in the way of the investigator, and many valuable researches have been carried out at the worker's own expense, and in spite of official obstacles purposely placed in his way. In the recently issued special number of the *Indian Journal of Medical Research*, containing the papers and addresses read before the Sixth Annual Indian Science Congress, held at Bombay last year, two instances were mentioned which illustrate to some extent the official attitude of the past towards medical research in India.

The first of these was given by Lieutenant-Colonel Sir Leonard Rogers, I.M.S., President of the Congress, in his opening address. He relates how Mr. N. C. Macnamara, I.M.S. (there were no military titles in those days), had been engaged for a number of years in a special study of cholera in India, particularly in Calcutta; how he had published his views, quite novel at the time, that this disease was spread by water contaminated with the stools of cholera patients; and how also he had clearly indicated that the causative organism would be found in the evacuations of the sick. Some time later, while at home on leave, he studied the then young science of bacteriology, *at his own expense*, with a view to further investigations on cholera when he returned to India. Having thus qualified himself to undertake the search for the specific organism of cholera, he applied to the India Office for facilities to pursue his investigations on his return to duty. It is almost incredible, but nevertheless the fact, that the India Office absolutely refused to give him the required facilities, although within a year they granted them and other privileges as well to a German bacteriologist who wished to make a special investigation of cholera in India. This German bacteriologist in the meantime discovered the cholera vibrio while working in Egypt. If Macnamara had been given the facilities when he asked for them it is almost certain that he would have isolated the cholera organism. This instance, Sir Leonard Rogers remarked, was typical of the way in which scientific investigators in India were treated not so very long ago. Mr. Macnamara, who died at the close of last year at the advanced age of 86, retired from the Indian Medical Service in 1876, was elected to the staff of the Westminster Hospital, and became Vice-President of the Royal College of Surgeons of England.

The second instance, a personal one, was related by Lieutenant-Colonel W. Glen Liston, I.M.S., in his address as President of the Medical Research Section of the Bombay Congress. It was to the effect that shortly after joining the Indian Medical Service he became deeply impressed as to the connexion of insects with certain diseases, and in consequence he studied entomology. Later he was transferred to a very malarious station in medical charge of a regiment and a small civil surgeoncy. Continuing his entomological studies there, he discovered a number of new species of anophelines, investigating their habits and locating their breeding-places. This information he embodied in an official report in which he made recommendations for the destruction of the malaria-carrying mosquitoes and for "training" the river which passed through the cantonment. He also suggested that a part of the local hospital should be protected against access of these insects by wire gauze to prevent them biting malaria patients and thus spreading the disease. To his surprise and chagrin, no notice at all was taken of his report, and it was not until a long time afterwards, when he met the principal medical officer, that he asked him as to the fate of the aforesaid report. He was told that, as his proposals were too costly to be accepted, the report had been ignored altogether. He was also informed that when the P.M.O.'s head clerk inquired what he was to do with the report the answer was "file it," which was tantamount to burying it for ever. Thus an opportunity for converting an unhealthy station into a healthy one was lost, and some risk was run of the Indian Medical Service losing a competent investigator, who, after the chilling reception of his first report, might have relinquished scientific investigation for some more popular and remunerative branch of medicine. Fortunately, in this instance no great harm was done in this direction, for Colonel Glen Liston stuck manfully to scientific research, and subsequently it was largely through his experimental investigations that the ætiology of bubonic plague was placed on an unassailable basis.

Happily, as has been said already, medical research in India is now more appreciated; the neglect of the past is being remedied. At the present time there are at least six medical institutes for scientific research in one or another part of India manned by members of the Indian Medical Service. Two schools of tropical medicine are being developed, one in Calcutta and the other in Bombay. The Indian Government has established a fund for medical research, which has already financed a number of investigations which otherwise could not have been carried out. The present, then, may be regarded as offering to research workers favourable opportunities in India for solving some of the important problems which have been awaiting solution. Medical research in India may now be said to be on the upgrade after many years of discouragement.

ASYLUMS MEDICAL STAFF.

THE Board of Control, in a circular (No. 560), dated March 3rd, addressed to the visiting committees of county and borough asylums, suggests many improvements in the status of the asylums medical service. Increased salaries, along with liberty to marry and to live outside the ring-fence, are designed to make the lot of the medical officer a happier one, while restriction in the number of recent cases under his individual care and the granting of study-leave are to increase the efficiency of his work and his interest in it. If the welfare, treatment, and recovery of patients is not to be jeopardised, and the study of mental diseases is not to lag behind that of other branches of medicine, the Board of Control urges upon asylum committees the need of initiating measures to maintain progress, and offers to confer with them as to the best lines of carrying the measures through.

THE MEDICAL AND DENTAL REGISTERS.

THE total number of names on the Medical Register on the last day of the year 1919 was 44,522, being 596 more than a twelvemonth previously. 1322 names were added by registration during the year, 34 were restored, and 760 removed, 643 on evidence of death. We miss a record of the proportion of men and women practitioners, which would be of general interest. 1500 names appear in the Colonial List and 165 names in the Foreign List. The professional colleges of Alberta and the North-West Territories of Canada now figure among the bodies granting degrees registrable in this country. The Dentists' Register contains 5455 names, being 112 fewer than a year ago, and only a bare 315 more than in the year 1913. Among the qualifications entitling certain colonial and foreign dentists to enrolment appear for the first time the D.D.S. of Dalhousie and of Laval (curiously mis spelled Naval) University, the L.D.S. of the Royal College of Dental Surgeons of Ontario, and the Royal Swedish Dental Diploma. The Medical and Dental Students' Register contains the names of 3420 medical students enrolled during the year 1919. 1375 in England, 1387 in Scotland, and 658 in Ireland. Comparable figures for 1913, the last pre war year, were 650 + 536 + 294 = 1480. The entries of dental students for the years 1913 and 1919 are 361 and 612 respectively. It should be noted, however, that from 1916–18 the dental entry barely exceeded an average of 150 a year. Taken as a whole an inspection of these registers assures a sufficiency of recruits to the medical and dental professions, but for the nonce the shortage of registered dentists remains unrelieved.

THERE are 155,729 persons on the books of the Bristol Insurance Committee.

ARRANGEMENTS have been made for applying the Schick test and actively immunising against diphtheria the susceptible children in 100 public schools of New York City.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Remuneration for Public Medical Services.

A LARGELY attended meeting of the Poor-law medical officers of the north western counties was held recently at Clones, county Monaghan, at which several resolutions dealing with the remuneration for certain public services were unanimously passed. In the first place, the meeting reiterated the demands of the Irish Medical Committee regarding the minimum salaries that should be accepted for Poor-law appointments and for Poor-law locum tenens duty. A further resolution dealt with a subject to which, up to the present, medical men have paid too little attention—the salaries paid to Poor law medical officers in their capacity as medical officers of health. These salaries have hitherto been so small as to be almost negligible: they range from £5 to £25 a year, the average being about £15. It is now demanded that the minimum salary for rural districts should be £50 and for urban districts £75. Poor-law medical officers, by virtue of their office, are entitled to the office of registrar of births, deaths, and marriages The emoluments are trifling and in many cases medical officers have thrown up these appointments. The Clones meeting demanded a uniform fee of 2*s*. 6*d*. per entry. A more important, and an entirely just, demand is that the State should pay a fee of 5*s*. for each death certificate issued by a medical man. It is out of all reason that this important work should be thrown on the shoulders of the profession without remuneration.

Tuberculosis Sanatoriums for Belfast and District.

At an adjourned meeting of the City Council of Belfast, held recently, it was reported that, in response to a request by the Tuberculosis Committee, the Ulster Medical Society and the Ulster Branch of the British Medical Association, Mr. A. Fullerton, Mr Grimble, and Mr. T. S. Kirk had conferred with Sir Henry Gauvain, in reference to the proposal to develop Graymount as a sanatorium for the treatment of osseous tuberculosis of children. While agreeing that the establishment of such a sanatorium was necessary, they considered that a more suitable site should be procured outside the valley of the Lagan, on the county Down side of that river, which runs through the city of Belfast. In the meantime, until Sir Henry Gauvain reports, the whole matter is in abeyance, public opinion being decidedly against Graymount as a site. Another recommendation was to extend the accommodation of the Whiteabbey Sanatorium for Pulmonary Tuberculosis, which was strongly opposed by Dr. J. D. Williamson, chairman of the Public Health Committee. The cost of this extension, he said, would be anything from £15,000 to £20,000, and, he asked, had there been a commensurate amount of good accomplished for the money spent on tuberculosis in Belfast? His advice was to purchase land outside the Lagan Valley on which to erect a sanatorium worthy of the city of Belfast and not to spend more money on adding to the sanatorium at Whiteabbey, where, he added, "every one knew that cases of acute pulmonary tuberculosis had not a fair chance of recovery." He would not scrap Whiteabbey Sanatorium, but he would use it for advanced cases of pulmonary tuberculosis—as a home for the dying. The council, however, adopted the recommendation authorising the Tuberculosis Committee to take the necessary steps for the preparation of plans and estimates for the Whiteabbey Sanatorium extension.

The Down County Council have purchased a house and grounds on the east side of Belfast Lough called Craigavon, about three miles from the centre of the city of Belfast, for a consumption sanatorium. Against this action the local residents are loudly protesting, and at the half yearly meeting of the Castlereagh rural council all the members expressed themselves as strongly opposed to the county council's proposal to take Craigavon on the ground that the site was low-lying and unsuitable, and that, throughout county

Down, there were higher levels that would be of greater advantage. An inquiry into the question is being held, and the Castlereagh rural council instructed their solicitor, with a deputation from that body, to appear at the inquiry and to oppose the proposal of the Down County Council. In one of the Belfast papers Mrs. Green, the widow of Mr. Forster Green, who established the "Forster Green Hospital for Consumption," states that many years ago, when her husband considered the suitability of several places for a tuberculosis sanatorium—even as far back as 30 years ago—Fortbreda, high and sheltered, was felt to be infinitely better than any site near the shores of Belfast Lough. She entirely agrees with those who say that either side of Belfast Lough is unsuitable for a tuberculosis sanatorium.

A City Bacteriologist.

The City of Belfast Municipal Council have decided that, pending the erection of a municipal laboratory, arrangements shall be made for carrying on the general bacteriological work of the corporation in the Central Tuberculosis Institute, and that a qualified bacteriologist, to devote his whole time to the duties of the office, shall be appointed. The proposed salary is £700 a year, rising by £50 increments to £900, and a whole-time laboratory attendant is to receive £250 a year. It was also recommended that Professor St. Clair Symmers, whose appointment as bacteriologist expired on March 31st, should be retained in that position for a further term of one year at a salary of £350.

April 12th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The First Recorded Case of Aleppo Boil in France.

M. Ravaut has reported to the Academy of Medicine a case of Aleppo boil contracted in France. It occurred in the Pyrenean district in a young girl who had never been out of France. She had been subject to bites by mosquitoes every summer, and two of the bites were followed by nodules, one on the nose and one under the right eye. The lesions had been present for a year and had resisted all treatment. Clinical diagnosis was almost impossible, as neither the induration nor the classical furunculosis was present. Microscopic examination, however, showed by the presence of innumerable Leishman's bodies that the nodule was an oriental sore. Treatment by novarsenobenzol was immediately followed by shrinkage of the lesions. The case is interesting since it is the first reported proof of the propagation of this infection in France; the germ must have been introduced by the Kabyles or by colonials working in the vineyards of the district. Other cases will almost certainly be discovered if a systematic search is undertaken; examinations should be made on small portions of tissue crushed between two slides and not on the serous secretion.

The Eight-hour Day and Hospital Staffs.

Physicians and surgeons are complaining that the institution of the eight-hour day among hospital staffs has totally upset the nursing, and on behalf of their colleagues MM. Cuneo and Sergent have made a protest on this subject to M. Mesurier, director of the Assistance Publique in Paris and of the supervisory council of this administration. The rounds of the honorary staff are usually made from 9 A.M. The change of shift following shortly after their visit results in the treatment being given by nurses who, not having been in attendance on the round, cannot carry it out as efficiently as if they had themselves heard the precise details ordered by the chief. To quote the protest of MM. Cuneo and Sergent "the change of personnel produced by the law of an eight-hour day is very prejudicial to the patients; it would seem as though the law should never have been applied to hospital staffs." Questioned on this subject, M. Mesurier said that it was impossible to discuss the eight-hour day, which is applicable to all municipal employees and consequently to the hospital staffs, who could not be treated differently. The way to avoid the danger emphasised in the memorandum of MM. Cuneo and Sergent is to change the method of application of the law and to make it accord with the interests of the patients. M. Mesurier promised to give the reform his immediate consideration and has no doubt that a new adjustment of the rules will give satisfaction to all parties. This controversy having been published in the press, the union of hospital attendants has issued a protest, in which it accuses the doctors of not having made efforts to adapt themselves to the consequences of the law and of beginning their rounds too late. It is alleged that some of them do not arrive at hospital till 11 o'clock, after having disposed of their private patients. When these clinicians have seen some 100 patients between 11 and 12, the shift which has been on duty since 6 A.M. has no time to complete the treatment and dressings ordered before going off duty, and these are left to the next shift, which has, perforce, to receive its instructions at second-hand. This statement on the part of the hospital staffs seems much exaggerated, and it is only the exceptional cases which have been quoted by them. In practice, when the visiting doctor arrives late, his assistants have already examined the patients and have prescribed for most of them so as to have to refer to their chief for a decision only on new or serious cases. Besides, all the dressings are done in the hospitals by the assistants themselves, not by attendants or nurses.

The Campaign against Cancer.

M. Le Troquer has made a proposal to the Municipal Council of Paris, designed to develop the fight against cancer, which is still on the increase. While in 1910 3073 cases were notified by doctors, last year there were 3619. Nevertheless, M. Le Troquer estimates that, according to results already obtained by numerous scientists, the certain cure of cancer will be realised in the near future by means of radium. Unfortunately radiotherapy has hitherto been confined to the private practice of a few specialists, mainly resident in Paris. Apart from these, there are other medical men—certainly becoming more numerous—who possess of this precious substance a fragment so small as to have little therapeutic value. Obviously, at 800,000 francs a gramme radium is not available for many purses. The Assistance Publique is not in a position to afford this special treatment to the poor. Dr. Regaud and one of his colleagues in the Pasteur laboratories are the only ones who have begun to treat cancer patients in Paris hospitals by radium. In other countries, on the contrary, radiotherapy has developed considerably. For this reason M. Le Troquer asks for the institution of an autonomous hospital dispensary, in connexion with the Radium Institute of the University of Paris, which shall have the possession of 2½ grammes of radium, bought by means of a loan of 2½ million francs, for which M. Le Troquer also appeals. The hospital would be constructed near Paris on a site now available owing to the demolition of fortifications.

April 10th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Effect of Altitude on the Blood.

Dr. Voicu, a Roumanian pilot, formerly a medical practitioner, has been studying the effects of a high altitude on the blood, and for this purpose has analysed the amount of iron contained in the organs of soldiers and animals in the highest parts of the Carpathian mountains, as compared with control men and animals. Even after a short stay in the mountains a decided reaction is noticed, since liver and blood and spleen become rich in iron. The explanation is probably that reserve depôts are opened and more hæmoglobin is passed into the blood; since this is used up more rapidly more iron is deposited in the liver. After the second or third week the hæmopoietic apparatus ceases its over-production and the liver gives up its iron to the blood. As a result the iron content of the blood gradually increases, while that of the liver first rises and then falls. This observation is in perfect accord with the result of blood counts made on pilot pupils, who during instruction time are spending, so to say, several months in the air at heights equal to high altitudes. The chief stimulant is probably the rarefied air, but it is likely that radio activity, which is present to a marked degree in the mountains, plays a prominent part.

The Toxicity of Cresols

In the absence of modern and up-to-date disinfectants recourse is had to cresols, which are widely used here instead of the modern lysoform preparations. Dr. Vamossy examined the effects on a number of animals (cats, rabbits, mice, frogs) of the three isomeric cresols, and found that all the three behaved differently. Paracresol is decidedly more poisonous than carbolic acid for both carnivorous and herbivorous warm-blooded animals; orthocresol is equal in toxicity to carbolic acid, as described by Dr. Tollens in 1901, but metacresol is less toxic. A number of crude and saponified samples of cresol on the market were also examined. Contrary to the usual statements, they gave rise to the same symptoms in about the same dosage as carbolic acid and some of the crude samples proved even more toxic. The presence of soap does not seem to diminish the intensity of action, and the same is true for carbolic acid, since the latter, plus soap, introduced into the stomach of an animal, kills just as rapidly as carbolic acid alone.

The Practice of Medicine in Albania

Dr. Vulcan practised during the last four years of the war in the Mohammedan part of Albania and recently stated before the Medical Society of Nagy Szeben that practice in Albania is attended with great difficulties in consequence of social and religious customs. These, with the dense ignorance and extreme poverty of the mass of the people, are responsible for the widespread epidemics which prevail and which have baffled all the efforts of the Austro-Hungarian Government for their suppression. There is no scientific system of native medicine. Herb doctors, known as "hodzsas," combine with their medical practice the use of charms and incantations, with offerings to the gods. Superstitions and astrology are credited and much practised. Surgery is in the hands of unskilled barbers. The condition of women is particularly deplorable. Even the daughters and wives of the so-called cultured classes can never see a male physician, but must be treated through the medium of ignorant midwives. The intermarriage of near relatives and child marriages are an unfailing source of evil. Girls of 12 to 13 years are known to become mothers. Of course, an increasing population under these physical conditions cannot be a healthy and vigorous one. The mortality is great in consequence of the grinding poverty and bad housing. The nutrition is very poor; pork fat is not used, herbaceous oils alone being allowed. The hospitals established of late years may perhaps improve the high mortality rate.

Poisoning with Methyl Alcohol

Owing to the high price of pure refined alcohol unscrupulous brandy dealers have recently sold methyl alcohol, with the result that several of the consumers have died, or have suffered from severe nervous disorders, particularly optic neuritis. In this connexion Dr. Pollak recently gave an address on the comparative toxicity of alcohols. He said that all the alcohols of the methyl series are toxic, but in an ascending scale from methyl alcohol to amyl. Methyl alcohol, or wood alcohol, as it is called here, is cumulative in its effect, the others are not. This seems to be due to the fact that one of the most important effects of methyl alcohol is a great retardation of oxidisation. Methyl alcohol remains more or less unchanged when in contact with the tissues, and as a consequence continues to exert its influence. According to some authorities methyl alcohol partly metabolises into formaldehyde and formic acid, which would account for its toxic effects. In recent years, owing to the making of odourless wood alcohol, there has been much more abuse than has come to light. Some cases have even been reported in which pharmacists have used it in tinctures. It is surprising, said Dr. Pollak, that more peripheral neuritis has not been reported from its use. It seems probable, however, that death comes so soon that peripheral neuritis has not time to develop. It acts specially on the ganglion cells of the retina, but also on other important cells of the central nervous system.

Nagyvarad, March 24th.

TUBERCULOSIS

Tuberculosis as a Factor in Depopulation

A RECENT number of the *Paris Médical* gives an interesting abstract by Dr. Perrin, professor in the Faculty of Medicine at Nancy, of an investigation made by him years ago into the influence of a tuberculous stock on the upward or downward trend of population. Dr. Perrin, in the course of his duties at the hospital at Nancy, made inquiry into the histories of 1000 families, all of the working classes. Of these families, 500 had one or other parent tuberculous, while in each of the other 500 families both parents were free from tuberculosis, the visit to the hospital being on account of non-tuberculous disease. The families were in no other way selected, and were a consecutive series in their attendance at the hospital. Dr. Perrin further states that in their environment, habitations, overcrowding, exposure to infectious disease, alcoholism, venereal disease, and gastro-enteritis, and also in their years of married life, the two groups were exactly comparable. At the same time it must be pointed out that their economic circumstances would require very careful investigation before their similarity can be unreservedly accepted; on this Dr. Perrin's summary in the journal in question does not throw sufficient light.

The first point deduced from Dr. Perrin's data is that, whatever the reason may be, the non-tuberculous group is markedly more prolific than the tuberculous group. Then, not only are the children of the non-tuberculous more abundant, they are also less vulnerable to disease in general, and less affected by tuberculosis in particular. The proportion of healthy children among the non-tuberculous families was double that among the tuberculous. The difference was, in fact, such that a population consisting of households infected with tuberculosis would tend steadily to diminish, while a population composed entirely of healthy non-tuberculous families would tend to double itself from one generation to the next. In all this there is, of course, no valid argument for the policy of leaving the extirpation of the disease to natural laws. Assuming the accuracy of Dr. Perrin's standards for the comparison between the two sets of families, there is nothing but encouragement to the social worker in the view that his human effort towards the elimination of tuberculosis is in the same direction as, and not opposed to, the natural history of the disease itself. These data are an indication of the need for caution in associating a downward curve in the mortality from tuberculosis with particular preventive or curative measures.

The Effect of Tuberculosis on the Length of Life

In the *Statistical Bulletin* of the Metropolitan Life Insurance Company for February a report is published of the effect of tuberculosis on the length of life of industrial policy-holders. The disease reduces the expectation of life of white males by nearly three and a half, and of coloured males by approximately five years. Under the prevailing rates of tuberculosis mortality, the expectation of life of the industrial white male at birth is 46 years, and of the coloured male only 37 years. It is calculated that the eradication of tuberculosis would add as much to the life-span as has resulted from all the sanitary improvements of the last 25 years. The tuberculosis mortality among wage-earners in 1919 shows a favourable decline, equivalent to a drop of 33 per cent. below the figure for 1911. This achievement is attributed to public health and educational work during the past 30 years and to the intensive health conservation work of this company on behalf of its policy-holders. It is also interesting to note that, in the experience of this company, the influenza of 1918 had little effect on the incidence of tuberculosis.

Friedmann's Turtle Vaccine.

The committee officially appointed to investigate the value of Friedmann's remedy has already sat four times. At the first sitting the measures necessary for a thorough investigation of the remedy were discussed. Professor Friedmann attended the second sitting, and at the end of the third sitting he had consented to submitting his remedy to various tests. At the fourth sitting, which was presided over by Professor Uhlenhuth, subcommittees were appointed, one with the task of experimental biological investigations, another with that of clinical investigations, medical and surgical. A committee was also appointed to sift the literature of the subject and to collect hitherto unpublished records. Many well-known names appear on the main committee, including those of Professor Kraus of Berlin, Professor Kruse of Leipzig, and Professor Braun. In a letter to the *Münchener medizinische Wochenschrift* for March 12th, Professor Friedmann, referring to the liberation of his remedy for wholesale testing, appeals to his colleagues to follow strictly his indications and technique, and to fill in certain forms to be forwarded to Berlin with a view to subsequent statistical analyses.

The Campaign against Tuberculosis in Canada.

The province of Quebec is about to embark on an active campaign to eradicate tuberculosis. As elsewhere, Quebec is realising that tuberculosis causes the most striking of all losses of productive population. Toward this end the Superior Board of Health of Quebec has recently appointed a special committee of four medical men competent in public health work. Dr. J. A. Beaudouin is to act as secretary of this committee, the other members of which are Drs. J. E. Laberge, R. Paquin, and E. M. Desaulniers. They will make an exhaustive study of the problem of tuberculosis in the province before applying the knowledge gained in a province-wide campaign. The Quebec Government and the Federal Government will be asked to assist, and boards of trade, the pulpits, platform, and public press will be swung into line to make the campaign a complete success.

A new sanatorium for the treatment of tuberculosis cases is being constructed at Keith in Alberta. The initial capacity is for 175 cases, increasing to 350 when all units are completed.

Annual Reports.

Much of the thirteenth annual report of the *King Edward VII. Sanatorium, Midhurst*, is devoted to bringing up to date the statistical analyses previously published by Dr. N. D. Bardswell. In April, 1919, a highly trained head gardener was appointed to instruct patients in their work. All physically fit for light gardening have shown a remarkable enthusiasm and have gained much useful knowledge. Of the 301 cases analysed, 69 were discharged with the disease arrested, 141 with health much improved, 48 improved, and 43 stationary or worse. Of the 305 throats examined 281 were normal, 24 diseased. The report does not give much information as to modern methods of treatment, such as actino-therapy and lung collapse, but a cheerful account of chicken-farming is added.

The fourteenth annual report of the *Trinidad Association for the Prevention and Treatment of Tuberculosis* contains useful statistical data. During the year 1918 the total number of deaths in the colony (pop. 379,165) from all forms of tuberculosis was 545—an increase of 40 deaths over the mortality of 1917. There was, however, no appreciable rise in the tuberculosis mortality till the last year of the war, and, as a table shows, the death-rate in 1918 was only 1·44 per 1000, as compared with 2·58 in the year 1905–6. This great reduction is regarded as the response to anti-tuberculosis propaganda. Since its establishment in 1905, the association has set itself three chief objectives. Of these, a dispensary for the gratuitous treatment of the disease and an educational campaign have been realised with marked success. But the third objective, a sanatorium for early cases, has not yet materialised. The association is, however, more than ever convinced of its absolute necessity, and an appeal is directed to the Government to help establish a tuberculosis sanatorium in some suitable place in the colony. It is pointed out that stamping out the disease can be effected at infinitely smaller cost than is possible in the United Kingdom. Without State aid it is evident that the tuberculous poor must inevitably provide ever-recurring sources of infection.

Tuberculosis in Foreign Journals.

The *American Review of Tuberculosis* for February opens with a sympathetic obituary notice of Sir William Osler by Dr. S. A. Knoff, who appends a bibliography of Osler's publications relating to tuberculosis. Though this runs nearly into two pages it is probably very incomplete. Dr. J. B. Rogers contributes a paper on Artificial Tuberculous Infection of Guinea-pigs through the Respiratory Route, and Dr. E. H. Funk a paper on Pulmonary Syphilis. The remaining three papers concern various aspects of accidental and artificial pneumothorax.—In the January issue of the same journal new light is thrown on an old subject by Dr. H. Sewall, who discusses the means for sorting out the tuberculous from that large group of patients seeking medical aid for a sense of "ill-defined misery." In conjunction with auscultatory and X ray signs indicative of slight tissue sclerosis about the hilum and upper bronchial radiations, the author has found blood-pressure measurements of inestimable value. The existence of occult tuberculosis is suggested when there is an abnormal lowering of the blood pressure, and when this lowering is progressive, on change from the supine to the erect posture. The author distinguishes between occult and incipient, clinical pulmonary tuberculosis, associating the blood pressure phenomena described with the former only. Though hypotension may also be a feature of incipient clinical pulmonary tuberculosis, it is not characterised by a critical lowering of the blood pressure in the erect posture. In a paper on Complement Fixation, Dr. S. A. Petroff finds that this test in tuberculosis is more specific than the Wassermann test, but it is only one of the many links in the diagnostic chain. And it is a delicate link; to be reliable the test must be carried out by well-trained workers. Dr. Lawrason Brown and Dr. Homer L. Sampson contribute a valuable paper on the Early X Ray Diagnosis of Ulcerative Tuberculous Colitis. They have come to the conclusion that tuberculous colitis occurs far more frequently than is generally supposed to be the case, and that in the early stages the clinical picture may be of little aid in diagnosis. But if the X rays show hypermotility and spasm, or filling defects, and pulmonary tuberculosis exists, then tuberculosis of the colon also may be diagnosed with certainty. Illustrative of the high standard of the Trudeau Sanatorium are the authors' final remarks: "No examination of a patient with pulmonary tuberculosis can be considered complete to-day without a roentgenological study of the intestines."

The first four articles in the *Wiener klinische Wochenschrift* for Jan. 8th deal with tuberculosis. In the first, Dr. M. Hayek, of Innsbruck, discusses the principles of actino-therapy in pulmonary tuberculosis and their relation to the problems of immunity. The value of this paper lies rather in its collection and discussion of current views than in any new matter it may contain. Following a paper by Dr. A. Engel on the statistics of pulmonary tuberculosis in the war—a dismal review—Dr. O. Orszagh gives an interesting account of the reaction of the subjects of tuberculosis to other infections. His figures show that the more advanced the pulmonary tuberculosis, the less violent is the patient's reaction to intercurrent affections, such as tonsillitis, and to vaccination. The last of these papers on tuberculosis is by Dr. W. v. Schulz, who discusses the examination of tuberculous sputum by the zinc precipitation method.

HOUSING NOTES.

The Economic Rent.

IN an article contributed to the current *Journal of the Royal Sanitary Institute* Mr. J. F. Smillie makes a useful contribution to the discussion of the economic factor in the replacement of slum dwellings. The new houses to be erected under the ægis of the Ministry of Health must conform to a rather high standard of amenity. The criticism constantly heard is that the present dwellers in slumdom will not be able to pay more than a small fraction of the rent of these new houses. Mr. Smillie points out that there are many far less attractive houses at present occupied by members of the artisan class, who are earning good wages. He argues that the new houses will easily be filled from this source, and that the dreary rows of Victorian architecture so deserted will provide an outlet from the slums. The process will resemble that which occurs in a colony of hermit crabs when an unusually large and desirable shell is washed among them by the tide. It is a compromise between the ideal and the practical, which certainly commends itself, and which should work out quite easily by the ordinary law of demand and supply.

The London Building Act.

The limit of height in London buildings was discussed at a meeting of the Royal Institute of British Architects on March 29th. Mr. Delissa Joseph read a paper in which he proposed a modification of the Building Act so as to allow of the erection of buildings up to 200 ft. in height opposite parks, public gardens, open spaces, and the riverside, and buildings equal in height to the width of a street when that width exceeded 80 ft. The proposal was made more attractive by suggesting that various improvements in town-planning might be carried out as a result of the increased value of present sites. The argument, however, is not convincing, even could we be sure that the increased value would come to the public purse. For every high building has more than one aspect, and it is only when its long shadow falls upon unoccupied ground throughout the whole day that the "sky-scraper" can be considered innocuous. There are, perhaps, a few sites on the southern bank of the river and on the south aspect of the larger parks, where such buildings might be erected with advantage to secure for city homes every available glimpse of sunshine, but any alteration in the existing Act must be carefully safeguarded. Under no circumstances must we permit in this country buildings such as have been described by Professor James Ford[1] as "a structure five or six stories high, or perhaps higher, built largely of wood, but with brick exterior, three or four rooms deep, sharing party walls with similar buildings to the right and left, sharing with its neighbours a narrow court or shaft, at the sides and at the rear an ugly yard." Hygiene must be secured, fool-proof lifts installed, and adequate security provided against the danger of fire.

URBAN VITAL STATISTICS.

(Week ended April 3rd, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18,000,000 persons, the annual rate of mortality, which had steadily increased from 15·6 to 18·7 in the six preceding weeks, fell to 16·7 per 1000. In London, with a population of nearly 4½ million persons, the annual death-rate was 16·3, or 3·0 per 1000 below that recorded in the previous week, while among the remaining towns the rates ranged from 5·7 in Carlisle, 6·3 in Oxford, and 7·8 in Wimbledon, to 27·7 in Blackburn, 29·8 in Wigan, and 43·4 in Dudley. The principal epidemic diseases caused 456 deaths, which corresponded to an annual rate of 1·3 per 1000, and comprised 180 from measles, 123 from whooping-cough, 72 from diphtheria, 63 from infantile diarrhœa, 11 from scarlet fever, 5 from enteric fever, and 2 from small-pox. Measles caused a death-rate of 2·6 in Lincoln, 3·6 in Wigan and in Newport (Mon.), and 5·0 in Barnsley. The 2 deaths from small-pox belonged to Liverpool. The deaths from influenza, which had steadily increased from 66 to 392 in the nine preceding weeks, fell to 379, and included 124 in London, 30 in Birmingham, 21 in West Ham, and 9 each in Manchester and Blackburn. There were 2023 cases of scarlet fever, 1983 of diphtheria, and 20 of small-pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 2101, 2043, and 14 respectively at the end of the previous week. The causes of 29 deaths in the 96 towns were uncertified, of which 6 were registered in Birmingham, and 3 each in Liverpool, St. Helens, and Manchester.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2¼ million persons, the annual rate of mortality, which had increased from 14·2 to 18·0 in the six preceding weeks, fell to 17·2 per 1000. The 376 deaths in Glasgow corresponded to an annual rate of 17·6 per 1000, and included 22 from measles, 15 from influenza, 3 each from scarlet fever, whooping-cough, and diphtheria, 2 each from small-pox and infantile diarrhœa, and 1 from enteric fever. The 117 deaths in Edinburgh were equal to a rate of 17·9 per 1000, and included 3 from influenza, and 1 each from measles, scarlet fever, whooping-cough, diphtheria, and infantile diarrhœa.

Irish Towns.—The 185 deaths in Dublin corresponded to an annual rate of 23·2, or 0·7 per 1000 below that recorded in the previous week, and included 10 from whooping-cough, 3 each from measles and influenza, 2 from infantile diarrhœa, and 1 each from scarlet fever and diphtheria. The 248 deaths in Belfast were equal to a rate of 31·3 per 1000, and included 33 from influenza, 5 from whooping-cough, 4 from infantile diarrhœa, and 2 each from measles and scarlet fever.

(Week ended April 10th, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality, which had been 17·9, 18·7 and 16·7 in the three preceding weeks, fell again to 16·6 per 1000. In London, with a population of nearly 4½ million persons, the annual death-rate was 17·6, or 1·3 per 1000 above that recorded in the previous week, while among the remaining towns the rates ranged from 6·3 in Cambridge, 7·8 in Wimbledon, and 7·9 in Smethwick, to 23·6 in Walsall and Halifax, 26·1 in Dudley, and 32·8 in Wigan. The principal epidemic diseases caused 440 deaths, which corresponded to an annual rate of 1·3 per 1000, and comprised 182 from measles, 101 from whooping-cough, 66 from diphtheria, 64 from infantile diarrhœa, 21 from scarlet fever, and 6 from enteric fever. Measles caused a death-rate of 3·0 in Wigan, 3·4 in Lincoln, and 3·6 in Newport (Mon.); whooping-cough of 1·2 in Southampton and 2·4 in Darlington; and diphtheria of 2·0 in Bootle and Aberdare. The deaths from influenza, which had been 312, 392, and 379 in the three preceding weeks, declined to 332, and included 105 in London, 30 in Birmingham, 13 in West Ham and in Manchester, and 10 in Plymouth. There were 2011 cases of scarlet fever, 1995 of diphtheria, and 26 of small-pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 2023, 1983, and 20 at the end of the previous week. The causes of 30 of the 5662 deaths in the 96 towns were uncertified, of which 6 were registered in Birmingham, 3 in Southend-on-Sea, and 2 each in Liverpool and Warrington.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2¼ million persons, the annual rate of mortality, which had been 17·8, 18·0, and 17·2 in the three preceding weeks, slightly rose to 17·3 per 1000. The 380 deaths in Glasgow corresponded to an annual rate of 17·8 per 1000, and included 21 from influenza, 17 from measles, 5 each from whooping-cough, diphtheria, and infantile diarrhœa, and 1 from scarlet fever. The 103 deaths in Edinburgh were equal to a rate of 15·7 per 1000, and included 6 from influenza, 2 from infantile diarrhœa, and 1 from diphtheria.

Irish Towns.—The 213 deaths in Dublin corresponded to an annual rate of 26·8, or 3·6 per 1000 above that recorded in the previous week, and included 13 from whooping-cough, 7 from measles, 5 from influenza, 3 from infantile diarrhœa, and 1 from enteric fever. The 207 deaths in Belfast were equal to a rate of 26·1 per 1000, and included 20 from influenza, 2 each from scarlet fever and whooping-cough, and 1 each from measles, diphtheria, and infantile diarrhœa.

Colonel C. Pye Oliver, C.M.G., M.D., Assistant Director of Medical Services, Home Counties Division, been placed on the commission of the peace for the of Kent.

ABDOMINAL EMERGENCIES.

To the Editor of THE LANCET.

SIR,—Professor Charles F. M. Saint, at the conclusion of his article in THE LANCET of April 10th on Abdominal Emergencies in which Operative Interference is either Contra-indicated or Restricted, justly states that the *general*[1] conclusions to be drawn from the cases that he cites are not new, but are worthy of recapitulation. In so far as he emphasises that operation is contra-indicated in certain abdominal emergencies, and the importance of making a careful investigation of history and symptoms, and thus arriving, if possible, at an accurate diagnosis by which an unnecessary operation may be avoided, his remarks are worthy of close attention. When, however, we come to study the cases he mentions in particular, certain statements he makes cannot be allowed to pass unchallenged, as the treatment he adopted, though apparently justified by the results, was, in my opinion, in certain instances surgically unsound. Let us take Case 15, the leaking duodenal ulcer. In this case the diagnosis made was a ruptured duodenal ulcer with a small leak which, though affecting the general peritoneal cavity at first, was *apparently*[1] at the time of admission, 36 hours after onset, "shut off." Operation was vetoed because he had "obvious trouble" in the chest, emphysema, and bronchitis, and there was a trace of sugar in his urine. After a somewhat slow convalescence he was discharged from hospital "much improved." I am not aware whether there are any statistics available of the results of the non-operative treatment of ruptured gastric or duodenal ulcer, but most surgeons will probably agree that the percentage of recoveries is extremely small and that the unfortunate existence of a belief in its efficacy has led to some terrible disasters.

Moynihan writes: "The possibility of spontaneous recovery, though not denied, is yet so remote as to make it imperative to adopt operative treatment at the earliest possible moment. The risk of operation is definite, the hazard of delay is immeasurable." Although it be admitted that the perforation was subacute, yet the risk of subphrenic abscess or of a septic inflammation spreading through the diaphragm to the chest was by no means inconsiderable. This gambler's throw was indulged in because the urine contained a trace of sugar and the lungs were somewhat emphysematous.

I next come to a criticism of Case 4, a case of appendix abscess. On deep palpation a mass could be felt on the right side of the pelvis, and per rectum this same mass could be reached high up with the tip of the finger and readily demonstrated bimanually. An appendix abscess was diagnosed, but operation was vetoed because it was thought probable that the abscess would evacuate itself naturally into the rectum. If we follow the good old surgical maxim to evacuate pus immediately we surely cannot go far wrong. What guarantee have we that the collection of pus before it has obliged the surgeon by emptying itself into the rectum may not track up and involve the subphrenic space or even burst and involve the general peritoneal cavity. Here, again, surely "the risk of operation is definite; the hazard of delay is immeasurable."

Case 11.—Pneumococcal peritonitis. A girl, aged 9, had acute peritonitis, which from a consideration of the history was considered to be pneumococcal and operation again vetoed. The little patient lingered on for four days and then passed away. Now, although the prognosis of the diffuse type and pneumococcal peritonitis is bad, it is by no means hopeless. Annand and Bowen[2] give particulars of 46 cases of the diffuse variety, of which 18 underwent operation. "Of the 18 cases operated on 6, or 33·3 per cent., recovered, whereas all those not operated upon died." The statistics given by Rischbieth,[3] Carmichael,[4] and Cameron,[5] although all emphasising the seriousness of the prognosis, show that the latter is by no means hopeless. It is difficult to understand why operation was vetoed with its chances of success, whereas the only alternative for the little sufferer was death.

I am, Sir, yours faithfully,
A. G. T. FISHER, M.C., M.B., Ch.B.,
F.R.C.S. Eng.,

THE HIPPURIC ACID SYNTHESIS TEST.

To the Editor of THE LANCET.

SIR,—The kidney, like the liver, is an organ with multiple functions. Every one of these functions must be tested individually, and among them is the synthesis of hippuric acid, which is more especially the work of the renal parenchyma. Therefore it is logical to think that the study of hippuric acid elimination may give useful data as regards the functional condition of the kidney. We do not wish to substitute any new method for methods which have proved their value, but simply to add a test which furnishes an independent and complementary control.

Hippuric acid elimination is profoundly influenced by diet. The greater the intake of food the greater the output of hippuric acid. The hippuric acid output is remarkably constant in the same individual taking every day about the same diet, both as to quality and to quantity. In five consecutive days differences found were very slight. Therefore it is enough to make a single estimation, providing a diet not devoid of green vegetables has been taken.

The "normal" figure measuring hippuric acid elimination gives no information as to how the renal parenchyma is functioning. Healthy individuals will give results varying greatly according to diet. Hence it is necessary to base a test on conditions not dependent on the intaken food.

The normal amount of hippuric acid having been estimated, we give the patient a dose of 0·5 g. of benzoic acid and another of 0·5 g. of glycocoll. Even this dose of glycocoll may be dispensed with, as the organism is able to manufacture it when needed, but it has the advantage that it greatly diminishes the slight toxicity of benzoic acid. From the time of taking these doses the total amount of urine is collected during 24 hours. Normally the synthesis should be complete within that time, and analysis should show an excess over normal of about 0·74 g. for 24 hours. This is the theoretical amount, but usually the excess is between 0·68 and 0·70. Since the normal output for a healthy subject is about 0·40 g., the figures we should expect to find are somewhat as follows: 1·14 g.—that is, 0·40 g. the normal amount and 0·74 the amount synthesised from the benzoic acid and glycocoll we have given. When the figure is lower, say 0·50, 0·40, &c., it may be asserted that the hippuric function is abnormal, and that probably there is some renal parenchymatous disorder. If this be the case, the analysis must be repeated on the following day to see if the experimental synthesis shows protracted insufficiency. In serious cases there may be no synthesis whatever on the following day, and the "normal" output found before the dosing is returned to. Generally the complementary amount is found, and the total synthesis is complete in 48 instead of 24 hours.

This test is mostly useful if carried out several times at fixed periods; for instance, at weekly intervals. I have had the opportunity of following patients and of noting either progressive augmentation or diminution of hippuric acid output in connexion with treatment.

From the point of view of hydrology, I am certain this method of investigation merits attention. Professors Desgrez and Adler have shown that acids diminish the power of the kidney to produce hippuric acid On the other hand, I have noted that diuretic waters (sulph calc) favour such a production, exciting the renal parenchyma, sometimes to such an extent as to double the output I am, Sir, yours faithfully,

---

TREATMENT OF GUINEA WORM

To the Editor of THE LANCET

SIR,—Towards the close of his interesting note on the treatment of guinea worm, which appeared in your issue of April 10th, Dr J Graham Forbes states that he welcomes the appearance of Dr J W S Macfie s paper on the use of intravenous injections of tartar emetic (THE LANCET, March 20th), especially as "there has been no advance in our knowledge of an effective cure for guinea worm which will cut short the tedium and risk of slow extraction by winding in vogue for so many years "

It seems advisable, therefore, to record the fact that both Jeanselme[1] and Montpellier[2] have recently employed injections of arsenobenzol, apparently with considerable success I append the references, as they may be useful —I am, Sir, yours faithfully,

ANDREW BALFOUR
Wellcome Bureau of Scientific Research 25–27 Endsleigh gardens N W 1 April 12th 1920

THE ÆTIOLOGY OF EFFORT SYNDROME

To the Editor of THE LANCET

SIR,—The results of Dr Gordon Barlow s thorough investigations on the Ætiology of Effort Syndrome recorded in your issue of March 13th rightly emphasises the recognition of infection as a common cause of the condition His conclusions on the nervous origin of these cases however, do not seem to be warranted even by his own findings I think there is little or no justification for giving the nervous element so insignificant a place All we know is that there is in a good many of these cases a definite illness of some such kind as influenza, from which the effort syndrome itself or the physical inactivity which leads to it dates It is by no means proved that, in some cases at least, the nervous depression following such a condition, or the simple weakness of convalescence merely prolonged, is not the father to the inactivity which leads to the effort syndrome It seems to me that the evidence deduced by Dr Barlow goes to prove beyond a doubt that a nervous state and the effort syndrome are very much more often than not conditions associated as sequel and cause, and vice versa If there is any one thing as important as any other in Dr T Lewis s ' The Soldier s Heart and the Effort Syndrome ' it is the multiple ætiology assigned to effort syndrome , in fact, the use of the term seems to be justified only in so far as it implies a vague ætiology

With the introduction of new terms the tendency seems to prevail of limiting our attention to the condition of the organ which was responsible for the introduction of the new term From this weakness of ours I suppose arises the attempt to exclude the nervous factor in the causation of the effort syndrome The man in the street knows as well as the physician that the weakness following any illness is not a manifestation of damage done to the heart alone except perhaps in rheumatic fever In the case of influenza, which is so important an ætiological factor in the effort syndrome, the harm done to the body as a whole is most obvious, and its special effect on the nervous system is apparent as nervous depression Why in the face of all that the histories of these patients show —disturbed sleep terrible dreams worry, anxiety, and a host of other symptoms—an attempt is made to eliminate the nervous factor is not clear Perhaps it is partly because we explain them as "neuroses,' ill defined but none the less clinical entities From the examination of a large number of these cases I am convinced that the nervous element is a very important factor both in the production and the aggravation of this condition It seems to me that the cardiac manifestations are only more obvious, and the nervous still linger in the threshold of the "neurotic ' and the "neurasthenic state The latter are less obvious but no less important from the point of view of treatment We know that apart from deficient physical exercise, neglected convalescence from acute illnesses and excessive physical exercise other conditions may produce the effort syndrome at least transiently, from some hours to a day or two for example, traumatic neurasthenia (in which may be included "war neurasthenia), insomnia, the condition of the "morning after the night before We can demonstrate this ourselves if only we break rest for two or three nights consecutively and attempt anything like moderately hard work Just because we have begun to use a new term, the effort syndrome, when it essentially means symptoms of general weakness, why should we try to prove that in the *former* the symptoms cannot be of nervous origin, whilst in the latter it can Both from the point of view of treatment and of the diagnosis of the more serious conditions which can give rise to the effort syndrome it seems wiser to regard the condition as having a multiple ætiology Furthermore it can hardly be denied that every bad case of neurasthenia exhibits the effort syndrome, and, at least in these cases, neurasthenia remains the cause of the condition True enough these cases are no longer effort syndrome as some look at it for the nervous symptoms predominate

Even so eminent a cardiologist as Dr Lewis only entertains the unlikelihood of this condition having a "*purely* nervous origin It is very true all these cases cannot be said to be due to a "functional neurosis but that not a few are of nervous origin has yet to be disproved We cannot lay too much stress on a primary origin for a history of infection is positive not only in a large percentage of "effort syndrome cases but in all kinds of patients or even healthy men The fact that judicious exercises cure these cases does not disprove the nervous origin of some at least of them for no treatment can be better for anybody in the pre neurasthenic state It seems to me to be, on the whole better to look on these cases as of dual origin at least for if such a conception draws our attention to the simultaneous treatment of the nervous system, the rest of the body—and the mind—our patients will have the most thorough treatment

VACCINES AND THE DIPHTHERIA CARRIER

To the Editor of THE LANCET

SIR,—If I may presume to make comment on Professor J Eyre s most interesting letter in your issue of April 10th on the above subject I might say that in my original thesis, of which the paper appearing in THE LANCET of March 27th was a synopsis I reviewed the literature relating to the problem of the diphtheria carrier and quoted in full the passage from Bosanquet and Eyre, "Serums Vaccines and Toxins, pp 134 136 which included the sentences brought to notice by Professor Eyre My comment was that vaccine treatment was not unduly obtruded and, the recommendation that it should be "autogenous,' made its application unattractive and its general availment problematical I have had no experience of "autogenous diphtheria vaccine, but the question of the superiority of "polyvalent" diphtheria vaccine is still under consideration and only awaits time and experimental proof for its elucidation As however, the series of cases dealt with was treated with "monovalent vaccine I fear that ' confirmatory evidence for the efficacy or superiority of any other was hardly afforded Any claim made was for the realisation that with a large number of patients consistent results were obtained in a reasonable time and that, accordingly, the absolute necessity for "autogenous" vaccination appeared not to exist. To make autogenous vaccines for hundreds, if not thousands, of diphtheria carriers would entail such an expenditure of labour, time, and money as very effectually to put their general employment outwith the province of routine practice and practicable therapeutics. After all, the necessary facilities for the elaboration of complex media are not given to everyone who has to work with such cases, nor can the requisite technical skill on the part of the administrator often be presumed. On the other hand, "stock" vaccine might quite readily be produced centrally and distributed much in the same way as is practised with antidiphtheritic serum itself.

---

[1] Jeanselme E Bulletin de l Académie de Médecine (Paris) 1919 Feb 4th Year 83 3 Ser vol lxxxi p 156

[2] Montpellier J Bulletin de la Société de Pathologie Exotique 1919 Dec vol xii p 730

Unquestionably, availability coupled with ready and easy administration are the criteria by which any therapeutic measure must be judged. Only in so far as these are present will general favour be bestowed on it. It is scarcely necessary to suggest that if antidiphtheritic serum required to be autogenous, and if every physician who to-day considers its administration a simple routine practice were called upon to undertake its manufacture diphtheria would not claim for itself the finest results in the whole field of serum therapy. If the omission of "washing with several changes of normal saline" increases the liability to "uncomfortable local reactions" it has not manifested itself in over 200 injections of four separate vaccines extending over a period of years, but if experience proved the necessity, such (and other refinements of technique which may from time to time be devised) might well be practised without materially affecting the labour of preparation. This very circumstance might conceivably be used as an additional plea for the advisability of producing "bulk" vaccine, as by such manœuvre the undoubted liability to error through variability of media would be eliminated.

I am, Sir, yours faithfully,
J. L. BROWNLIE.
Glasgow Corporation Laboratory, April 10th, 1920.

CARDIAC ENLARGEMENT IN CHILDREN: THE X RAY DATA.

To the Editor of THE LANCET.

SIR,—I should be greatly obliged if any of the readers of THE LANCET, who may have had experience in X ray methods of detecting and estimating cardiac enlargement, could inform me if, in their experience, the X ray data which are laid down for estimating cardiac enlargement in adults hold good in children. This question more especially refers: (*a*) to the "Cardiac-Thoracic Diameter Ratio," in adults, 39 to 50 per cent. normal, and 53 per cent., or over, pathological; and (*b*) to the apical "Index of Depth," of 7–14 mm. normal, in the adult, and 20 mm. and above pathological.

In particular, I would like to obtain a table of the various "Indices of Depth" at different ages. For instance, if, in a child of 6 years, the index of depth is 6 mm. and the cardiac-thoracic diameter ratio is 46 per cent., could such a heart be considered enlarged? My view is that it would not.

I am, Sir, yours faithfully,
Royal Sussex County Hospital, C. FRED. BAILEY.
Brighton, April 10th, 1920.

BLIND MASSEURS.

To the Editor of THE LANCET.

SIR,—Probably those of us who do not agree with all that has been written in favour of the blind masseur have been restrained by our sympathy for the individual, but I feel that to allow one side of the question only to be stated is unfair both to the patients and to those doctors who have not specialised in this particular form of treatment. The following points require consideration:—

1. No blind person can satisfactorily control the free-standing exercises used in the treatment of the common deformities. Even the resistive exercises and pressures can only be applied by the continuous handling of the patient from head to foot. Such handling is obviously undesirable, and to my mind positively detrimental to the treatment. The following exercises may be mentioned as a few examples beyond the scope of the blind:—Klapp's creeping exercises, Fraenkel's exercises, hanging in head suspension apparatus, side-lying over boom, balance walking, correcting in belt.

2. Only the sighted can control the balance and coördination exercises used for chorea, tabes, disseminated sclerosis, &c. In these cases, handling of the patient destroys the desired effect.

3. In the treatment of cardiac cases the most careful observation is absolutely essential. No blind gymnast can possibly detect the slight changes in colour and general expression which are the early warnings of strain.

4. The coöperation of the patient is especially necessary when the gymnast is blind. It is common knowledge that certain patients, malingerers and not infrequently school children, rather than being helpful, are positively obstructive. It is the simplest thing in the world for a troublesome patient to completely deceive the blind and so nullify the treatment.

5. The general practitioner frequently states that the private patient expresses reluctance to being treated by anyone not physically fit. The private patient is, of course, free to make his choice, but the exercise of this somewhat natural instinct is denied to the hospital patient. In this connexion I should like to point out that the sighted workers in a large department invariably find that they have extra labour thrown upon them where a number of workers are blind, as it is universally admitted that special cases have to be picked out for treatment by the latter.

6. The capabilities of the blind in the field of electrotherapy still remain to be discussed.

For the above reasons I suggest that it is unfair to the blind themselves to insist that their work is absolutely equal to that of the sighted; and to demand from them an equal standard is to place them in a false position, which is not to their ultimate advantage. My excuse for giving these views is that I have come across a number of blind masseurs who feel very strongly their own limitations, and who state that more is being demanded of them than they can possibly accomplish.

I am, Sir, yours faithfully,
E. M. MAGILL, O.B.E., M.B., B.S.,
Late M.O. in charge of X Ray, Electro-therapeutic and Massage Departments, Military Hospital, Endell-street, W.C.
Bedford-place, W.C., April 11th, 1920.

AFTER-EFFECTS OF MALARIA.

To the Editor of THE LANCET.

SIR,—I should like to refer shortly to the letter in your issue of March 27th by Dr. A. Hurrell Style, whose observations suggest a causal connexion between malaria and arterio-sclerosis. That the malarial poison may be a producer of arterio-sclerosis, just as in the case of rheumatism, gout, scarlet or enteric fever, is quite possible, and that arterio-sclerosis is to found in a certain proportion of cases of malaria is certain. There is, however, in my mind a possible fallacy which would require to be eliminated in order that incidental concurrence may not confuse the issue—namely, that we have in very few cases indeed any evidence of the condition of the arteries prior to the incidence of malaria.

Those of us who had opportunities of examining many hundreds of young adults during the period of recruiting had occasion frequently to draw attention to the remarkable degree of arterio-sclerosis to be found occasionally in comparatively young men otherwise apparently healthy. It would certainly be of value if some observer could elucidate this point.

I am, Sir, yours faithfully,
JAMES R. WHITWELL, M.B.
St. Audry's Hospital, Melton, Suffolk, April 12th, 1920.

Sir James Barr, C.B.E., LL.D., has been appointed a Knight of Grace of the Order of the Hospital of St. John of Jerusalem in England.

Medical News.

Royal College of Surgeons of England —A quarterly meeting of the Council was held on April 8th, Sir George H Makins, the President, being in the chair —The secretary reported the death on March 23rd, of Mr George Arthur Wright, past member of the Council The following resolution was passed —

> The Council hereby express their deep regret at the death of Mr George Arthur Wright whom they highly esteemed as an able surgeon keenly interested in the advancement of surgical skill and knowledge and they desire to convey to Mrs Wright their sincere sympathy and condolence in the loss which she has sustained *The Council do also record their appreciation of Mr Wright's services to the College as a member of the Council and also of his work in the museum at an earlier period of his professional career*

—A vote of thanks was given to Mr C Kirkman Finley for presenting through Mr J G Turner, F R C S, the skulls of 20 Burmese and 4 Chinese who were executed in gaols in *Burmah* —A vote of thanks was given to Sir Rickman Godlee for presenting the original drawings which he had made for his "Atlas of Human Anatomy," 1880, and the calvaria of the patient he trephined in 1884 for the removal of a cortical tumour, the first operation of its kind —In accordance with the recommendation of the Jacksonian *Committee*, it was resolved that the subject for the Jacksonian prize for the year 1921 should be "The Pathology, Diagnosis, and Treatment of Tuberculous Disease of the Spinal Column with its Complications" —The following Members of 20 years' standing were elected to the Fellowship Henry Alexis Thomson C M G, *Professor of Surgery, University of Edinburgh*, and Wilfred Thomason Grenfell, C M G, Superintendent of Labrador Medical Mission and of Royal National Mission to Deep Sea Fishermen

Chadwick Public Lectures —On May 4th, 7th, and 11th, at 5 P M, in the Pathological Lecture Hall of the *New Medical Schools* at *Cambridge*, Dr F G Crookshank will deliver three lectures on Man and Disease On May 17th, at 7 30 P M, in the Town Hall, St Helens, Lancashire Captain R Reiss, chairman of the executive committee of the Garden Cities and Town Planning Association, will deliver a lecture on Housing and Health, and at 7 P M on May 12th and 13th, in the Town Hall, Colchester, Mr A J Martin, M Inst C E will discuss the question of sewage and its disposal Admission to these lectures is free

University of Manchester Appeal —The monotony of the appeals reaching us from educational and benevolent institutions throughout the country is pleasantly varied by the novel prospectus entitled "Lancashire Development Unlimited" just issued by the University of Manchester For a month Manchester and the towns in its sphere of influence are to ring with the cry, "Invest in your University" In order to raise the £500,000 of new capital needed to maintain and develop the University an altogether original procedure is being adopted Designed to appeal principally to prosperous business firms, many of which have already become subscribers, the requirements of the University are set out in the terminology of a company in which the public are invited to take shares, non redeemable, and bearing no pecuniary interest, and thus provide new capital amounting to £500 000 It *offers*, on behalf of the University, 425 000 cumulative ordinary bonds of £1 each, and 1 500,000 cumulative participating people's bonds of 1s each The terms are "On application as much as possible, on allotment, may be spread over three years at the option of subscriber" All citizens are invited to equip, endow, and enrich the work of the University, which touches life in all its phases, and are urged not to miss this "rare opportunity for a richly paying investment in the unlimited wealth of the human mind" Dealing with the profits and advantages to the investor, the prospectus refers to Lancashire's great cotton industry and to the health of her people as her first interest The prospectus states that the faculties of medicine, surgery, and public health are constantly at work to ensure that hospitals are staffed with men of the highest competence, so that the child of the Lancashire weaver can get the same skilled treatment as the child of the millionaire The chief faculties touch the lives of all the people at every point Of the sum required £171,000 will *be absorbed by various developments* and extensions already decided upon The war services of the University are on record, and with the return of peace it is hoped that "the new capital now issued for public subscription will enable the University to perform its appointed task of organising and leading our great county in the works of *peace*" The *prospectus concludes* "You are earnestly invited to have a personal share in the development of Lancashire" Subscriptions may be sent to the organising secretary, Mr G A Marriott 9, Albert square, Manchester

A **reunion** dinner of all the ladies and gentlemen who have served the 1st London (City of London) General Hospital (including its sections and auxiliaries) will be held on Wednesday, May 12th, at 7 30 P M, in the Wharncliffe Rooms, Hotel Great Central, Marylebone road, London, N W, to be followed by an informal dance Evening or mess dress will be worn Tickets price 1 guinea, can be obtained before May 7th from the honorary secretary, Lieutenant Colonel W McAdam Eccles, 124, Harley street, W 1

Edward Hain Memorial Cottage Hospital, St Ives —The shareholders of Edward Hain Steamship Company and Lady Hain have given and endowed a cottage hospital at St Ives, Cornwall, as a memorial to the late Captain Edward Hain, killed at Gallipoli A large house has been purchased and fitted up as a cottage hospital and convalescent home to accommodate ten patients £10 000 have been invested as an endowment fund, which will give an income of £500 per annum The institution was formally opened on April 8th by Lady Hain, in the presence of a large gathering

Winsley Sanatorium, Bath —The annual report of this institution for 1919 states that during the year 457 patients were admitted, compared with 500 in 1918 The average stay of each was 86 days against 77 in the preceding *year The results of the treatment continued to be very* satisfactory The income amounted to £10,815, and the expenditure was £10,942 The committee anticipates that the sanatorium will be able to accommodate a greater number of patients in the future

Sherborne (Dorset) Hospital —The annual meeting of the friends of the Yeatman Hospital was recently held The financial statement showed the annual income to be about £1500 per annum, whereas the expenditure was £4000, consequently a special subcommittee had reported that unless new sources of revenue were devised *the hospital must be totally or partially closed* It was *decided that, with the exception of* old age pensioners, all in patients *should* be charged *from 7s 6d* weekly and out *patients should pay 1s for each visit*

The Anglo American University Library for Central Europe —*A preliminary statement has been issued* by Professor Gilbert Murray, Mr Arnold Rowntree, and the Rev William Temple, acting as trustees designed to call earnest attention to a scheme for establishing in Central Europe under British and American auspices, libraries of recent English and American works, on gift or loan, which are indispensable to university teachers The origin of the scheme may be *traced to the relief work in Central Europe* conducted by the English and American Society of Friends, by whom the privations of university teachers have been brought to attention Owing to the unfavourable rate of exchange and the high cost of living the prices of recent English and American works on philosophy, science, and belles *lettres* have *made it impossible for* the universities of Central Europe to keep in touch with English and American thought (For example, 10s books cost an equivalent of more than £9 in Germany and more than £30 in Austria) As a consequence the scholars in these countries find themselves cut off from access to books printed in English since 1914 The object in view *in forming the Anglo American* library is two fold, the promoters aim at relieving the hunger of mind, while promoting that reconciliation of spirit which can only follow on the free interchange of ideas The libraries, which will be organised on a broad non political, non sectarian basis, so as to enlist the widest possible cooperation, will supply on loan books needed by the faculties of the different universities in *Central Europe* They will be under the charge of British and American representatives, and committees of the foreign universities will be asked to superintend the local administration Lord Bryce, Lord Robert Cecil, and other leading public men have promised their coöperation in carrying it out In *addition to the trustees* mentioned above a consultative committee of British and American university men will be formed as soon as possible With such assistance little difficulty need be anticipated in securing the necessary financial support Professor Everett Skillings, of Middlebury College Vermont, U S A, is leaving shortly for the Continent to confer with the university authorities *there* The preliminary statement closes thus —

> By taking the initiative in extending the hand of fellowship to colleagues in former enemy countries British and American scholars are seizing a timely opportunity of helping to heal the wounds of the war and of exemplifying in a practical and convincing way the true international mind

Mr B M. Headicar, librarian of the London School of Economics (University of London), Clare Market, London, W C 2, is acting as Secretary of the Library, and all communications may be sent to him at that address

ROYAL NATIONAL HOSPITAL FOR CONSUMPTION, VENTNOR.—The fifty-first annual general meeting of the governors of this hospital will be held at 33, Portland-place, London, W., on Monday, April 26th, at 4 P.M., the Right Hon. J. E. B. Seely in the chair.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.—A course of post-graduate lectures on syphilis is being given by various members of the staff of King's College Hospital during the present year. On Friday, April 23rd, at 9.15 P.M., Sir StClair Thomson will speak on Syphilis of the Throat and Larynx.

AT the monthly meeting of Fellows of the Royal Faculty of Physicians and Surgeons of Glasgow, held on April 12th, Dr. James Alexander Adams was elected representative to the General Medical Council for the period of five years. Dr. Adams succeeds Dr. D. N. Knox, who has resigned on the ground of ill-health after holding office for 12 years.

THE annual medical meeting of the Society for the Propagation of the Gospel in Foreign Parts will be held at 8 P.M. on April 21st, in the Central Hall, Westminster, Dr. S. Russell Wells in the chair, when Rev. F. G. Hodder-Williams, M.B., B.S., Fellow of Allahabad University, will speak.

ROYAL MICROSCOPICAL SOCIETY.—This society, in conjunction with the Optical Society and the Faraday Society, is holding a discussion on the Mechanical Design and Optics of the Microscope at 20, Hanover-square, London, W., on Wednesday, April 21st, from 7 to 10 P.M. Professor John Eyre will preside, and Mr. J. E. Barnard, Dr. W. Rosenhain, and Professor A. E. Conrady, among others, will take part.

ROYAL ARMY TEMPERANCE ASSOCIATION.—The twenty-fifth annual meeting and conference of this association will take place at the Caxton Hall, Westminster, on May 4th. At the annual conference of regimental delegates and male friends, at 11 A.M., the chair will be taken by Lord Horne, and the speakers on "Alcohol in our life to-day" will include Dr. G. Basil Price and Mr. Arthur Evans.

INFLUENZA AND ENCEPHALITIS LETHARGICA IN SWITZERLAND.—In December, 1919, only 511 cases of influenza were medically notified in Switzerland (population, 4.000,000). In January, 1920, already 13,162, in February 83,008. In February, 1920, 440 cases of encephalitis lethargica occurred. The epidemic of influenza has almost ceased, that of lethargic encephalitis has greatly decreased. The number of deaths is not yet officially notified.

KING'S COLLEGE, LONDON, OLD STUDENTS' ASSOCIATION.—At a general meeting of old students held recently at King's College, Strand, it was decided to form an association for the purpose of promoting social intercourse and of keeping the members in touch with their old college. It is hoped to include students from all faculties and the subscription of 10*s*. 6*d*. per annum will include the *King's College Review*. Further particulars and forms of application for membership may be obtained from the honorary secretary, Miss M. A. W. Fairlie, 3, St. Julian's Farm-road, W. Norwood, S.E. 27.

LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.—The annual general meeting of this society was held at the offices, 32, Craven-street, Strand, London, on March 17th, when the annual report of the council, which showed both an increase of membership and a strengthened financial position, was presented. The total membership of the society on Dec. 31st, 1919, amounted to 5688, and during the year 65 members died, 121 resigned, and 689 were elected. The funds of the society increased from a surplus balance of £23,955 4*s*. 4*d*. in December, 1918, as compared with a balance of £25,825 11*s*. 1*d*. on the corresponding date of 1919. The council refer to the loss sustained by the deaths of a distinguished vice-president in Sir William Osler and a valued member of council in Dr. T. W. Atkinson.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST: PAYMENTS BY PATIENTS.—At the annual court of governors of this hospital the chairman stated that although the financial position at the end of 1919 might be considered satisfactory, the outlook for the present year was by no means free from anxiety, particularly in view of the urgent need of structural improvements. The annual expenditure had risen from £14,000 in 1914 to £28,000 last year, and it was feared that in the coming year it would be still further increased. It was necessary to raise a substantial sum of money, and the committee had considered the desirability of trying to get some contributions from the patients. A resolution was passed giving the committee power to make such a charge as it might consider to be reasonable.

QUEEN VICTORIA CONVALESCENT HOME, DURDHAM DOWNS.—The annual report of this institution just issued states that from July, 1916, to July, 1919, the home was occupied by military patients, 1594 being admitted for an average stay of one month. The home has recently been thoroughly renovated at a cost of £2679, and will be ready for the reception of patients on May 1st. The committee appeals for £5000 to extend the building, and to provide additional accommodation for ten men and ten women. £1700 have been received, and it is hoped that the balance will shortly be subscribed.

THE CHEMISTS' EXHIBITION.—A visit to this exhibition, which was opened on April 12th at the Northampton Institute, Clerkenwell, left the impression that pharmacists and druggists and others related to the calling were serving well in the interests of the medical profession. There were some excellent specimens of fine drugs, chiefly synthetics and alkaloids, shown, but a feature of this year's collection was a profusion of perfume exhibits. It would appear that this industry is growing rapidly in this country, replacing, probably, foreign productions. The two halls were well stocked with interesting products, and the stalls were attractively arranged. That these occasions continue to receive the support of exhibitor and visitor alike is obvious from the fact that this is the twenty-first of the series, though gaps were caused, of course, during the years of the war. The organisers are the proprietors of the *British and Colonial Pharmacist* newspaper. The exhibition closed on April 16th.

IN the newspaper reports of the recent outbreak of fire at St. Dunstan's College for Blinded Soldiers, Regent's Park, reference has been made to the excellent manner in which the blinded men and their nurses escaped from the burning building. The St. Dunstan's authorities have given the question of prompt escape from their various buildings in case of fire their constant and earnest attention, and have spent considerable sums of money in providing suitable emergency exits, external staircases, and other fire escapes, for each of the homes in which they are interested. These arrangements have been efficiently carried out by and in consultation with Messrs. Merryweather and Sons, Greenwich and London, who have also instituted a system of periodical inspection of the fire extinguishing and escape arrangements. The blinded soldiers and the nurses are regularly drilled, and the wisdom of these measures was demonstrated at the recent fire.

Parliamentary Intelligence.

HOUSE OF COMMONS.

MONDAY, APRIL 12TH.

St. Luke's Hospital, Bradford.

Mr. MYERS asked the Minister of Health if his attention had been called to the agreement made between the Bradford corporation and the Bradford board of guardians in respect of the utilising of St. Luke's Hospital as a municipal general hospital; whether he was aware that this arrangement would enable the Bradford corporation to treat the sick, irrespective of their economic circumstances, and avoid the stigma attached to Poor-law treatment; whether the Ministry of Health was prepared to encourage and assist the project; and, if so, would he inquire into the circumstances prevailing in his department which were stated to be causing delay in putting the scheme into operation.—Dr. ADDISON replied: The scheme to which the honourable Member refers was approved by me last month.

Mr. LYLE: Will the consent of the Ministry of Health be extended to other local authorities putting forward similar proposals, and does this step agree with the policy enunciated in February, 1919, in this House and elsewhere? Is the right honourable gentleman now in a position to make a statement on the policy of the department in respect to voluntary hospitals?—The SPEAKER: The honourable Member had better give notice of that question.

Nurses and 1914 Star.

Lieutenant-Colonel FREMANTLE asked the Secretary for War whether nurses sent to Malta on active service in 1915 were ineligible for the 1915 medal, while nurses serving in Alexandria under similar conditions were entitled to it; and whether there were any reasons, other than those of administrative convenience, why equal services in Malta should not be equally recognised.—Mr. CHURCHILL replied: Service on the establishment of a unit in a theatre of war is essential to qualify for the award of the 1914-15 Star. Malta was not a theatre of war and nurses who served there in 1915 are consequently not eligible for the Star.

Obituary.

ALBERT JOHN CHALMERS M D VICT & LIVERP, F R C S ENG D P H

NEWS reached London last week that Dr A J Chalmers died of acute infective jaundice in the General Hospital at Calcutta on April 5th He was born at Manchester in 1870, son of Rev James Chalmers, M A, and was educated at Manchester Grammar School and University College, Liverpool Qualifying in 1890, he held the Holt Fellowship of University College, Liverpool, before entering the West African Medical Service, acquiring in his four years on the Gold Coast that zeal for tropical medicine which lasted throughout his life In 1901 he accepted a call to Ceylon, and for the next ten years was registrar at the Colombo Medical College, where he lectured on pathology and animal parasitology and had the satisfaction of witnessing the development of the College into one of the principal teaching institutions in the East After a period of service with the Pellagra Field Commission he became, in 1913, director of the Wellcome Tropical Research Laboratories at Khartoum, a position from which he was taking a well earned study holiday at the time of his early death Chalmers was an enthusiast and a never tiring worker, whose literary output was very large, as witness the 2500 pages of the third edition of the 'Manual of Tropical Medicine,' in every part of which he collaborated with Castellani His work on madura foot and on tropical skin diseases in general is of permanent value, and tropical medicine has lost in him one of its most faithful servants A loyal friend and a generous colleague, Dr Chalmers was also a popular practitioner when the opportunity was open to him in Colombo In 1911 he received the Coronation Medal, and he also held a medal and clasp for the Ashanti Expedition of 1900, but his chief honours lie in the work which he did and the work which he inspired others to do Dr Chalmers leaves a widow, daughter of the late Edwin Cannington, J P but no children

HECTOR TREUB,

PROFESSOR OF GYNÆCOLOGY IN THE UNIVERSITY OF AMSTERDAM

Professor Treub s death last week in his sixty fourth year, removes one of the best known continental gynæcologists Three sons were born to Burgomaster Treub, of Voorschoten, near Leyden The eldest Melchior, came to be professor of botany, and founded the important Institute of Tropical Botany on the island of Java, the youngest, Willem, also at one time professor in Amsterdam became an authority on sociology and a leading member of the Lower Chamber, while Hector, at first in Leyden, transferred later to a professorial chair at Amsterdam, established his reputation as the leading authority on diseases of women in Holland, celebrating his 25 years jubilee as professor in 1912 Treub was a prolific writer in Dutch medical journals on his special subject, his first published work in the domain of operative gynæcology dating from 1885, later extending over extra uterine pregnancy, fibroma, sterility, retroflexion, and enteroptosis, as well as such general medical topics as the civil rights of practitioners, reformed clothing for women, and the co education of medical students In two little books on medico political subjects he collaborated with A Tak and C Winkler He was for 20 years co editor of the *Geneeskundige Bladen*, published in Haarlem

ALEXANDER HODGKINSON, M D MANITOBA M B, CH B VICT, M SC VICT

SURGEON TO THE WARRINGTON INFIRMARY

Dr A Hodgkinson, who died at his home at Ivy Lodge, Warrington, on April 6th, after four days illness with pneumonia, was in his forty third year In 1898 he obtained a B Sc degree in the Victoria University with first class honours in zoology, proceeding to the M Sc in 1901 He gained the Dauntesey Entrance Medical Scholarship and the Dalton Natural History Scholarship After taking his M B, Ch B with honours he spent some time in resident hospital appointments at Warrington Infirmary and elsewhere, and then settled in practice in Warrington, where he had a large connexion At various times he held visiting posts at the Warrington Union Infirmary, the Warrington General Infirmary, and the Whitecross Military Hospital He was at all times deeply interested in natural science and for a time lectured at the Warrington Technical School on this subject It was a surprise to many that he did not adopt a purely scientific career, for which in his student days he appeared destined In 1914 he proceeded to the ad eundem M D degree of the University of Manitoba

THE LATE DR T W. LAMBERT —Thomas Wilson Lambert, who died suddenly at Mentone on March 31st in his fifty eighth year, was a native of Yorkshire, and was educated at Cheltenham and at Pembroke College, Cambridge After qualifying with the M R C S Eng, L R C P Lond in 1889, he held house appointments at St Thomas's Hospital, where he had received his medical training and in the following year graduated M B, Ch B at Cambridge University Subsequently he was appointed medical officer to the Canadian Pacific Railway, and to the Royal Inland Hospital, Kamloops For many years he held a prominent position in Columbia, and in 1897 was elected vice president of the College of Physicians and Surgeons of British Columbia holding the office of president 1898 99 On his return to Europe he spent part of his time in England and part in Norway, and numbered among his friends in the latter country Henrik Ibsen During the war he acted as director of the Scandinavian section of the Foreign Press Department at the War Office Dr Lambert was an ardent sportsman, and was the author of a book on "Fishing in British Columbia" At Cambridge he was a famous oar, rowing for the University against Oxford on several occasions

The Services.

R A M C PAY IN INDIA

THE new scale of grade pay for officers of the Royal Army Medical Corps in India has effect from July 1st 1919 The scale is as follows —

	Rs per month
Lieutenants	550
Captain on promotion	650
Captain after 5 years total service	700
Captain after 7 years total service	750
Captain after 10 years total service	850
Major on promotion	950
Major after 3 years as such	1050
Lieutenant Colonel	1350
Lieutenant Colonel after 3 years as such	1500

Charge allowances are admissible in addition Army of occupation bonus is not paid with these rates but where the old rates with the bonus are more favourable they may be retained until the general abolition of the bonus or until promotion whichever is earlier These rates of pay are provisional and will be subject to revision when permanent rates of pay for the medical services in India are fixed The new rates of pay in the Indian Medical Service were published in THE LANCET of May 3rd 1919, p 764 and may be referred to for purposes of comparison

Royal Eye Hospital, St. George's Circus, S.E.—Sen. H.S. £100. Also Clin. Assts.

Salford Royal Hospital.—H.S. £150.

Sheffield Royal Infirmary.—Two H.S's, one Ear, Nose, and Throat H.S. £150.

Southend Victoria Hospital, Southend-on-Sea.—H.S. £200

South London Hospital for Women, South Side, Clapham Common, S.W.—Female H.P. £100.

Stamford, Rutland, and General Infirmary, Stamford.—H.S. £200.

Stoke-on-Trent, North Staffordshire Infirmary.—H.S. £200.

Straits Settlements and Federated Malay States.—Thirty-three M.O.'s. $440 per month.

Swansea General and Eye Hospital.—Jun. H.S. £200.

Trowbridge, Wilts County Council.—Third Sch. Dent. £400.

Wakefield, Clayton Hospital.—Sen. and Jun. Res. H.S. £250 and £200.

Wallasey, Victoria Central Hospital and Wallasey Dispensary.—H.S. £250.

Wells Asylum, Somerset.—Sen. Asst. M.O., £400.

West End Hospital for Nervous Diseases, 73, Welbeck-street, W.—Hon. Med. Registrar.

West London Hospital, Hammersmith, W.—Asst. Anæsth.

West Riding County Council.—Sch. Med. Inspec. £500.

Woolwich Tuberculosis Dispensary, Maxey-road, Plumstead, S.E.—Asst. Tuberc. O. £500.

Worcester County and City Mental Hospital, Powick.—Deputy Supt. £450. Also Jun. Asst. M.O. £300.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshops Acts at Hebden Bridge, Liskeard, Markfield, Singleton, Stonehaven, Stornoway, and at Wolverhampton.

The Home Secretary gives notice of a vacancy for a Second Medical Referee under the Workmen's Compensation Act, 1906, for the Marylebone and West London (Brompton) County Courts. Applications should reach the Private Secretary, Home Office, not later than May 5th, 1920.

Births, Marriages, and Deaths.

BIRTHS.

ADAMS.—On April 6th, at a Nursing Home in Chiswick, the wife of Dr. J. Wroth Adams, of a son.

METHVEN.—On April 8th, at King's-avenue, Clapham Park, S.W., the wife of J. C. W. Methven, M.R.C.S., L.R.C.P., of a son.

TERRY.—On April 1st, at Barton-street, Gloucester, the wife of H. Cairns Terry, M.B., of a son.

WARNER.—On April 1st, at Rydal, Woodford Green, Essex, the wife of Dr. H. P. Warner, of a son.

WATERS.—On April 8th, at Cranmore, Lymington, the wife of Dr. J. P. F. Waters, Maudsley Neurological Hospital, London, of a son.

MARRIAGES.

ATTLEE—MACONOCHIE.—At St. Paul's Church, York Place, Edinburgh, on Thursday, April 8th, by the Very Rev. the Dean of Edinburgh, Wilfrid Attlee, M.D., of Eton, youngest son of the late John Attlee, of Dorking, to Emily Bridget, younger daughter of C. C. Maconochie, K.C., C.B.E., of Avontoun, Linlithgow.

LETHEM—LAWRENCE.—On April 3rd, at the Parish Church, Adlington, Lancashire, William Ashley Lethem, M.C., M.B., D.P.H., to Barbara, youngest daughter of the late James Lawrence, J.P., and Mrs. Lawrence, of Kilhey Court, Worthington, Wigan.

VOSPER—RUDKIN.—On April 7th, at St. John's Church, Wembley, Middlesex, Cecil Vosper, M.R.C.S., L.R.C.P., to Catherine Alwine, younger daughter of Frank Rudkin, of Sudbury, Harrow.

DEATHS.

BIGG.—At Chagford, Devon, on March 29th, Edward Bigg, M.A., B.C. Cantab., and M.R.C.S., L.R.C.P., aged 45.

CHALMERS—On April 5th, at Calcutta, Albert John Chalmers, M.D., F.R.C.S., Director of Wellcome Laboratories, Khartoum.

LAMBERT.—On March 31st, at Mentone, France, Thomas Wilson Lambert, M.D. Cantab. L.R.C.S., L.R.C.P., son of the late Joseph Lambert, Cottingham.

NASH—On April 8th, Walter Llewellyn Nash, M.R.C.S., F.S.A., aged 78 years.

TICHBORNE—On April 6th, at his residence, Madeley-road, Ealing, of pneumonia following influenza, John Tichborne, M.D. Dub., late S.M.O., Northern Nigeria, and late Captain, R.A.M.C.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MEDICAL PROBLEMS OF LIFE ASSURANCE.[1]

BY T. D. LISTER, C.B.E., M.D. LOND.

THOSE of us who have duties in relation to accident and disease insurance have many questions other than medical questions to put to ourselves before we can give an opinion on any case before us. There are considerations of public health, of private character, of self-interest of classes and of individuals, that profoundly affect our decisions after we have had placed before us all the medical facts obtainable. Assurance problems demand of us that we shall never lose sight of the fact that the medical evidence is only one part of the whole evidence put before us. The medical part is certainly essential, but we have to form a judgment on the relative importance and inter-relation of the medical and the other facts.

Heredity alone opens up a number of problems that are by no means settled. We are far from differentiating between personal conditions that can be ignored if a person comes of long-lived stock and those which cannot be so ignored. We know very little about heredity, but we give impressions derived chiefly from our own experience. These are affected by our endeavours to hold the medical scales evenly in the assurance market between the buyer and the seller, the public and the office. This ignorance—I speak for myself—caused me once to try to conceive the assessment of a life as resembling an attempt to foretell the future course of a missile, of which we only observe the mass, direction, and speed for a short moment in its journey. This led me to the fanciful idea of vital-trajectories.

Vital-Trajectories.

An individual is conceived, and from that moment there is in existence a force, the resultant of a number of components, including the possible handicap of conceptional disease, that should convey the new body in a certain direction, to a certain distance. It will, bar accidents, "live," as we say, for a longer or shorter time. Accidents, including illnesses, may happen to stop its progress, either pre-natal or post-natal. In insurance we usually have to make a judgment long after birth, and after a brief examination, with insufficient data as to the past, and knowing nothing of the future, we presume to form an opinion as to a future history. Sometimes we can see the coming disaster, the crashing of the shell, more or less plainly; sometimes we have reason to fear its early occurrence from loss of momentum or what not; and often we see no reason why we should not advise a bet on its arriving at the limit of its range. This figure of speech could be pursued, through many variations, to enable us to use it to illustrate both seen and unseen obstacles in the way of the "life." It is the business of this society to endeavour to gather and diffuse knowledge of these obstacles to the smooth course of the body through life. We want to learn the effects produced by a clogging environment and habits, the damage done by passing through target-screens of acute disease occurring in its path, and the mode and date of the probable cessation of its flight. Some lives, as we all know, pass through attack after attack of acute disease, or accidents and operations, unimpeded, undamaged so far as we can see. Others have lost momentum permanently from slight affection before we see them. At the moment we can only endeavour, so far as heredity is concerned, to visualise the forces derived from the ancestry in a life before us, and the effect of the absence or the presence of hindrances to the full accomplishment of the span of life. To take tubercle, for example, a family history of recovered tubercle is sometimes as favourable a point in a proposer with a personal history of pleurisy with effusion, as the family history of deaths from tubercle is unfavourable.

With all the sources of error I have tried to suggest we have one great safeguard. That is, that in the head office at any rate, of an insurance company, we have to place lives in classes rather than to insure individuals. A fact to which I wish to call attention is that there are certain differences of practice among the offices. Perhaps, I should say, there are certain classes of risks which are more acceptable at some offices than at others, and some less. Most of us have heard, and perhaps said, "I don't like to insure such and such a malady."

Counsels of Perfection.

Here is a justification for the development of our work to endeavour to secure more uniformity of practice, but the very circumstances of life insurance preclude us from carrying out the counsels of perfection that have been urged upon us Ophthalmoscopy, otological observations, radiograms, have been recommended as preliminaries to insurance Our commercial friends will not accept them A proposer requires a policy, the office wants to sell him a contract The proposer must not be kept waiting, the office will not incur undue expense A force is introduced in this way which tends to lack of discrimination between the good and bad risks and to the broadening, fair or unfair, of classes of particular risks

---

[1] Abridged from the presidential address to the Assurance Medical Society delivered on March 3rd, 1920.

What, for instance, is the actual experience of mortality of the "running ear"? Is it best to group such cases with an all round addition, or should we insist upon the otologist's report on every case? Do we go far enough, on the other hand, in albuminuria? In 1910 Dr Hector Mackenzie suggested that a good many really assurable lives were refused on account of albuminuria I have, I confess, recommended many cases of albuminuria for acceptance, "with removable extras," after microscopical examination of the centrifugalised deposits I have also rejected many Delay seems to be less of an obstacle in these cases than it is in otorrhœa, or perhaps it is that the cost is less

Prophylactic Vaccination

Shall we, after the experience of the army, ask questions as to inoculation for diseases other than small pox by what are called "vaccines as a preliminary to acceptance? Should we be disposed to diminish the premium to the proposer who has been through the whole list of stock vaccines? It has been suggested recently that all the policy holders of a company should be offered free inoculation against the threatened recrudescence of influenza and its complications The office would pay, and was to make a large economy on the saving of claims thus produced The distinguished bacteriologist who made this suggestion scarcely appreciated the difficulties in his way

Infective disease, as all know, forms but a very small part of the total life risk I am anxious to see some day, when we get the decennial supplement to the Registrar General's report covering 1918–19—which will not be for 10 years, probably—whether the influenza mortality, including, if you like, respiratory diseases, has made such a big increase as to support an argument for inoculation as a preliminary to acceptance at ordinary rates I would like to see the mortality figures of the inoculated for comparison Still more important would be an inquiry as to the general prognosis of infective diseases nowadays

The Biological Evolution of Disease

The biological evolution of disease, a matter of great interest for the insurance companies, has as yet, not received enough attention The endocrine secretions have a close relation to this study Our difficulties as insurance advisers may become complicated by inquiries as to the health of the functions of many glands that we at present ignore, and we may be asked to ascertain whether the proposer regularly consumes a ration of some particular gland The insurance of cases of enlarged thyroid, whether attended with the symptoms of Graves's disease or not, is a matter which not infrequently comes before us We do not know much about their mortality, but my experience is that the outlook is not very bad, and that the majority of such cases are acceptable But I would like more information from those who have large experience of these cases over many years

Further, I want to know more about low tension I hinted in the discussion on Dr Otto May's recent paper on tuberculosis that the sphygmomanometer was useful in certain classes predisposed to tuberculosis or suffering from latent tubercle In some of these the only discoverable sign may be a low tension, and such cases with any family history of tubercle, I should regard with much suspicion The question of blood pressure has, I consider, some relation to the study of the endocrine secretions

The Effect of Alcohol on the Duration of Life

Alcohol is by no means exhausted as a subject for consideration We know that for certain select lives, with a very high standard of moral hazard in the risk, there is a low mortality among teetotallers, while Sir Dyce Duckworth in 1904 expressed an opinion in favour of the moderate use of alcohol both among the healthy and the sick The experiments upon which the case for total abstinence rests are chiefly reaction and discrimination time experiments They are perhaps, conclusive as showing the temporary depression of nervous and psychic rapidity of action due to doses of alcohol I submit that such evidence is no criterion as to the effect on life duration It may not be a good thing to be always energetic That a drug capable of producing depression of energy may produce annihilation of energy in larger doses is one thing but there are also drugs capable of producing exaltation of energy which may produce exhaustion All that I feel myself able to say is that excesses are bad in either direction Certainly many abstainers are drug takers, even if it only be their tea that they take To ascribe all the good effects on mortality, among certain excellent groups of lives, entirely to their abstinence from alcohol is unscientific, but inasmuch as total abstinence connotes other qualities making for longevity, it is therefore to be favourably regarded in assessment On post war affections, such as soldier's heart, malaria, dysentery, wounds, amputations, the reasoned guidance of physicians and surgeons, not only of war experience, will be of the greatest help to us Does rapid action of the heart over a prolonged period tend to cardiac or vascular degeneration earlier than if the heart pursues a placid course throughout? Are war neurasthenia and shell shock things which increase mortality now that we hope there is no chance of their recurrence? Should they be "rated up" when the signs have disappeared?

There is all the difference in the world between the clinical diagnosis and prognosis of the obviously ill, and the insurance diagnosis and *prognosis of the apparently well*

Some Difficulties Considered

One great blank in our work is the impossibility of finding out the after history of our insured invalids What especially we do not know is the after history of declined lives An organisation established by all the offices could do a great deal by asking for the return of the claim papers in all cases where the proposers were known to have been rejected or rated up at any time The results of our guess work could then be estimated by analysing such results

A great difficulty is to avoid being guided chiefly by 'impressions" Another is the shifting ground of advancing knowledge, for instance, the improving tropical risk The resulting tendency is always to broaden our work in life assurance The office can, and usually does take care of itself But we are not serving the office well if we reject lives which are assurable at a price In certain families death tends to occur from asthma, bronchitis, pneumonia, phthisis, and so forth, in others from arterio sclerosis, aneurysm, fatty heart, syncope What is the relation of such conditions to infections, notably hereditary and acquired syphilis in the latter group, or to gout, or to excessively strenuous living? There are opportunities for a great extension in our work in investigation, perhaps with actuarial assistance, of all these problems

ARSENIC IN SUGAR

A SERIOUS question arises in regard to the transport of foodstuffs when it is disclosed that arsenical or other poisonous consignments are packed amongst them There were several sufferers from arsenical poisoning at Haslemere this week owing to the leakage of a weed killer tin, the fluid reaching a barrel of moist sugar Some 60 persons were affected, but happily without fatal result, the circumstances being promptly investigated by the local medical officer, Dr R J Hutchinson, conjointly with Dr Spencer Low of the Ministry of Health It seems to us that it is most desirable that poisonous commodities—and arsenical weed killer is a very common one—should be consigned in hermetically sealed vessels, proof against the possibility of leakage The occurrence at Haslemere might have been much more serious than it was, and it is questionable whether those in charge of local transport should be allowed to convey goods with foods and powerful poisons together in close proximity

THE MEASUREMENT OF CARDIO VASCULAR DEPRESSION

AN interesting method of standardising the response of a patient to the joint influence of anæsthesia and surgical shock has been elaborated by Dr Charles W Moots and Dr E I McKesson[1] In order that an accurate observation may be kept on the pressure changes the cuff of a sphygmomanometer is kept in position during the operation and a stethoscope bound below it with elastic webbing Records are made from time to time and entered upon a graph The following table is laid down by the authors as a standard for classification —

Safe —10 to 15 per cent increase on pulse rate without change in pressure 10 to 15 per cent decrease in blood pressure without change in pulse rate

Dangerous —15 to 25 per cent increase in pulse-rate with 15 to 25 per cent decrease in blood pressure

Fatal —Progressively increasing pulse rate above 100 with progressively falling blood pressure of 80 or less systolic and 20 or less pulse pressure for more than 20 minutes

Their clinical work has convinced them that the final factor in shock is muscular exhaustion When a patient is heavily anæsthetised in order to obtain extreme relaxation, he is "half shocked," and often a very little trauma will be sufficient to produce fatal depression The value of anæsthetics in reducing surgical shock has long been realised The possibility of their becoming adjuvant to shock at a later stage raises important considerations, and the whole subject is well worthy of research

[1] Guy's Hospital Gazette March 6th 1920

THEATRE CHILDREN.

THE rules, dated Jan. 12th, 1920, relating to children licensed to take part in entertainments under the Prevention of Cruelty to Children Act, and the report of the Committee (Cmd. 484) on which they are based show that about 33 children under 12 years of age are thus employed in London, a number increased to 95 during the pantomime season. The rules lay down definite standards for the health and education of these children and the committee found them considerably superior in culture and intelligence to the average child educated in the public elementary school. The licensing depends in practice on the school medical officer, who has to file a certificate of fitness every three months, although, strangely enough, the committee had no medical representative nor was any medical evidence laid before it. According to the wording of the rules, any school medical officer in any area may be asked to certify. While in general the report and regulations are commendable, it is manifestly absurd to require on each certificate particulars of previous licences, lists of text-books to be used, certificates, photographs, reports of last head teacher on the child's educational attainments, and so forth. The thing would be funny if it did not entail so pathetic a waste of time.

THE PEOPLE'S REFRESHMENT HOUSE ASSOCIATION.

THE twenty-third annual report of this association shows a condition of steady progress. At the end of 1919 there were 150 licensed inns held by the association, and during the present year seven will be taken over, while negotiations are proceeding with the Cambridgeshire, Huntingdonshire, and Isle of Ely Public House Trust Association for taking over seven other houses all within easy distance of Cambridge. Ten houses at present held by the Derbyshire Public House Trust will also be taken over at an early date. Since January, 1916, the P.R.H.A. has assisted the Central Control Board (Liquor Traffic) in the management of seven important houses in a directly controlled industrial area. The financial statement shows that after writing off proportion of repairs to date, placing £4069 to depreciation reserve, and paying £1582 interest on loan stock, &c., the amount available for disposal is £13,217 18*s*. 11*d*. To encourage food production the potato clubs started in 1918 were continued in 1919, and prizes to the amount of £258 were awarded, while £494 were given to hospitals, village nursing institutions, and similar charities.

THE MEDICAL NEEDS OF TRINIDAD AND TOBAGO.

INSTRUCTION is to be drawn from the difficulties which arose in the medical administration of Trinidad during the year 1918.

In the first place, there was a good deal of sickness among the members of the medical staff, necessitating frequent changes and causing dislocation of the work. At the Port of Spain Colonial Hospital a nurses' home is an urgent necessity. The hospital accommodation was strained throughout the year, the average number of occupied beds being 345, while the authorised number is 340; at one time as many as 399 patients were accommodated in the wards. An out-patient department is badly needed, and an enlargement of the House of Refuge for aged and incurable poor patients who at present have to be treated at the Colonial Hospital. The principal causes of admission were enteric fever (445 cases and 83 deaths), malaria (331 cases and 22 deaths), pulmonary tuberculosis (235 cases and 118 deaths), and venereal disease (489 cases and 22 deaths).

Similar conditions of overcrowding existed at San Fernando, the next largest town after the capital. The hospital accommodation is for 123, but as many as 160 patients were sometimes under treatment in the wards. Here ankylostomiasis (477 cases) and venereal affections (301) were the chief diseases under treatment; the former disease (of which 29 cases were fatal) showed a large increase (154) over the admissions in 1917. A good water-supply and an efficient type of latrine, the use of which should be compulsory, are urgent necessities in the villages. Dr. E. A. Turpin, who reports on this hospital, considers that a mild anthelmintic dose (chenopodium oil or thymol) is far more reliable for diagnosing the condition than examination of the fæces for ova, the latter often giving negative results, though the patient is heavily infected. There were 123 admissions for pneumonia, of whom 50 died, 25 of these deaths occurring in October, when the disease was "epidemic in character and of a very virulent type"—in fact, influenza. In regard to the treatment of chronic amœbic dysentery and the best means of preventing its recurrence, as emetine given hypodermically does not get rid of the cysts, Dr. Turpin advises a combination of emetine-bismuth-iodide by the mouth, with emetine hypodermically and in large enemata, ol. chenopodium being also administered to expel the cysts; this combination has given good results.

At the Leper Asylum there were 502 inmates at the beginning of the year and 550 at the end, the daily average under care being 534. Of the 203 admissions during the year, 85 were inhabitants of Trinidad or Tobago, while 95 were immigrants from India. The admissions to the St. Augustine Hospital for yaws numbered 1299, more than in any year since the institution was opened, which has caused considerable inconvenience. Since the adoption of salvarsan treatment the number of admissions has been practically doubled (974 compared with 473, annual average). The average duration of stay in hospital, which was formerly 166 days, is now, with the use of salvarsan, only 51 days. The percentage of recurrent cases, which was formerly 12, has now been reduced to 5·4.

In his introductory observations Dr. F. A. de Verteuil, the acting Surgeon-General of Trinidad, draws attention to the numerous resignations which have taken place during recent years among the junior medical officers of the staff, which he considers due to the very meagre salary (£250 per annum) that is offered. As to this there can be no difference of opinion. It would be well for the colonial administrative authorities to give their immediate attention to this matter, as well as to the unsuitability of the quarters for medical officers and nurses that are at present provided.

A SECRET REMEDY BEFORE AN AUSTRIAN COURT.

Dr. Ottmar Reiner, a surgeon in Gracz (Styria), sued Kinsky Renard Maria, the world-famed opera-singer, for a fee of 50,000 crowns, the actress being willing to pay only 10,000 crowns, although, as Dr. Reiner alleged, he saved her life. The patient suffered from X ray burns, which defied every known treatment, and in consequence of the pain of which she became a morphinist. She then consulted Dr. Reiner, who succeeded in curing her entirely in eight weeks with the aid of an ointment, the secret of which he did not divulge. The actress's lawyer argued that the ointment was not the invention of Dr. Reiner, but that he inherited its secret from his grandfather. He reserved an exceedingly profitable secret monopoly for himself, which was contrary to the ethical duties of a doctor. The court accepted this argument, and decided to summon the ethical board of the Medical Society as to the justification of this exorbitant fee from a medico-ethical point of view. The board declared that to keep the composition of an ointment secret for the sake of material gain was contrary to medical ethics, and that Dr. Reiner had already been abundantly paid by the offered 10,000 crowns (£4000). Whereupon the court refused Dr. Reiner's appeal.

A POSTHUMOUS REQUEST.

Mrs. F. H. Seddon, of Clifton Down, Bristol, who died recently, left the following instructions: "That before my body be placed in the coffin the spine and spinal marrow of the neck shall be completely severed by a competent surgeon, to whom a fee of £25 is to be paid."

SCHOOL MEDICAL INSPECTION IN NATAL.

IN the report on School Medical Inspection in Natal during 1918, by Dr. A. B. M. Thomson, it is stated that, of the 1719 routine children examined as many as 646 required treatment—that is, 37·58 per cent. There was a general tendency to overclothe the children in some of the better schools; but allusion is made to the "prevailing fashion among the younger school girls. The object seems to be to show as much of the bare leg as possible, and this is accomplished by wearing very short skirts and still shorter socks. The result is grotesque, and in some cases immodest. Undoubtedly in every instance it is unhealthy, because it exposes a large surface of the body to extremes of temperature, and leads to chills and rheumatism. Why such an outrageous dress should be inflicted on children is more than mere man can understand." This very sensible observation might be made with regard to the dress of similar children in many London schools at the present day. It is said that "the amount of malnutrition has increased" in 1918; but only one child is recorded as being badly nourished, a girl 7 years of age; while 21 per cent. of the boys and 14·5 per cent. of the girls are returned as "medium," and all the remainder as "good." Food prices had risen, and wages had not increased in proportion. Free meals for necessitous children are provided by the Provincial Council. Dr. Thomson recommends the provision of a midday meal, which could be done for 4*d*. a day by the education authority, a much more nutritious dinner being afforded by centralised cooking than could be given by individual parents; he considers that "a universal midday meal at school would materially lessen backwardness among school children, and it would also improve their health and increase their happiness. In other words, it would pay." It is stated that "there were 14 cases of eczema, all of them being 'sores' (impetigo)." Some good recommendations are made as to diet; 37 per cent. of the boys and 30·2 per cent. of the girls had four or more decayed teeth, which, however, is an improvement on the previous year, when the percentages of dental defect were 43 and 39 respectively. Adenoids are met with, but much improvement has taken place, and parents are generally anxious to have them attended to. In 8·2 per cent. of the boys and 6·4 per cent. of the girls adenoids were found, compared with 13·7 and 10·4 per cent. in the previous year. During the year 222 students at native training colleges were examined as to physical fitness; 14·8 per cent. suffered from malnutrition, and in 17·5 per cent. the vision was defective; there were many cases of eyestrain, and the lighting in some of the classrooms was not satisfactory. Some students also seemed to be suffering from over-pressure.

RESCISSION OF RATS ORDERS: A CORRECTION.

THE last sentence in a note on this subject which appeared in THE LANCET of April 3rd (p. 794) should have read: The Rats and Mice (Destruction) Act, 1919, has rendered this memorandum obsolete, and it is now formally withdrawn.

Milroy Lectures

THE HIGHER FUNGI IN RELATION TO HUMAN PATHOLOGY.

Delivered before the Royal College of Physicians of London

BY ALDO CASTELLANI, C.M.G., M.D., M.R.C.P. LOND.,
PHYSICIAN TO THE TROPICAL HOSPITAL (MINISTRY OF PENSIONS); LECTURER AT THE LONDON SCHOOL OF TROPICAL MEDICINE.

LECTURE II.[*]

Delivered on March 2nd, 1920.

THE higher fungi may attack any organ and system of the human body, the integumentary system being the most frequently and the nervous system the most rarely affected. It would take too much time to discuss seriatim the numerous mycological affections of the various systems, and I will limit myself to only touching on the following so-called internal mycoses: 1. Thrush. 2. Broncho-mycoses. 3. Tonsillo-mycoses. 4. Certain mycoses of the nervous system and organs of special sense. 5. Certain mycoses of the uro-genital system.

THRUSH.

It is generally stated that thrush is due to the fungus *Oidium albicans*, Robin (Syn.: *Monilia albicans*, Robin). For many years, however, I have endeavoured to demonstrate that the ætiology of thrush is far from being so simple, and that this condition, at least in the tropics, is not caused by one fungus only, but by a number of different fungi, and that in reality the term thrush does not cover one affection, but a group of clinically similar conditions due to various organisms.

The fungi I have so far isolated belong to various genera and species—

- Class: *Fungi imperfecti.* Sub-class: *Hyphales.*
  - Order *Thallosporales*—Family *Oösporaceæ*, Saccardo.
    - Genus *Monilia*, Persoon—Several species.
    - Genus *Oidium*, Link—Three species.
  - Order *Hemisporales*—Genus *Hemispora*, Vuillemin—One species.
- Class: *Ascomycetes*—Sub-class: *Protoascomycetes*—Order *Saccharomycetales.*
  - Family *Endomycetaceæ*, Rees—Genus *Endomyces*, Rees—One species.
  - Family *Saccharomycetaceæ*, Rees.
    - Genus *Saccharomyces*, Meyen—One species.
    - Genus *Willia*, Hansen—One species.

Fungi of the Genus Monilia, Persoon.

These are the fungi most commonly found in thrush. As regards their botanical characters, it suffices to say, from a practical point of view, that these fungi are characterised principally by the following features. In the lesions the vegetative body (thallus) is composed of mycelial threads of rather large size often showing arthrospores and numerous free oval or roundish budding yeast-like forms; in cultures, especially on solid media, mostly roundish or oval budding elements are seen, while mycelial filaments are very scarce or absent. These fungi, as a rule, ferment with production of gas, glucose, and often other sugars. The only monilias I know of which do not attack any sugar or other carbohydrate are *M. zeylanica*, Cast., and *M. zeylanoides*, Cast.

There is little doubt that the original fungus *Oidium albicans*, described by C. Robin in 1853, belongs in reality to this genus, and its correct name is therefore *Monilia albicans* (C. Robin, 1853). There is little doubt also that the term *Oidium* or *Monilia albicans* has been used in the past to cover a number of different fungi, as proved by the widely different descriptions of it given by different authors. For instance, some observers state that the organism liquefies gelatin, others deny that it possesses such action. Certain authorities describe it as coagulating milk, others as having no action on this medium.

The more important Monilia fungi I have found in thrush belong to the following types:—

M. balcanica, Cast., ferments, with production of gas, glucose only.

M. krusei, Cast., ferments, with production of gas, glucose and lævulose.

M. pinoyi, Cast., ferments, with production of gas, glucose, lævulose, and maltose.

M. metalondinensis, Cast., ferments, with production of gas, glucose, lævulose, maltose, and galactose.

M. tropicalis, Cast. (Figs. 1, 2, and 3), ferments, with production of gas, glucose, lævulose, maltose, galactose, and saccharose.

M. guillermondi, Cast. (rare), ferments, with production of gas, glucose, lævulose, and saccharose.

M. macedoniensis, Cast. (rare), ferments, with production of gas, glucose, lævulose, galactose, saccharose, and inulin.

M. pseudotropicalis (extremely rare), ferments, with production of gas, lactose in addition to other sugars.

M. pseudolondinensis, ferments dextrin in addition to other sugars.

M. zeylanica, Cast. (Fig. 4), does not produce gas in any sugar or other carbohydrate. This group contains the following species: *M. zeylanica*, Cast., *M. zeylanoides*, Cast.

M. albicans, Robin, *sensu stricto* belongs to the metalondinensis type, and I have very seldom isolated it.

I should like to emphasise the point that a large number of fungi of the genus *Monilia* have not permanent sugar reactions, they often lose some of their original fermentative properties and can be trained to ferment sugars which they do not ferment when recently isolated, and therefore, for purposes of classification and comparison, such fungi should be investigated, using only recently isolated strains (see Table I.).

Fungi of the genus Oidium sensu stricto.—This genus is morphologically closely allied to monilia, and mycelial threads are very abundant both in the lesions and in cultures, and budding, yeast-like cells are rare. Fungi of this genus may occasionally induce an acid fermentation, but never produce gas in any carbohydrate. I have found fungi of this genus in certain cases of thrush in the tropics and in the Balkans, but so far not in England. I have isolated three species (Figs. 5, 6, and 7): *Oidium matalense*, Cast., *O. asteroides*, Cast., and *O. rotundatum*, Cast. It is interesting to note that I have found the same species in cases of mycotic tonsillitis and in the expectoration of certain cases of bronchitis, while I have observed *O. asteroides* also in the stools of certain cases of enteritis.

Fungi of the genus Hemispora.—The botanical characters of these fungi I have given in my first lecture. They are characterised by the presence of abundant mycelial hyphæ, some of which are *conidiophores*. Each *conidiophore* terminates into an ampulliform or sausage-like structure, which is called *protoconidium*. The *protoconidium* later divides into a number of spore-like segments, which are called *deuteroconidia*.

So far only one species of this genus has been found in cases of thrush, *Hemispora rugosa* (Fig. 8). This fungus was first isolated by me from a case of mycotic tonsillitis in 1910, and observed in a case of thrush by Pijper in 1915. Two varieties can be distinguished: one liquefying gelatin, the other having no such action on the medium.

Fungi of the genus Willia, Hansen.—These fungi are characterised by the peculiar bowler-hat shape of their ascospores. I isolated a fungus belonging to this genus in Macedonia from a case of thrush in a gipsy. In sugar broths it formed a thick pellicle containing air-bubbles.

Abbreviations.—A = acid. G = gas. C = clot (milk), clear (broth and peptone water). CTP = clear at first; then thin pellicle present. D = decolorised. P = peptonised (milk), pellicle (broth). ALK = alkaline. $\frac{\text{A}}{\text{ALK}}$ = acid, then alkaline. S = slight. VS = very slight. 0 = negative result—viz., neither acid nor clot in milk; neither acid nor gas in sugar media; non-production of indol; non-liquefaction of gelatin or serum, as the case may be. + = positive result, liquefaction of medium. In column headed "Colour," W = white, P = pink, Y = yellowish.

* Gelatin +, Serum +s. † Gelatin +. In all other instances gelatin and serum gave a negative result.

It produced gas in glucose and lævulose only. Cultures on solid media contained asci with 2–4 spores of the peculiar bowler-hat-like appearance. (Fig. 9.) The fungus seemed to be somewhat similar to *Willia anomala*, Hansen, but the investigation of it is not yet complete.

Fungi of the genus Endomyces, Link.—These fungi are on superficial examination similar to those of the genus *Monilia*, budding elements and mycelial threads being found in the lesions, and mostly budding elements in cultures. There is, however, a very important character which differentiates these fungi: in old cultures of endomyces asci are present. Only once have I come across a case of thrush due to a true endomyces, in Macedonia in 1917. I considered it to be *E. vuillemini*, Landrieu.

Fungi of the genus Saccharomyces, Meyen.—In the Balkans I found a case of thrush due to a typical saccharomyces, which I have only recently studied. Fungi of this genus are characterised by the vegetative body consisting only of budding elements, and by the presence of asci in cultures. The saccharomyces isolated by me ferments with production of gas, glucose, lævulose, galactose, maltose, and saccharose. It does not clot milk, which, however, may occasionally become acid. Gelatin and serum are liquefied.

Clinical Varieties of Thrush caused by Above Fungi.

I have always endeavoured to combine the laboratory and the clinical investigation of the cases of thrush observed, in order to see whether different groups of fungi are causing different types of the condition. In my experience two principal varieties of thrush may be distinguished clinically:—

1. *White, or white-greyish type.*—This is by far the most common, and in this country apparently the only one found. It is characterised by the cream-white colour of the patches.

2. *Yellow, or yellow-brownish type.*—This is characterised by the yellowish, occasionally brownish, colour of the patches.

The first type (or white type) may be caused by any species of the genus *Monilia* (except *M. zeylanica*, Cast., and *M. zeylanoides*, Cast.), by *Oidium matalense*, Cast., by *Endomyces vuillemini*, Landrieu, and by fungi of the genus *Saccharomyces*, Meyen, and *Willia*, Hansen. The second type (or yellow variety) is caused by *M. zeylanica*, Cast., *M. zeylanoides*, Cast., *Oidium rotundatum*, Cast., and *Hemispora rugosa*, Cast.

In conclusion, I should like to say again that thrush is not caused by one species of fungus only, the so-called thrush-fungus or *Oidium albicans*, Robin, as generally

Tonsillo-mycosis due to *Hemispora rugosa* stated. It is caused by a number of different fungi, some of which are botanically very far apart from each other, and belong to separate species, genera, and families.

Sprue.

Before leaving the subject of thrush I might say a few words on a very important tropical disease, which, according to many authorities, is ætiologically connected with thrush—namely, sprue. This tropical affection, very common in Ceylon, is characterised, as well known, by profound anæmia, progressive wasting of the patient, and white, frothy diarrhœa. Kohlbrügge first in 1901[1] ascribed the disease to the thrush fungus: *Oidium* or *M. albicans*. He made a very thorough histological study of one of his cases which ended fatally, and emphasised the fact that the fungi, in sections of the tongue, &c., had invaded the deep strata of the mucosa, the glands, and portions of the submucosa. These findings were speedily confirmed by other observers, and Le Dante in 1907 suggested for the disease the term of "Blastomycosis intestinalis." During my long stay in Ceylon I investigated the intestinal mycological flora of several cases of sprue, and I found that fungi were present almost constantly. I noted the following: *M. decolorans*, Cast. and Low, *M. intestinalis*, Cast., *M. fæcalis*, Cast., *M. insolita*, Cast., *M. tropicalis*, Cast., *M. enterica*, Cast., *Oidium rotundatum*, Cast., *O. asteroides*, Cast. I believed the monilias to be the probable cause of the frothy diarrhœa, but I did not agree with Kohlbrügge that they were the primary cause of the malady. Low came to the same conclusion as I did. Recently Kohlbrügge's theory has been supported in a series of publications by Bahr, Ashford, and others, while Sir James Cantlie has brought forward the hypothesis that it is a deficiency disease, and Sir Leonard Rogers and Nicholl the theory that it is a streptococcus infection.

I have made tentatively the suggestion that, as is the case with dysentery, the term sprue may perhaps cover several clinically similar but ætiologically different conditions: one might be of mycological origin, another of bacterial origin, &c.

BRONCHO-MYCOSES.

Bronchial affections due to the higher fungi are quite common in the tropics, and are occasionally met with also in temperate climates. They may be classified in several groups as follows:—

1. Causative fungus belonging to the genus *Nocardia*, Toni and Trevisan, or the genus *Cohnistreptothrix*, Pinoy: Nocardiasis.
2. Causative fungus belonging to the genus *Monilia*, Persoon: Broncho-moniliasis.
3. Causative fungus belonging to the genus *Oidium*, Link: Broncho-oïdiosis.
4. Causative fungus belonging to the genus *Hemispora*, Vuillemin: Broncho-hemisporosis.
5. Causative fungus belonging to the genus *Aspergillus*, Micheli, and *Sterigmatocystis*, Cramer: Broncho-aspergillosis.
6. Causative fungus belonging to a *Penicillium*, Link: Broncho-penicilliosis.
7. Causative fungus belonging to the genera *Mucor*, Micheli; *Rhizomucor*, Lucet and Constantin: Broncho-mucormycosis.
8. Causative fungus is a *Sporotrichium*: Broncho-sporothrichosis.

I have come across cases of all the forms I have mentioned. The severity of these affections depends a great deal on the variety of fungus present. If the condition is of nocardial origin the prognosis is very bad, if of monilia or oidium origin the outlook is less unfavourable, though certain cases terminate fatally. If the affection is caused by a sporotrichium, a hemispora, or in general by fungi which are rapidly influenced by potassium iodide, the prognosis is good.

I may perhaps be allowed to say a few more words about three of the varieties I have mentioned.

1. Broncho-moniliasis, and in connexion with it "tea-factory and tea-taster's cough."
2. Broncho-mucormycosis.
3. Broncho-aspergillosis.
4. Broncho-penicilliosis.
5. Broncho-nocardiasis.

Broncho-moniliasis.

This variety of broncho-mycosis was described by me in 1905 in Ceylon. The condition has recently been found in many tropical and subtropical countries, and even in the temperate zone. Pijper has described cases in South Africa, and Chalmers and MacDonald and Fahra had a number of cases in the Soudan and Egypt, while Iacono has found several cases in the south of Italy, and only a few weeks ago I found a case in this country. The condition appears to be caused by several different species of the genus *Monilia*, which I have described on other occasions (see also Castellani and Chalmers's Manual of Tropical Medicine, p. 1886).

Clinically, a mild type and a severe type of the malady may be distinguished, with, of course, a number of intermediate cases. In the mild type the general condition of the patient is good, there is no fever, and he simply complains of cough. The expectoration is muco-purulent, often scanty, and does not contain blood. The physical examination of the chest is negative or reveals only a few râles. The condition may last for several weeks or months, and may get cured spontaneously, or continuing, may turn into the severe type.

The severe type closely resembles phthisis. The patient becomes emaciated, there is hectic fever, and the expectoration is often bloody. The physical examination of the chest may show patches of dullness, fine crepitations, pleural rubbing. This type may be fatal.

The treatment consists in giving potassium iodide to which glycerophosphates and balsamics may be associated. It is interesting to note, however, that in certain cases potassium iodide has practically no beneficial action whatever.

Tea-taster's Cough.

In connexion with broncho-moniliasis, I may say a few words on the so-called "tea-taster's cough" and "tea-factory cough." In 1906 a young assistant in one of the big Ceylon firms, a tea-taster, came to consult me for a chronic cough, which he said had not yielded to ordinary treatment, and had been suspected by several medical men to be of tuberculous origin. He emphatically stated, however, that he did not believe it was tuberculosis. "I am merely suffering," he said, "from tea-taster's cough," an expression I had never heard before. The general condition of the patient was good, and the physical examination of the chest revealed only a few coarse râles. The microscopical examination of the sputum was negative for T.B.; instead I noticed microscopically some mycelial filaments and some yeast-like bodies. I inoculated several glucose-agar tubes and I grew a monilia fungus which, at the time, I believed to be an endomyces.

How did this patient get infected? Tea-tasters, in order to judge of the quality of the various teas, not only taste infusions, but often fill their hands with the tea-leaves and bury their noses in them, sniffing them up; in this way a certain amount of tea-dust enters the nasal cavities. Now if one examines tea-dust in Ceylon one finds that it contains fungi of the genus *Monilia* constantly, of the genera *Aspergillus* and *Penicillium* frequently, and of the genus *Oïdium* occasionally. A peculiar streptococcus is also very often present. The same organisms are not rarely found in the nasal cavities of tea-tasters, and when bronchial symptoms appear in them monilia-like fungi are present in the expectoration. It is probable therefore that the so-called tea-taster's cough is a moniliasis, especially as a guinea-pig, in the nostrils of which I insufflated tea dust regularly, died with symptoms of chronic bronchopneumonia.

What I have said about "tea-taster's cough" applied to a great extent to the so-called "tea-factory cough." For many years planters have noted in Ceylon that the coolies doing work in the tea-factory, where the leaves are dried and there is a large amount of tea-dust floating about, after some months become weak, lose flesh, and often have a cough with muco-purulent expectoration. The planters have found by experience that these coolies must be taken away from the factory and sent to work in the field, and then the symptoms slowly disappear. I have examined some of these coolies, and their expectoration practically always contains fungi of the genus *Monilia*. I have little doubt, therefore, that the so-called tea-factory cough is a *broncho-mycosis and probably a broncho-moniliasis.*

---

[1] Arch. f. Schiffs u. Tropen Hygiene, 1901, No. 12.

Broncho-mucormycosis.

While I was in Macedonia a Serbian was sent to me with the diagnosis of T.B. The patient was very anæmic, very weak, and was losing flesh rapidly; slight fever at night. Sputum muco-purulent. The examination of the chest revealed nothing except a few coarse râles. Examination of the sputum for T.B. constantly negative; instead, a few mycelial segments were noticed on several occasions. Glucose agar tubes and other media were inoculated and a fungus was isolated, which at first showed cultural characters somewhat monilia-like; in subcultures, however, the characters of a mucor appeared; a yellowish ovoid-shaped "columella," sporangium globular, about 50 micron in diameter, of yellowish colour; spores elliptical, smooth.

How did this patient get infected? It is interesting to note that he was in charge of horses and often had to remove horse-dung. As is well known, *Mucor mucedo*, L., is extremely common in horse-dung.

Broncho-aspergillosis.

I have seen several cases of this condition in the tropics—a case in an island in the Adriatic, another in Macedonia. These two cases have been diagnosed as T.B.; from one *Aspergillus fumigatus*, Fresenius, was grown; from the Macedonian case a fungus very similar or identical with *Sterigmatacystis nigra*, Cramer, was isolated. In France, as well known, a peculiar bronchial aspergillosis is common among pigeon breeders (*gaveurs de pigeon*), who fill their mouths with grain and blow it into the mouths of the pigeons. The grain contains spores of various aspergilli and after a time most *gaveurs* become infected.

Broncho-penicilliosis.

A Serbian soldier was sent to me with the diagnosis of T.B. He was wasting and had serotine fever. Expectoration muco-purulent, occasionally bloody. Examination for T.B. constantly negative. A few mycelial threads present. A fungus was grown with the characters of *Penicillium crustatum*, L. Potassium iodide acted satisfactorily.

Broncho-nocardiasis.

In the Balkans I have observed one case of this condition, in the tropics several. The case seen in the Balkans was a young Serbian with all the symptoms of tuberculosis of the lungs; great loss of flesh, serotine fever, bloody expectoration; the physical examination of the chest showed patches of consolidation, crepitations, and pleural rubbing. The sputum contained at times some very small, whitish granules, composed of very thin branching filaments, Gram-positive, and partially acid-fast. The fungus was easily grown on maltose and glucose-agar, and in subcultures also on ordinary agar. The cultures had at times a pink-reddish colour. Gelatin was liquefied. No treatment was of any avail.

TONSILLO-MYCOSES.

Mycotic affections of the tonsils are far from being rare, especially in tropical countries. The more chronic conditions, especially of the crypts, due to nocardia-like and leptothrix-like fungi, have been known for many years, but I should like to call attention to certain acute mycological affections which I have described during the last 15 years, and which not rarely have been mistaken for diphtheria—viz., tonsillar moniliasis, tonsillar oidiomycosis, and tonsillar hemisporosis. (Fig. 10.)

Acute tonsillar moniliasis.—CASE 1.—Singhalese girl, about 11 years, admitted to the Infectious Diseases Hospital of Colombo with the diagnosis of diphtheria. There were white patches on the tonsils, uvula, and soft palate. The temperature was rather high (102°); the pulse frequent and of low pressure. There was swelling of the lymphatic glands at the angle of the jaw. The child developed symptoms of broncho-pneumonia and died three days after admission. (Anti-diphtheria serum was given twice by the physician in charge of the hospital.) The microscopical and bacteriological examination of the patches for the Klebs-Löffler bacillus, carried out with the usual technique, using serum-media, &c., remained negative. No bacteria of any kind were seen in the specimens directly taken from the patches, but numerous mycelial and conidial elements of a fungus were present. On serum and glycerine agar media no colonies of diphtheria or other bacteria. The fungus had all the characters of *Monilia tropicalis*, Cast.

CASE 2.—A young European lady, 22 years of age, became suddenly ill with sore-throat at one of the Colombo hotels. Her medical attendant suspected diphtheria, and called me to see her in consultation. When I examined her the temperature was 101°, pulse 98; she complained of difficulty and pain in swallowing, both tonsils and uvula were covered with white creamy patches. Preparations made from the patches revealed an enormous number of yeast-like organisms and a few cocci, while no bacilli of any kind were present. This, of course, was sufficient to exclude diphtheria. On glucose agar tubes a fungus grew in pure culture with all the characters of a monilia. This monilia rendered milk slightly acid, and then decolorised it completely; did not liquefy serum or gelatin. On serum it induced a narrow zone of black discoloration all round the growth.

Acute tonsillar oidiosis.—European, 25 years of age; since several years in Ceylon. In November, 1914, was taken ill with severe sore-throat, difficulty in swallowing, and high fever (104° F.). When I saw him, 12 hours after onset, both tonsils were covered with a white exudation, but not the uvula.

The microscopical and bacteriological investigation showed absence of the diphtheria bacillus, while a fungus was grown with the botanical characters of an oidium. Further investigation revealed it to be very similar to *Oidium matalense.*

Acute tonsillar hemisporosis.—I am indebted to Dr. Spaar for the clinical notes of the following case. European planter, admitted to the Kandy Hospital on May 2nd, 1913. The illness had started two weeks previously. Temperature on admission 101°. Complained of severe pain in the throat and of difficulty in swallowing. Flushed face; felt extremely weak and exhausted. Voice thick and nasal. Swallowing painful and difficult. Fluid regurgitated through nostrils. There was a profuse flow of saliva. The muscles of the neck were rigid, submaxillary glands enlarged and painful. The patient was unable to open the mouth wide. Tongue thickly coated and dry; soft palate swollen. Greyish membranes were present on the left tonsil, left anterior pillar, and soft palate. Diphtheria antitoxin (2000 units) injected the same day into the flank and a spray of hydr. perox. prescribed. During the next four days the general condition improved, but the white-greyish membrane in the cleft between the left tonsil and the left anterior pillar was still very evident. Nine days after admission there was still a small whitish patch visible, but the patient felt quite well and was discharged the following day.

Dr. Spaar sent swabs taken with all possible precaution to me for examination. In smears made from the swabs no bacilli were seen, a few cocci were present, and numerous large mycelial segments of a fungus. Serum tubes and glycerine-agar tubes were inoculated as usual, and, given the presence of mycelial threads, also several sugar agars. The serum and glycerine-agar tubes did not show any growth of the diphtheria bacillus; instead there was growth of a fungus with a peculiar crinkled surface which I had found previously in 1909 in a case of bronchitis. I was uncertain about its classification, and placed it temporarily in the genus *Monilia*, and called it *Monilia rugosa*. However, I sent cultures of the fungus to Professor Pinoy, of the Pasteur Institute, who, after a long botanical investigation, came to the conclusion that the organism belonged to the genus *Hemispora*. The correct name of the fungus became therefore *Hemispora rugosa* (Cast.). During the war I have seen several cases of acute tonsillo-mycosis in the Balcanic-Adriatic zone, and recently a case in Paris, and a case in this country.

MYCOTIC AFFECTIONS OF THE NERVOUS SYSTEM AND OF ORGANS OF SPECIAL SENSE.

In 1904, from the pus of a cerebellar abscess, I grew an extremely delicate fungus, a nocardia which was Gram-positive and partially acid-fast. No club-like formations were present in microscopical preparations. This nocardia grew comparatively well on sugar media, very slowly and scantily on ordinary agar. On all media the colonies had a black pigmentation. Abscesses of the brain and cerebellum due to true actinomyces have been described by several authors. In cases of general infections due to saccharomyces, monilia, and endomyces-like fungi, abscesses containing such fungi may be found in the brain and spinal cord, as in other organs of the body.

Organs of special sense.—Mycological affections of the eye may be classified as follows: Due to species of genus *Nocardia* and genus *Cohnstreptothrix*, ocular nocardiasis. Due to various species of—

$$\left.\begin{array}{l}\text{Genus } \textit{Saccharomyces}\\ \textit{Cryptococcus}\\ \textit{Endomyces}\end{array}\right\} = \text{Ocular blastomycosis.}$$

Due to fungi of genus *Monilia*, ocular moniliasis.
Due to fungi of genus *Oidium*, ocular oidiomycosis.
Due to fungi of genus *Aspergillus* and *Penicillium*, ocular aspergillosis and penicilliosis.
Due to fungi of genus *Sporotrichium*, ocular sporotrichosis.
Due to fungi of genus *Glenospora*, ocular glenosporosis.

The commonest mycological affection in Ceylon is moniliasis. I have seen several cases in Singhalese children of a conjunctivitis apparently due to a monilia; the conjunctiva was highly inflamed, there were photophobia and purulent discharge. The microscopical examination showed in addition to pus cells, numerous yeast-like bodies. No gonococci or any other bacteria were present. Agar and various sugar-agar tubes were inoculated with the pus, and a monilia fungus was grown. It is to be noted that not rarely, at least in the tropics, spores of various fungi are found in the slight secretion which so often collects at the angles of the eyes even in normal people, but these spores do not, apparently, usually give rise to any symptoms.

Rhinomycoses.—Yeast-like and other fungi are often observed in the nasal mucus; they may play only a saprophytic rôle or they may give rise to an inflammation of the mucosa. In Colombo a little native boy was brought to me by his parents, who stated that he had been suffering for the last three months from repeated attacks of severe sneezing, and that they had observed that on blowing the nose minute black dots were coming out in the mucus. Microscopical and cultural investigations showed this case to be one of aspergillosis due to *A. niger*. In the literature cases of aspergillosis of the nose due to *A. glaucus* (De Bary) and *A. fumigatus* (Fresenius) have also been described.

Otomycoses.—Various fungi may be present in the external auditory canal without causing any symptom. In some cases, however, the fungus multiplies abundantly, and may be the cause of a local inflammation or may apparently facilitate the formation of a wax plug. In several cases I have found a monilia which I have called *M. rhoi*. It two cases of otomycosis I have found a fungus belonging to the family *Mucoraceæ*, *Lichteimia ramosa* (Lindt., 1886). It was present in great quantity, and the patient complained of tinnitus aurium and deafness. It is interesting to note that this fungus is found often in the nasal mucus of horses, and both my cases were Tamil *muttus* (horse-keepers). Various authors (Siebenmann, Boke, Huckel, &c.) have recorded cases due to *Lichteimia corymbifera* (Cohn), *Rhizomucor septatus* (von Bezold); Maggiora and Gradenigo found *Saccharomyces ellipsoides* (Rhees) in a case of chronic otitis media. The same authors found a new species of saccharomyces (*roseus*) in the Eustachian tube.

Aspergillomycosis of the ear is comparatively frequent; I have seen several cases in Ceylon, apparently due to *A. fumigatus* (Fresenius); Cramer observed *A. niger* (von Tiegham); Wreden, *A. flavus* (De Bary); Siebenmann, *A. repens* (De Bary); and *A. nidulans* (Eidam). Fungi of the order *Basidiomycetes*, family *Ustilagineæ*, have also been observed; *Ustilago carbo* and *Tilletia levis*. Of the order Hyphomycetes, *sensu stricto*, *Tricothecium roseum* (Persoon, 1801) has been observed in a few cases.

I may here mention that the best treatment I have found for the various forms of otomycosis is syringing with hydrogen peroxide 2 parts and alcohol 1 part.

CERTAIN MYCOSES OF THE GENITO-URINARY SYSTEM

Urethritis of hyphomycetic origin.—In the tropics and in the Balkans I have come across several such cases, which in my experience may be classified as follows:—

1. Discharge whitish or yellowish—the causative fungi generally belong to the genera *Saccharomyces*, *Monilia*, *Cryptococcus*, *Oidium*.
2. Discharge dark brownish or greenish-black, or black: These cases are generally due to fungi of the genus *Cladosporium* (*Foxia*), *Aspergillus*, *Penicillium*.
3. Discharge reddish or pinkish: Generally due to the red-pigment-producing fungi of the genera *Cryptococcus*, *Saccharomyces*, and *Monilia*. At times two organisms are found: a higher fungus such as a monilia, and in symbiosis with it a red-pigment-producing coccus or bacillus.

I may quote the following cases illustrating the various clinical types I have mentioned:—

Mycotic urethritis with yellow discharge.—A young Serbian officer in Macedonia consulted me for a fairly abundant purulent urethral discharge. The patient was greatly distressed: he was engaged and believed he was suffering from gonorrhœa, though he denied having exposed himself to infection. I examined the secretion: no gonococci present; instead a very large number of yeast-like cells and a few mycelial filaments could be seen. The cultural investigation showed presence of a monilia very similar to *M. krusei*. I prescribed a mixture containing pot. iod., soda bicarb., glycer., syr. of tolu, and irrigations with a solution of perchloride of mercury 1 in 20,000. The discharge disappeared completely within ten days.

Black mycotic urethritis.—An old Tamil coolie came to the Colombo Clinic in January, 1906, complaining of black urethral discharge dating from several months back. He stated that he had not had sexual contact for several years. The secretion was blackish and contained numerous small granules, which on microscopical examination were seen to consist of mycelial threads and spore-like bodies. Various sugar media were inoculated and a fungus was grown, producing a black pigmentation, and very similar also in other characters to *Cladosporium mansoni* (Cast.). In two other clinically similar cases, one in a native and the other in a European, I found aspergillus-like fungi.

Red discharge.—A little Singhalese boy, 6 years old, was brought to my clinic in Colombo by his parents because they believed he was passing blood from the urethra. The discharge, examined microscopically, consisted of some leucocytes and numerous budding cells. Several sugar-agar tubes were inoculated and a red-pigment-producing cryptococcus was grown. The child was given an alkaline mixture, and instillations of diluted glycerine of borax were carried out. This, however, did not improve the condition. Urethral injections of a solution of perchloride of mercury, 1 in 20,000, were then made and a speedy cure resulted.

Very similar mycological conditions of the female genito-urinary organs may be observed, and cases of vaginitis and vulvo-vaginitis due to fungi of the genus *Monilia*, *Cryptococcus*, *Aspergillus*, *Penicillium*, and *Cladosporium* have been recorded; and as the same fungi are found in urethral and vaginal discharge, it cannot be excluded that in certain cases these mycological infections may be contracted by sexual intercourse. When the monilia-like and saccharomyces-like fungi are the causative agents two clinical varieties may be distinguished. In some cases thrush-like patches are present on the mucosa (vaginal thrush); in others no such patches are present, but the discharge is purulent, very thick, and, in my experience, these latter cases have not rarely been mistaken for gonorrhœa. In 1914 the surgeon in charge of the Colombo *Lying-in Home had* a case in which a pelvic operation was urgent; a thick purulent vaginal discharge was, however, noted, and he felt inclined to postpone the operation. A specimen of the discharge was sent to me with the request to examine it for gonorrhœa. No gonococci; however, were found, instead an enormous amount of mycelium and conidial elements. Further investigation revealed the fungus to be *Monilia pinoyi*, Cast. Cases of hypomycetic vaginitis are found, though not so frequently, also in temperate climates, and Taylor and myself have placed on record several such cases. It must be added, however, that finding fungi in vaginal mucus is nothing new; one may read in THE LANCET of as long ago as 1840 (p. 448) a paper by Wilkinson with the following title: "*Some Remarks upon the Development of Epiphytes with the Description of a New Vegetal Formation found in connection with the Human Uterus.*"

A Presidential Address

ON

MATERNITY AND CHILD WELFARE WORK.

Delivered at the First Meeting of the Society of Medical Officers of Maternity and Child Welfare Centres at Bedford College, Regent's Park, on March 26th, 1920,

BY HECTOR CHARLES CAMERON, M.D.CAMB., F.R.C.P.LOND.,

PHYSICIAN AND PHYSICIAN IN CHARGE, DEPARTMENT OF DISEASES OF CHILDREN, GUY'S HOSPITAL.

LADIES AND GENTLEMEN,—My first duty is to thank you for the honour you have done me in electing me as the first president of this society. I hope that as a society it will soon display a vigorous existence, with a momentum of its own, owing no more than is necessary to the exertions of any particular individual or group of individuals. That, I think, is the criterion of healthy existence in such a society as ours. Nevertheless, in order to set the ball rolling there is need, in the first instance, for the help of a small number of enthusiasts, some in London and some in those other parts of the country where, from time to time, it may be decided to hold meetings. I hope that ultimately, all over the country, there may be arranged pleasant and informal meetings between the medical men and women who are interested in various phases of maternity and child welfare, meetings at which the clinical aspects of the work may be freely discussed, meetings from which we may catch something of each other's enthusiasm and by which the practice of each of us may benefit from the experience of all. For such coöperation between us the time, I think, is already overdue. I need not say that I am a strong believer in the possibilities for good which are inherent in the movement for maternity and child welfare, nor am I in the least inclined to regard the results which have been achieved so far as altogether insufficient or unsatisfactory. Great progress has been made. Visible success has crowned efforts which have deserved it. This country of ours enjoys certain advantages over all other countries which have made possible the surprising developments of the work in the last few years. In the first place, in no other country has the Government shown so much appreciation of the importance of the subject or extended the same recognition and assistance. In the second place, in no other country was there already in existence before the movement started a Public Health Service in any way comparable in scope, organisation, and efficiency to that which was established here, and which was able to take under its control from the first a very large part of the management of the new movement. I think the possession of these two advantages accounts very largely for the rapidity with which the work has progressed during the last few years—a rapidity of which we may well be proud; and so, if in what I have to say I speak no more of the success the movement has achieved, but confine myself to deploring some things which seem to me *a source of weakness and an impediment to progress*, you will understand, I feel sure, that it is not because I do not recognise the value of what has been accomplished, but only because I desire to see the movement forward accelerated.

THE CONFUSION BETWEEN CURATIVE AND PREVENTIVE WORK.

Now, in the first place, I believe very strongly that success is denied to a very large number of centres because the distinction between curative and preventive work is not recognised. Under the name of "Infant Welfare Work" more often than not there are combined three separate branches of activity. Many infant centres do not confine themselves to the care and inspection of healthy children, to supervising their management, diet, and clothing, to encouraging breast-nursing and perfecting its technique, and to educating the mothers to an appreciation of health and pride in it. They prefer to act, or are forced to act, as well, at the same place and time, as centres for treatment, especially inviting the attendance of children already suffering from malnutrition or infection. With these two different and entirely incompatible functions is commonly combined a third. They act as distributing centres for doles of milk, food preparations, or clothing, dispensed free of charge or at reduced prices. Now, in my opinion, *it is very easy to recognise the deplorable result of this admixture of functions. The mothers and the* general public *are confused in their notions* as to the object and aim of the welfare centres. I should like to see displayed in every centre a statement that we doctors are generally powerless to undo all the ill-effects of chronic infantile ailments, but that, with the help of the mothers, we can do much to prevent them. It was because of the complete and proved failure of hospital out-patient departments and dispensaries in this *respect that we were led to investigate the possibilities of preventive institutes, and found them of* value. If sick and ailing babies are to be seen side by side with those that are thriving it is to be expected that the sick will monopolise time and attention to the exclusion of the healthy, and inevitable that many mothers of healthy children will then ask themselves of what use it is to continue attendance. I fear that mothers generally have little idea of the true purpose of a centre. To too many of them they are places to which they may take the baby for advice and treatment when a long process of faulty management has finally resulted in infection. I am not unmindful of the needs of the children whose health is permanently below par. No doubt both the sick and the whole need a physician, and the same organisation and the same building may have to be used for both purposes. But in all that we do it seems to me necessary that we should see to it that the distinction between the healthy and the ailing is clearly impressed on every mother. We may define the healthy infant as the infant who, upon the breast or upon some suitable artificial diet, proves itself capable of a steady gain in weight and of acquiring its several functions in due time. Such an infant we may be confident is acquiring day by day an increasingly high resistance against infective disorders of all sorts. If the weight fails to increase during a period of some weeks, or has fallen for any reason more

[illegible] Field Library

than 25 per cent. below the average, or if progress is persistently unsatisfactory in any other way, then, I think, that child should fall from the category of the healthy to that of the sick. I think the hours of attendance of the sick should be different, and that the mother should understand the reluctance with which we have to transfer her child from the one department to the other. Only when the child has again shown its power to thrive and gain in weight, without medicinal treatment or any profound modification from the standard diet of health, should it be readmitted. The whole atmosphere of the two services must be different. Among the healthy children the note must surely be that of congratulation, and admiration, and delight. When the child has to be transferred to the treatment clinic there may be hope and encouragement, and sympathy and a concentrated effort to produce better results, but there can be little of the light-heartedness that is so essential in the other. A blue ticket for health and a pink one for failure with different days of attendance, and the contrast in the whole tone and atmosphere will, I think, do more than anything else to help the mothers to realise what we are aiming at. Yet the Ministry of Health in its latest Memorandum, while expressing the hope that the essentially preventive aspect of the work will not be lost sight of, suggests that the syphilitic infant may well be treated in the welfare centre—a sort of death's head at a feast. To mix the sick with the healthy is to obscure any good effects obtained; to cast a shadow of disease and death over what was meant to be a place of health. I make the same criticism of the observation wards annexed to centres. I know that they are said to be for infants only slightly ill, but who can tell the slight illness of to-day in the young infant from the fatal illness of to-morrow? In these observation wards there must occasionally be failures and deaths, and an infants' centre is the last place which should be associated, in the minds of the public, with death. Nor can the reputation of a centre support such a disaster. A centre serves a comparatively small area of adjacent streets. One or two deaths will evoke comments and criticisms which may outweigh the credit earned by a year of patient work. Indeed, I think the observation ward should be removed as far as possible from the centre, and should have no apparent connexion with it. Before the child is admitted it should have ceased to be numbered among the healthy infants attending the centre.

THE CENTRE AS A DISTRIBUTER OF GIFTS AND DOLES.

To the other functions which it has become the rule for the infant centres to assume that of a distributing centre for milk or clothing or various drugs and preparations, for which no charge, or only a nominal charge, is made, there are, to my way of thinking, also very grave objections. It is not to the good of the cause that mothers should be attracted by what they may be given. I have heard of instances where mothers attend more than one centre to receive double gifts. I have heard of instances where mothers have been attracted away from one centre to another because it has more to give. The centre should know of the provision of these gifts and should recommend suitable cases to apply in order to participate, but there should be nothing to suggest that their provision is a bribe offered to mothers to attend centres. Are mothers at one centre to be urged to make garments and taught to do so, and at another are they to be given a complete outfit for 6*d.*?

"The centre is worth as much as the presiding physician" is a saying of Budin, quoted with approval by the Ministry of Health in the Memorandum referred to above. I can imagine nothing more calculated to lower the worth of "the presiding physician" than the suspicion that the mothers are there, not in response to what he or she has to offer, but in order to participate in the bounty. If drugs and widely advertised foodstuffs are to be dispensed, then it is to the drugs and foodstuffs that credit will be given. But if a mother does not realise that any good result is due to her own exertions, guided and inspired by the physician, then our labour is in vain. In the past few years our work has moved rapidly. In these two particulars especially I submit to you the movement has been in the wrong direction, and the original aim and purpose of our work have been lost sight of.

THE RELATION OF HEALTH VISITOR AND MEDICAL OFFICER.

In the second place, I desire to consider shortly the part which is nowadays played by trained health visitors and trained nurses in infant welfare work and their relation to the medical officer. Here, also, there has been, of recent years, very great development, and no one, I think, would venture to say that the direction has here been retrograde. It is right that these workers should be trained as highly as possible, and should know something of the rudiments of hygiene, physiology, and dietetics. To very many of them, in addition, is given a keen understanding, tact, sympathy, and unfailing patience. But while medical officers recognise their value and admire their efficiency, we must be careful, at the same time, to define very accurately the nature of their duties and their responsibilities. They must not be regarded as adequate authorities in one of the most difficult branches of medicine. Unless their work is controlled and inspired by a medical officer with knowledge infinitely greater than their own, then that work will not often prove efficient, and not infrequently all their efforts will do more harm than good. We must not be misled by the analogy of the midwife, who has to be trained only in certain definite manipulations and can be left to carry on her work unaided to a great extent. I would point to the work of Dr. Truby King as an instance of the inspiration which the trained health worker and trained nurse can catch from the expert medical officer. Now, if I may say so, I think that some of Dr. Truby King's work was open to criticism. To my way of thinking he did not sufficiently differentiate between preventive work and curative or therapeutic work, and he seems to me at times apt to ascribe to his dietetic prescriptions success which was really to be ascribed to the high standard of hygiene and nursing in his hospital, and, still more, to the power of his own dominating personality acting upon the mothers. With him it was often the prescriber rather than the prescription which was effective. But no one with whose work I am acquainted approaches near to Dr. Truby King in his power of vitalising the routine work of his assistants and subordinates, and of filling them with his own confidence and power for good. Dr. Truby King, if he were here, would not resent my remarks I feel sure. His work has been so great that it can allow each one of us to deduct what is displeasing to him without doing it much damage. Now, no one, I think has studied the work of others more carefully than Dr. Truby King. In all countries, in the States, in this country, in France, in Germany, he has sought and found inspiration in the work of others, and when he has found it he has handed it on to all who are associated with him. Let there be no mistake about it, the success of the whole movement depends, not so much on the training of health visitors, so much discussed at present, as upon the training, capacity, and enthusiasm of the medical officers. The value of the visitor depends upon the use the medical officer can make of her. We have behind us a Ministry of Health which is sympathetic, and which, if it could always do what it wanted, would, I think, always act wisely. We have a magnificently organised Public Health Service to work with; we have a better educated and a more understanding body of health visitors and trained nurses than any other country, and with all these advantages, have the medical officers of centres as a whole throughout the country occupied the position they ought to occupy? I know that there are innumerable and admirable exceptions, but in far too many instances it is taken for granted that anyone will do for an infant centre. The medical officers at present are a heterogeneous body. Young and recently qualified officials, who know little of children in sickness and still less of children in health, whose opinion can carry little weight, either with the mothers or the health visitors, men skilled in general practice, who find the absence of pathological interest unstimulating, medical officers of health who, though very well versed in the study of faults of environment, have less knowledge of the common reactions of the child to these faults, and whose manifold duties only permit them to maintain a nominal control over the health visitors who are left to pursue the work according to their own ideas. None of these is likely to conduct an infants' centre satisfactorily. Still less is the young practitioner who finds the income which can be culled from perfunctory attendance at one or more centres useful to live on while experience is acquired in some speciality which is more attractive. From none of these, and they are far too numerous, will the work gain credit.

THE DIFFICULTIES OF THE WORK.

But I wish to speak only of those of us—happily the greater number—who are in earnest in our endeavour. Our task is very difficult. There is no speciality more neglected in our schools and our universities than that of the study of childhood. It is a subject which it is difficult to learn, difficult to teach, and difficult to write about. The literature is not adequate to the theme. Certainly the text-book for medical officers of centres has yet to be written. It is not open to many of us to tour the country and visit other centres in search of inspiration and knowledge or to indulge in a wander year abroad. But I feel sure it is due to the relative isolation in which we work that so little clinical observation of value has proceeded from infant welfare centres, and that the advice given at different centres is often so flatly contradictory. We must urge the institution of undergraduate and post-graduate courses, though I am not at all clear who is well fitted to conduct them. Salaried appointments are now so numerous that a special diploma in child welfare must shortly be instituted and carry with it better pay. But above all I think we should join together for free discussion among ourselves. We have the reputation of a young speciality to make, and there is no good blinking the fact, it is not made yet. We are not yet equal to our opportunities. To deal wisely and successfully with each mother and each child calls for professional gifts of the very highest order. To determine, in each case where success is hanging in the balance, how far inherited tendencies or congenital weakness is responsible; how far dietetic errors, whether excess or quantitative faults in the construction of the diet; how far faults of management and handling; how far infection and of what parts—all this demands a wide experience. Moreover, since it is through the mother and by means of her alone that we can work effectually, the study of the mother must be as intimate and careful as the study of the child. She must be inspired with full confidence in us; she must be allowed free speech, and every word that she says is of importance if only we can find the key to the riddle of her cryptic sayings. Always she has observed aright; seldom can she describe what it is that she has observed, and to this she must be helped. Only when she has had her say is it the turn of the medical officer to expound and draw the moral. The explanation offered should fit all the facts, and it should fit them so accurately as to carry conviction. Let me finish with a concrete example to illustrate my meaning. A child suffers with constipation and pain on defæcation, with loud and prolonged crying when put to stool. As the mother talks one learns that the same resistance is shown to taking food. Although urged and coaxed, the child resolutely refuses to eat meat, or greens, or milk pudding. On being put to bed there is crying and resistance, and sleep is refused for many hours. One learns, too, that the so-called constipation is quite uninfluenced even by the strongest purgatives, unless actual diarrhœa is produced. On the other hand, when the child visited an aunt in the country, the mother of a large family, the constipation disappeared for the time being, to relapse on his return to London. The mother is much distressed by the child's complaint, and shows a disposition to cry even when talking over it. She has no other children. The so-called constipation and painful defæcation are here but one of many instances in the daily life in which that child shows the common symptom of nervous unrest in childhood, "negativism." Habitually he does the opposite to what he is so urged and appealed to to do. His little mind has been concentrated on the difficulty. His mother's over-anxiety has communicated itself to him. The action and interaction between mother and child have produced a neurosis which can easily be overcome if matters are explained and helpful suggestions are made to the child by a mother whose confidence has been restored. In that complaint of constipation how numerous are the points that we must explore. We have to try to determine if there has been lack of training and want of routine, or whether there has been excess of training, excess of insistence, and over-anxiety, as in the instance quoted. Or, again, is the constipation symptomatic of inanition and underfeeding, or is it due to faults in the construction of the diet, such that the fermentative processes in the intestine are too little developed and the putrefactive processes encouraged? Or is it more a question of what Dr. A. F. Hurst calls "dyschezia"—difficulty in the mere muscular act of defæcation from abdominal distension and general muscular malnutrition? To control this and many more difficult disturbances a routine dose of olive oil or syrup of figs will certainly not be sufficient.

CONCLUSION.

To deal with the hundreds of such problems which present themselves in our daily work requires understanding and requires time. Without free speech on both sides, from mother and from doctor, nothing will emerge. It is easy to pour out stereotyped good advice on points of hygiene and diet; it is easy to laugh at or deplore ignorant, fanciful prejudices of the mother; it is easy to dabble in laxatives and cough mixtures, to confiscate all dummies and most prepuces—easy, but quite ineffective. To be understanding with the mothers, to inspire and make useful the work of assistants, to train oneself to greater usefulness—none of these things are easy. Can we not help each other best by free discussion amongst ourselves?

THE TREATMENT OF SYPHILIS BY THE ANTISYPHILITIC SERUM OF QUERY.

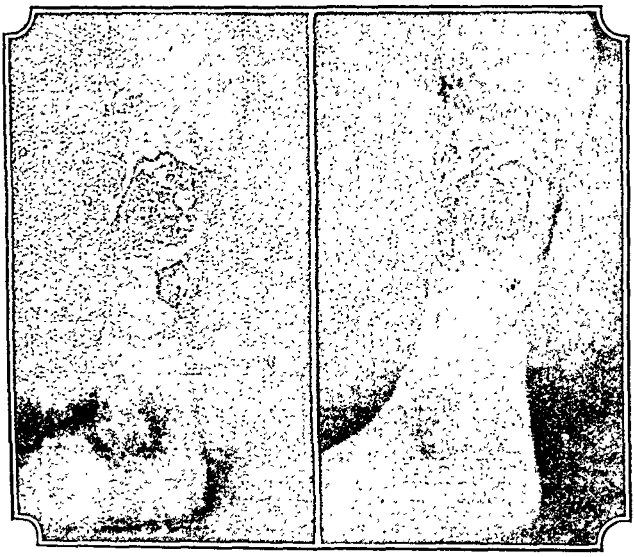
BY J. DOBRIANSKY, M.D. VIENNA AND PETROGRAD;
J. H. SEQUEIRA, M.D. LOND., F.R.C.P.,
PHYSICIAN TO THE SKIN DEPARTMENT OF THE LONDON HOSPITAL
AND
THEODORE THOMPSON, M.D. CANTAB., F.R.C.P.,
PHYSICIAN TO THE LONDON HOSPITAL.

THE value of mercurial preparations in the treatment of syphilis is undoubted, but their action is limited to certain stages in the course of the disease. The utility of mercury in the later manifestations of syphilis of the nervous system, such as tabes dorsalis and dementia paralytica, is very slight; not only does it fail to retard the progress of these diseases except in the very slightest degree, but it also fails even to give relief to the more obvious and distressing symptoms, such as lightning pains, progressive optic atrophy, or ataxia.

Salvarsan and its various preparations have, in our hands, been equally ineffective. While in the early stages of syphilitic infection salvarsan has a markedly destructive action on the syphilitic virus, it often fails entirely to prevent relapses, and later involvement of the nervous system is only too frequent. Not only are the later nervous manifestations of syphilis resistant to mercury, salvarsan, and the iodides, but certain gummatous ulcerations of the skin are equally unaffected, and may be treated for months without benefit by the usual remedies.

In view of the remarkable results reported from France of treatment of syphilis by Dr. Query's serum, a trial of the serum was made in the dermatological department and in cases of nervous disease at the London Hospital. Dr. Query states that his serum is prepared by inoculating monkeys with the filtered cultures of the organism of syphilis on bouillon. When the serum of the monkeys gives a strong positive Wassermann the animals are bled and the serum is collected and preserved in ampoules. Metchnikoff and Neisser had attempted to prepare an antisyphilitic serum by inoculating monkeys with the culture of Schaudinn's spirochætæ, but Query used the toxin prepared from filtered broth cultures.

The following cases were treated with Query's serum after complete failure of the recognised methods of treatment to relieve their symptoms. The relief of symptoms produced by the serum was marked, but it is, of course, impossible to speak of the permanence of the cure until the cases have remained under observation for some years.



FIGS. 1 and 2.—Showing condition of ulceration before and after treatment with Query's serum.

CASE 1. *Gummatous ulcers of the leg of long standing, with hyperkeratosis and deafness.*—M. R., aged 69, first attended the dermatological clinic of Dr. Sequeira for tertiary syphilitic ulceration of the left leg on Dec. 12th, 1917. Hyperkeratosis around the left ankle was well marked. The patient was very deaf. She was treated by injections of salvarsan, neokharsivan and galyl, and in all received 11 injections between Dec. 14th, 1917, and Sept. 9th, 1919. In all 4·5 g. of arsenobenzol were injected. During each period of injection she had rest in bed and local treatment with fomentations and antiseptic dressings. From Dec. 21st, 1917, to Dec. 4th, 1919, she received in addition mercury and iodides internally. Comparison of photographs in December, 1917, and January, 1920, showed that no progress had been made in the healing of the ulcer. The patient was still very deaf and the hyperkeratosis round the left ankle was still present.

Treatment with Dr. Query's serum was commenced on Jan. 28th, 1920, when the serum was injected subcutaneously over the right biceps; the patient was not put to bed. A dry dressing was the only local treatment and the patient continued her ordinary avocation of charwoman. By Feb. 11th 20 injections of serum had been given and new photographs were taken, one of which (Fig. 2) may be compared with Fig. 1, taken before treatment with the serum was started. The larger ulcer is now filled up with red firm granulation tissue and has a dry glazed surface. The smaller ulcer is now flush with the surface and is smooth and dry to touch. The hyperkeratosis around the left ankle is markedly less, and in addition the patient's hearing has now become normal.

Dr. Sequeira made the following note on March 3rd, 1920. "This case had proved intractable to treatment by intravenous injections of arsenical compounds and by mercury and iodides internally. The improvement which followed the injections of Dr. Query's serum was remarkable, the ulcers are filled up and contracted, but the most striking feature was the recovery of the patient's sense of hearing. In view of these observations I am anxious to extend the use of the Query treatment to other cases of this intractable type."

CASE 2. *Tabes dorsalis with pronounced ataxic symptoms.*—B. G., aged 47, contracted syphilis in 1891. For the past ten years he has suffered from severe lightning pains in his lower limbs and occasional incontinence of urine. For the past four years he has had great difficulty in walking and can just hobble about with two sticks. Romberg's sign is very marked. When his eyes are closed he is quite unable to stand and falls over at once. He showed the typical tabetic gait, the knee-jerks were absent, and Argyll Robertson pupils present. The Wassermann test on Jan. 15th, 1919, was positive. A long course of mercury and iodides had failed to give any improvement and the ataxia was getting rapidly worse.

Starting from Feb. 14th, 1920, 5 intrathecal and 20 hypodermic injections of Query's serum were given. On March 14th there was a marked improvement in the patient's gait. He walked quite easily without his stick at a good pace. Romberg's sign was absent and he walked easily up and down the ward with his eyes closed.

CASE 3. *Tabes dorsalis with intractable lightning pains.*—J. H., aged 52, had suffered for ten years with violent darting pains in the legs, so severe that she had threatened to commit suicide. She had had a long course, over two years, of mercurial and iodide treatment. From August, 1919, to January, 1920, she received nine intravenous injections of salvarsan. The pains were no better; in fact, were steadily getting worse. On examination in February, 1920, the knee-jerks and ankle-jerks were found to be absent. The Wassermann reaction was strongly positive. The pupils were normal. She had had one miscarriage and no children. The only way the patient could obtain relief from the pain was by taking 7 gr. tablets of pyramidon. She took as a rule 35 g. a day to keep the pain under control. After seven injections of Dr. Query's serum the frequency and severity of the pains had markedly diminished, so that she was able to get through the whole day without resorting to the pyramidon. Her general condition had also improved.

Remarks.

For this preliminary note on the treatment of syphilis by Query's serum cases have been selected with prominent symptoms of the tertiary stage which have proved resistant to the recognised methods of treatment. The manner in which these intractable symptoms have been at once relieved by Dr. Query's serum is most striking, and, in our opinion, the serum deserves a thorough further trial in the treatment of the tertiary stage.

CENTENARIAN.—The death of Mrs. Sarah Evans, Llandysiliogogo, South Wales, aged 102 years, is announced.

LITERARY INTELLIGENCE.—Under the title of "Diathermy in Medical and Surgical Practice" Dr. Claude Saberton, honorary radiologist to the Harrogate Infirmary and to the Royal Bath Hospital, Harrogate, has written a guide to students and practitioners who wish to master the technique. The book is announced by Messrs. Cassell and Co. for early publication as an addition to the Modern Methods of Treatment Series.

RECURRING SARCOMA OF THE SMALL INTESTINE.

BY W. H. BATTLE, F.R.C.S. ENG.,
SENIOR SURGEON, ST. THOMAS'S HOSPITAL.

ONE of the latest and most informative papers on the subject of sarcoma of the small intestine is written by Dr. John Speese.[1] It is probable that the round-celled growths form about 50 per cent. of the various forms in which it appears, and the site is usually the ileum. From the fact that an actual closure of the lumen of the bowel is seldom met with, and the contents of it can pass until a late period, operation, which is usually for obstruction, is done when the disease is advanced, and the tumour, which has a tendency to drop into the pelvis, is only discovered when the patient is on the operation table. Its progress before discovery and pelvic position lead to involvement of the bladder in many.

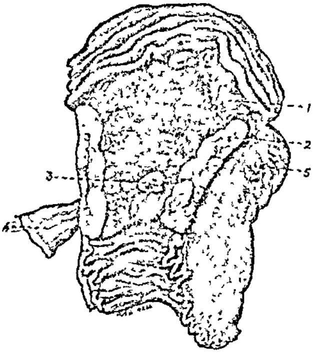
The importance of intussusception in the previous history is recognised, for many cases are published in which the intussusception was started by a growth. Kassmeyer collected 284 instances of this, of which 85 were malignant—59 carcinoma and 26 sarcoma. The symptoms are, however, usually chronic, and not those which are pathognomonic of the ordinary intussusception. In the case described below no tumour was found, nor did the sarcoma develop at the site of either of the attacks of intussusception. In the second attack a thickening was found, of an inflammatory character, at the apex of the intussusception, but when operation was performed 5½ months later for the growth it had not increased but diminished in size.

First attack of intussusception.—F. R., a girl, aged 8, was admitted to St. Thomas's Hospital on May 17th, 1913, with abdominal symptoms. For 24 hours she had suffered great pain in the abdomen, with frequent vomiting. Nothing had passed by the bowel during that time. She looked pinched and was evidently very ill. Temperature 100° F., pulse 100, respiration 24. She was subject to constipation. Examination of the abdomen showed a movable irregular mass in the right side; the iliac fossa below felt empty (signe de Dance) and was tender on pressure, but the abdominal wall was everywhere soft. Examination per rectum showed nothing abnormal. The abdomen was opened through the right rectus muscle (separation of fibres) and a large ileo-colic intussusception reduced with some difficulty after it had been brought outside. A hard button-like patch was left at the apex. She left on May 30th, recovery having been uneventful.

Second attack of intussusception.—On June 28th she returned from a convalescent home. Next day she had abdominal pain and vomiting; the bowels acted twice, but there was no slime or blood in the motions. The attacks of pain were severe and intermitting, causing her to roll about and cry out. The abdomen was rather distended. There was no visible peristalsis. On the 30th the bowels had not acted, although a glycerine enema had been given. In the afternoon the abdomen was reopened along the line of the old scar. The small gut was considerably distended and there was some clear serous fluid in the peritoneum. The mesenteric glands were enlarged. The intussusception was 2-3 ft. above the ileo-cæcal valve and about 4 in. long. It was easily reduced in part; the last portion was, however, much thickened, and a complete reduction was impossible, firm adhesions extending between the peritoneal surfaces. The intestinal contents passed this section with difficulty. Lateral anastomosis above and below this point was performed. The mucous membrane at the loop when examined through one of the incisions appeared somewhat swollen and sloughy. There was no evidence of tubercle, and von Pirquet's test was negative. She left the hospital well on July 26th.

The subsequent history of this patient is most interesting.

First excision of growth.—On Dec. 14th of the same year she came to the ward in which she had previously been a patient to request permission to be present at the usual ward festivities at Christmas. Whilst at the hospital she had an attack of abdominal pain and vomiting. Examination showed the patient to be suffering from some degree of distension of the abdomen, with peristalsis. A history of similar attacks over a period of three weeks was obtained. She was detained, and an operation performed the same afternoon. The line of the previous incisions was selected as it was not very strong. Some thickening could be felt under the upper end of the scar, and this proved to be the apex of the intestine forming the part which had been short-circuited at the second operation. There were one or two adhesions between the omentum and other parts, and when the pelvis was explored a tumour was found which was adherent to the summit of the bladder. It was some distance from the point of lateral anastomosis, encircled the small bowel, but did not quite occlude its lumen. The wall of the bowel above and below could be pressed into it, its shape, internally, resembling that of a dice-box. There was a bag of omentum adherent to it. (See figure.) The mesenteric glands were enlarged over a large area. After extension of the incision in the abdominal wall it was found possible to cut away the growth from the summit of the bladder, the wall of which was then sutured. The portion of gut affected by the growth was excised and the incision carried into the mesentery so as to remove as many glands as possible, and an end-to-end anastomosis carried out. The glands were much too numerous for a complete operation. The liver was normal. The small intestine above the growth was dilated and congested, that below smaller than normal, but there had evidently been no complete obstruction. There was a good deal of shock after the operation, but the bowels acted on the 17th, and there were no abdominal symptoms.



Primary round celled sarcoma of the ileum (The Acute Abdomen, p 254) 1 Raised edge of growth, not hard or everted. 2 Base extending to and involving peritoneum 3 Area which had given way. 4. Omentum closing opening. 5 Part cut away from bladder. Messrs. Constable and Company have kindly supplied the illustration.

Mr. Shattock reported that the growth was a round-celled sarcoma. At one point the growth had necrosed and here the omentum was adherent externally, so preventing extravasation of contents. On Jan. 20th, 1914, exploration was again performed to see if it was possible to excise any of the enlarged glands, but although some of them were smaller they were extensively affected, and one or two nodules of growth could be felt. Ten days later the use of Coley's fluid in increasing doses was commenced. She left for a convalescent home at Shooter's Hill (D'Erlanger), the treatment was continued by Dr. J. G. Duncanson, and she improved and put on weight. The patient was examined from time to time, and although there was no apparent disease in the abdomen it was considered advisable to readmit her with the view of a further course of Coley's fluid. She was under treatment from Jan. 1st to March 31st, 1916. There was some reaction to Coley's fluid, but nothing excessive. She was readmitted on July 14th, 1916, complaining of abdominal pains of a colicky nature, without vomiting, which came on about once a fortnight. In addition, examination of the abdomen showed the presence of several nodules the size of acorns, also increased resistance in the lower part and towards the right.

---

[1] Annals of Surgery, May, 1914, p. 727.

Second excision of growth.—As it appeared probable that there was growth causing some obstruction an exploration was done five days later. A large mass, involving the small intestine about 6 in. from the cæcum, was found in the right side of the pelvis. This was apparently a recurrence which had spread from the lymphatics or glands bordering on the former section of mesentery, there being a swelling larger in the mesentery than the portion which encircled the intestine. As a resection of the growth with a wedge-shaped piece of the mesentery involved division of the bowel close to the ileo-cæcal valve, it was thought best to close both ends and join the lower end of the ileum by lateral anastomosis to the lower part of the cæcum. Many glands were scattered about the mesentery, and these were the nodules which had been felt through the abdominal wall. There were no separate nodules anywhere independently of the glands, and the bladder was normal. The lumen of the gut was narrowed to the size of a little finger. This patient has been kept under observation, and the resident assistant surgeon, Mr. P. H. Mitchiner, tells me that there is no evidence of recurrence at the present time (March 30th, 1920). She has grown considerably and enjoys good health, but the abdominal wall on the right side is thinned from atrophy of the rectus muscle.

Remarks.

Although it was recognised at the first operation that the growth was a sarcoma, and that the glands were secondarily affected, these enlargements were so generally diffused that any attempt to extirpate them would have been hopeless and probably fatal. It would have involved removal of many feet of intestine, and there was a possibility that dissemination of growth in the glands was not so extensive as appeared. Another reason against doing more was the presence of one or two lumps in the peritoneum, which appeared to be growths of a character similar to the original one. An interesting feature in the case is the delayed recurrence, its removal, and the unusual prolongation of life which has followed treatment. Some credit for this (I am of opinion) must be attributed to the use of Coley's fluid after operation. Even now, nearly seven years since the beginning of her abdominal history, she appears in good health. The illustration shows the value of the omentum in intestinal perforations.

ERRATUM.—In the last issue of THE LANCET, p. 876, in an annotation on Dr. F. G. Cawston's paper on the "Treatment of Bilharzia Disease," Dr. Cawston is alluded to as the first Streatfeild research scholar, but no lecture has yet been delivered under the Trust.

WARNEFORD HOSPITAL, LEAMINGTON.—Owing to the serious state of the finances the governors of this hospital have decided to adopt the principle of payment by patients. A committee has been appointed to decide what form the innovation should take, but it is understood that it will be on a purely voluntary basis, respect being paid to the means of the patient. Last year out of 1026 patients treated only 29 showed their thanks by monetary contributions.

INFANTILE DIARRHŒA AND VOMITING:

THEIR PROPHYLAXIS AND TREATMENT.

BY G. DOUGLAS SHERWOOD, M.B., B.C. CANTAB.,
LATE HOUSE SURGEON AND OBSTETRIC HOUSE SURGEON, MIDDLESEX HOSPITAL.

AT this time, when our country is faced by the urgent necessity of repairing the ravages of war, any subject bearing upon the preservation of infant life becomes of the utmost importance. The object of this paper is to show how those distressing and dangerous complaints, diarrhœa and vomiting, may be controlled in the nursery by a regime of cleanliness as nearly allied to that of the operating theatre as the conditions will allow. Having access to the records of a home for children where these principles were put into practice, I have had good opportunity of studying the results of their adoption.

The diseases of infancy are among the most trying by which the practitioner is faced, and perhaps of all these diseases the two which form the subject of this thesis are the most difficult. In themselves they are by no means always mortal, but if prolonged, as so often happens, they are apt to lead to serious damage to the alimentary tract which may have a fatal result.

The Causation of Diarrhœa and Vomiting.

The great majority of the diseases of infancy and childhood are caused by bacterial infection. At the same time opinions expressed in text-books as to the infective nature of infantile diarrhœa are very divergent, while the infectivity of vomiting receives practically no attention. I intend therefore to deal first with diarrhœa and its treatment, and afterwards to produce evidence of the infective quality of vomiting and to describe the management of such cases.

The following authors may here be quoted to show the divergence of opinion mentioned above.

Ralph Vincent[1] states: "Epidemic diarrhœa is in no sense of the word an infectious disease and cannot be conveyed by contagion."

Frederick Taylor,[2] and earlier writers,[3] make no mention of infection, but attribute the disease to a variety of causes such as food and teething.

Savill[4] attributes it to various causes, but does not specify infection particularly.

Holt[5] gives five forms of diarrhœa, the fifth being headed, "Diarrhœa of Infective Origin," under which head he says: "The source of infection may be from without, bacteria being introduced with the food or water or accidentally; or it may be from within, where the non-pathogenic bacteria normally or frequently present in the intestines develop pathogenic properties."

Osler,[6] in a paragraph on the relation of bacteria to enteritis in children, says: "In infantile diarrhœa the number of bacteria that may be isolated from the stools is remarkable. Brooker has discriminated 40 varieties, the greatest number of which were found in cases of cholera infantum. The two constant forms noted above (*Bacterium lactis aerogenes* and *Bacterium coli commune*) do not disappear in the diarrhœal stools. No forms have been found to bear a constant or specific relation to the diarrhœal fæces, such as the two above mentioned do to the healthy milk fæces, the bacteria of the *proteus* group are most frequent, and possess pathogenic properties. All the varieties develop and produce important changes in the milk, which have been dealt with fully by Brooker in his exhaustive monograph (Johns Hopkins Hospital Reports, vol. vi.). This author concludes that in the diarrhœa of infants 'not one specific kind, but many different kinds of bacteria are concerned, and that their action is manifested more in the alteration of the food and intestinal contents and in the production of injurious products than in a direct irritation upon the intestinal wall.' "

Eric Pritchard[7] says: "The commonest cause of diarrhœa is the development within the bowel of an abnormal bacterial flora."

Ballard[8] considers that the essential cause of diarrhœa "is intimately associated with the life process of some micro-organism not yet detected, captured, or isolated."

Investigation of Results of a Strict Regimen.

We have, then, a variety of opinions on the subject. The records of the home mentioned above (Upwick Vale Home, Eastbourne), opened in 1892 and continued until 1916 (25 years), where an average of 17 infants, from 1 month to 2 years old were lodged, fed, and clothed every year, show that in the first three years diarrhœa was seldom absent, and six deaths from that cause occurred. For the remaining 22 years no case of diarrhœa originated in the home, and there was not a single death from that cause.

How can this remarkable change in the incidence of the disease be accounted for? During the third year a very strict system of dealing with the children was established and rigidly adhered to, with the exception of certain occasions mentioned later. This system was as follows:—

All new cases were isolated on arrival until such time as it was certain that their motions were normal. A special room, provided with washing apparatus and slop sink, was set apart to which all babies had to be taken whenever the napkins required changing, and the room was regarded as much as an unclean place as the w.c. used by the adults. As the napkins were removed and placed immediately in a disinfectant, the nates were washed and bathed with a disinfectant, the nurse washed and disinfected her own hands and those of the child, and then put on the fresh napkins. A special nurse was detailed for this duty, and she was not allowed to take part in the preparation and distribution of food to the children. The food was kept in a larder and was not allowed in any room used by the children except at meal-times. The food up to eight months consisted of whole milk, water, and sugar, mixed in proper proportions and sterilised. After eight months or even earlier bread, oatmeal, potatoes, gravy, skimmed milk, and dripping and bread were given. Orange juice was given regularly, when the antiscorbutic and growth-encouraging properties of fresh fruit became known, though their use was empirical at that time. The mothers were provided with a basin of disinfectant for use at night when changing the napkins and before feeding the baby.

From the time of the establishment of this system, apart from new admissions, there was absolutely no diarrhœa in so far as the system was rigidly adhered to. On two occasions a temporary matron allowed some relaxation of the rules, when diarrhœa at once appeared. On this being discovered the rules were again strictly enforced, and within 72 hours the diarrhœa disappeared. No form of medicinal treatment beyond an initial dose of castor oil was found necessary.

In the cottages attached to the home, where infants from 2 to 5 years old were sent, the same routine was observed though the supervision was not so strict. Only one epidemic of diarrhœa started there, and on investigation it was again found that some relaxation of the rules had been allowed, and the children were attending to themselves after defæcation. The children were at once paraded, and it was found that all the clothes that came in contact with the nates were soiled with fæcal matter. The soiled clothes were taken away and new provided, and the system of washing and disinfection again established. The epidemic stopped absolutely in 48 hours, with no other physic than a dose of castor oil.

Here we have surgical cleanliness applied to the nursery for the prevention and treatment of diarrhœa, with the result that diarrhœa is stamped out without the aid of drugs.

From these facts we can but conclude that the diarrhœa of infants is not only infectious but autogenous, and that by the enforcement of surgical cleanliness and isolation of duties it can be avoided and checked.

Having come to this conclusion, after a brief summary of the system, it may be well to consider some of its chief points in detail. These points are five in number. They are:—

(1) The food was kept in a larder and, except at meal-times, was out of all contact with the children and their service.

(2) A separate room was used for the changing of the napkins and, where possible, a separate nurse for toilet.

(3) The nates were washed and bathed with a disinfectant.

(4) The nurses' and babies' hands were disinfected.

(5) The napkins were immediately placed in a disinfectant.

The significance of (1) is self-evident, and would be hardly worthy of note were it not that babies' food is so frequently exposed to the risk of contamination.

With regard to (2), though the adult is provided invariably with a w.c., the infant has frequently to use its combined larder, living room, and dining room for the purpose, and hence has an ever-present source of infection.

(3) and (4) I have not been able to find any author on this subject or on medicine in general who has pointed out the fact that, with no more than the usual precautions taken in the cleansing of the nates after defæcation, whether in the adult or the infant, and, however carefully carried out, the odour of fæces can be detected on the hand used. This is true in the case of the infant even if the greatest care is taken by the nurse, when removing and folding the napkins, not to bring her hand in the least contact with fæcal matter which may be visible on the napkin. It may also be observed that wherever the napkin is placed even for a few moments, with whatever care taken that no visibly contaminated part comes in contact with the surface on which it rests, this surface takes up the odour of fæces. The hands of the nurse as soon as she touches the napkin to remove it become a source of infection, as may any part of her dress which may come in contact with them. Infection from these sources may reach the food or mouth of the infant. To wash the hands is easy and therefore is insisted on, but to change the dress every time the napkin is changed is asking too much of the nurse; hence she must not come in contact with the infant's food. The baby's hands need washing not only after it has its napkins changed but at frequent intervals, as it is by them that septic matter most frequently reaches the mouth.

(5) The significance of placing the napkin in disinfectant is, to my mind, of great importance, apart from the fact above mentioned, for reasons based on the opinion of some competent authors on the ætiology of the disease. Ralph Vincent says: "The disease is most prevalent and most fatal in the third quarter of the year; the higher the temperature of the late summer the greater the prevalence, particularly if high temperature be associated with little rain." Ballard[8] states that "the essential cause of diarrhœa resides ordinarily in the superficial layers of the soil, where it is intimately associated with the life-history of some micro-organisms; ...... that the vital manifestation of such micro-organisms are dependent, among other things, perhaps principally, upon conditions of season." Holt[6] tells us that "Observations in a large New York dispensary extending over ten years showed an enormous increase in diarrhœa, rising from February (289 cases) to July (12,468 cases) and falling by the middle of October (1723 cases)."

These statements are in accordance with the commonly observed rule that infantile diarrhœa is more frequent in the hot months. During the hot dry months the fæcal matter is more rapidly dried and reduced to dust, which is easily disseminated by draught and wind. It is obvious that the disease may become more widespread in the summer months. It may be noted in this connexion that Ballard[8] remarks that "such micro-organism is capable of getting abroad from its primary habitat, the earth, and having become air-borne, obtains opportunity for fastening on some non-living organic material." It is possible, in view of the above arguments, that the earth is not the original habitat from which the micro-organism becomes air-borne.

Conclusions as Regards Diarrhœa.

Considering again the relative importance of the five points given above, we see that the larder is but a means of preventing contamination of food by germ-laden dust and flies, and hence infecting the child; the separate room is but a matter of treating the child with the same decency and care as is meted out to the adult. If the washing of hands and nates were neglected, though the neglect would leave open a grave source of infection to the *individual* child, in the hot dry months the nates and hands are always damp to a greater or less extent with perspiration, and hence the fæcal matter does not so readily dry as to form a great danger to others. But the placing of napkins in disinfectant puts the largest and most easily dried source of infection of the community in general completely out of court, and it is for this reason that I consider this point of greater importance than the others as far as the safety of the many is concerned. It is interesting here to note that Holt[5] states that "the enormous increase in the number of cases occurring in the summer months does not have reference to any single form of diarrhœa, but to all forms"—a conclusion which, I think, adds emphasis to this point, since the dried fæcal material will disseminate many micro-organisms that inhabit the bowel.

Vomiting.

Having considered in detail the system as applied to diarrhœa, the similar system adopted at the home for the management of vomiting may now be considered. I do not refer to the simple regurgitation of almost unaltered food due to repletion, but the foul, acid vomiting which is so dangerous to the child and distressing to those who have the care of it. The system was as follows:—

Any child vomiting acid vomit was *immediately* removed from the nursery by the person noticing it and taken to an isolation room; its clothes were removed and the child bathed completely. When this had been done it was put into clean clothes. No milk was given for several hours, and the mouth was washed out at frequent intervals with a solution of borax in water. This sterilisation of the mouth is essential, as otherwise the infected mouth would infect the sterile milk.

A further possible source of infection were the spots of clean milk which get unavoidably splashed on the child's clothing during feeding. As a prophylactic measure, when the children's clothes were laundered they were, before being ironed, rinsed in borax and water; this precaution is particularly necessary in the case of bibs.

The use of this system provided a means whereby this dangerous complaint was held completely in check. Considering that the means used were those employed for the avoidance of bacterial infection and that they were effective, it may be urged that this is an indication of the infective nature of the disease.

In connexion with this point the possibility of the parent or nurse as a source of infection has to be considered. It seems horrible to suggest that any of these people may be a cause of so dangerous a complaint in their offspring or charge, but unclean hands or face, a foul mouth, or otorrhœa may well cause a disaster to the child. A case in point arose at the home. A child arrived in a pitiful condition due to gastric and intestinal disturbance, and in course of the routine was isolated and placed under the strict system of the home. As the child did not benefit in the usual manner, all possible causes for the persistence of the trouble were investigated. It was found that the mother was devoted to the child and was constantly kissing it. When examined she was found to have a mouth full of carious teeth. A promise was extracted that she would not kiss the child, and her teeth were attended to. The child's rapid recovery was the sequel.

If the result of the system as a whole is not proof of the infective nature of the diseases under consideration, this case gives proof of it as nearly as possible without bacteriological investigation.

Surgical Cleanliness Adapted to the Nursery.

Here, then, we have a system, for the principle governing that for diarrhœa and vomiting is the same, which controls two of the curses of infancy, and it is nothing more than the adaptation of surgical cleanliness to the everyday life of the nursery. It may be objected that the trouble involved renders the system inapplicable to the private patient. But of all people the private individual needs most training in the principles laid down in this paper. Of modern institutions which deal with babies, the great majority have trained nurses or matrons who insist on a standard of cleanliness in dealing with the babies being maintained. But in the home circle it is surprising what negligent and disgusting habits are indulged in. Who has not seen the mother or nurse who sucks the nipple of the bottle or comforter before giving it to the child? And there is the still more disgusting practice frequently used, though rarely in public, as the other is, of inserting the finger into the napkin to ascertain if the baby has passed water or defæcated, after which, whether the answer is in the affirmative or negative, the hand is by no means always washed before it handles the bottle or breast to feed the baby. These and similar practices, such as the above system is designed to combat, are used frequently in the lower classes, and are by no means entirely absent in the better class nurseries.

Experience shows that if it is explained to those in charge of the child that such practices may start disease, and that the adoption of the system, though apparently a troublesome one, may really be a saving of trouble and danger in the end, it is gladly adopted and soon becomes a matter of routine.

Its apparent effect on the death-rate from all causes is notable. I have worked out figures for comparison to the best of my ability from the figures given in the last Registrar-General's (1916) Report for Infant Mortality in the whole of England and Wales for the years 1892–1916—taking, that is, the years during which the home was open. I have been unable to get the exact numbers of infants in the home for the first three years separate from the remaining 22 years during which the system was in operation. The total number for the 25 years was 433—that is, an average of 17·35 per annum. For the whole of England and Wales in those years the deaths averaged 13·2 per cent. per annum from all causes, while in the home they were 7·8 per cent. The deaths in the home during the first three years amounted to 0·41 of the total for the whole 25 years, and were only included owing to the difficulty of separating the numbers in the records. Had they been omitted, the percentage for the 22 years during which the system was in operation would compare still more favourably with that for England and Wales. Also it must be borne in mind that the deaths from diarrhœa for the last 22 years were nil in the home, while the Registrar-General's figures work out at 2·25 per cent. for the whole of England and Wales.

If, then, it is possible, and I have shown it is possible, to apply the system to the everyday life of the nursery, two of the many great dangers to infant life will lose their terrors.

HEART-BLOCK:

A RECORD OF TWENTY CASES.*

BY J. STRICKLAND GOODALL, M.B., M.R.C.P., M.S.A. LOND., F.R.C.S., F.R.S. EDIN.,

LECTURER ON PHYSIOLOGY AT MIDDLESEX HOSPITAL MEDICAL SCHOOL; ASSISTANT PHYSICIAN TO THE NATIONAL HOSPITAL FOR DISEASES OF THE HEART; LATE CONSULTING CARDIOLOGIST, AUSTRALIAN AUXILIARY HOSPITALS.

FROM the year 1761, when Morgagni first described "Two Cases of Epilepsy with a Slow Pulse," which were in all probability examples of what was subsequently known as Adams-Stokes disease, interest has always centred round cases of heart-block, which are sufficiently uncommon to be interesting, while sufficiently common to be important. The writer therefore ventures to append an analysis of 20 cases of complete heart-block which have occurred within his practice during the past four years, in the hope that they may lead to a more complete appreciation of the condition.

The 20 cases were all carefully recorded. They included 15 males and 5 females, whose ages ranged between 4 and 74; the male cases ranging from 4 to 74 and the female cases from 27 to 65 years of age.

Family history.—Two of the cases were mother and son, and it is interesting to note in this connexion that both the grandmother and an uncle were said to have heart trouble with slow pulses. The Wassermann reaction was negative in both these cases. Another case was reputed to have had congenital heart trouble, and one brother and the grandmother were said to have had slow hearts. There were, however, none of the ordinary manifestations of congenital heart disease.

Personal history.—One man gave a history of rheumatic fever 40 years ago, one dated his trouble from an attack of "septic poisoning" followed by rheumatism, and one woman had a history of quinsy and tonsillitis. One man gave a history of syphilis 20 years before and had a definitely positive Wassermann reaction. Eleven of the cases gave negative Wassermanns. Six definitely attributed their condition to influenza. One case (a woman) gave a history of scarlet fever and one of diphtheria. Another case was obviously an acute myocarditis.

Symptoms.—The symptoms most commonly complained of were dyspnœa, "fits," pain, palpitation, vertigo. Fifteen of the cases complained of shortness of breath. Ten gave a history of definite fits (one having had them for over 19 years), while 10 complained of pain in the chest. "Palpitation" was complained of by 7 and appeared to be violent action of the heart due to extra-systoles. Four complained of vertigo.

Associated valve lesions.—Fourteen out of the 15 male cases had a systolic murmur at the apex conducted out to the axilla. One had, in addition, a presystolic murmur, and at times a diastolic murmur. In one case there was associated auricular fibrillation, and one case had apparently no valve lesion at all. As regards the five women, four had an apical systolic murmur conducted outwards, and one had a presystolic or diastolic murmur as well as a systolic.

It would appear, therefore, that 19 out of the 20 cases had mitral regurgitation, and 2 had mitral stenosis in addition.

The pulse.—The pulse-rate ranged from 10 to 64, and every case periodically exhibited an irregularity due to ventricular extra-systoles. The volume was full and the tension about normal.

Blood pressure.—This was usually well maintained, often slightly above the normal. A rise in blood pressure was frequently found to precede a fit. The lowest blood pressure recorded was 110 and the highest 180.

Work reaction.—Work reaction was good in most cases to low levels. The static test was also good.

Electrocardiographic examination.—Nineteen out of the 20 cases were electrocardiographed on several occasions, and all showed complete heart-block. Two of them, in addition, showed indications of a right branch lesion as well, seven showed a left-sided preponderance, and one showed a right-sided preponderance. Seven showed ventricular extra-systoles, and one case showed a very variable condition, at times complete heart-block, at others an obstruction to the right main branch, but with no obstruction to the main bundle. One case showed complete recovery. X ray examination showed typically large horizontal hearts.

After-histories.—Eight of these cases managed to carry on their ordinary light occupations, but had to take periodical rests. One man died suddenly at the house of a friend after a heavy meal. Post-mortem examination revealed the stomach very greatly distended and the heart displaced by pressure. One woman also died suddenly in a tram after a heavy supper; the stomach was found to be distended, the mitral valve stenosed and incompetent. This case had what was usually described as the third sound during life. A second woman died suddenly on the day following her mother's sudden death from heart disease. One woman became pregnant and was sterilised without mishap. One man had a prostatectomy successfully performed. This case subsequently died suddenly.

Summary and Conclusions.

The main points brought out by the above analysis appear to be: 1. The relative infrequency of a rheumatic or syphilitic history. 2. The almost invariable association of the condition with mitral regurgitation. 3. The tending to sudden death on gastric distension or exertion. 4. The occurrence of Stokes-Adams "fits" when the heart-block is complete. 5. The frequency of pain as a symptom. 6. The possibility of the condition being transmitted from mother to child. 7. The ability of some patients to work or even to stand severe operations.

CONGENITAL AND HEREDITARY DEFECTS IN RECRUITS:

OBSERVATIONS BASED ON THE MEDICAL EXAMINATION OF 25,500 MEN.

BY JOHN SINCLAIR MANSON, M.D. EDIN., D.P.H.,

MEDICAL OFFICER OF HEALTH, RUNCORN RURAL DISTRICT.

THE national necessity which has compelled the medical examination of large numbers of men of military age (18–41) has given an opportunity to observe in a short space of time the incidence of some diseases and defects having a relation to an hereditary or embryonic origin. Some of these are common to everyday experience; some are rare and exceptional even to the mature experience of men long in practice. When such rare cases appear in the small fraction of the population herein dealt with, it may not be too much to assume that, taking the population as a whole, these cases may form a class larger than has been supposed.

The analysis which has been here attempted is based on 27,794 examinations, of which 2294 were re-examinations, leaving a total of 25,500 men examined. The period covered is from Jan. 22nd, 1916, to June 15th, 1917. If a similar analysis were extended over all the men examined in the country, some idea would be given as to the range and limits of human variability as ascertained by external examination. No doubt the labour involved would be so great as to render it almost impracticable, but the results from the scientific point of view would justify it.

In making the examination of the foregoing cases none have been included where there has been a distinct history of trauma or acquired disease.

For example, all cases of epilepsy or mental defect where there has been a history of head injury have been excluded. The cases included comprise those idiopathic types which are generally acknowledged to have some more or less definite relation to heredity and those defects which are due to embryonic or intra-uterine causes. The cases have been grouped as follows:—

Central Nervous System.

1. Mental deficiency. This includes all grades from the merely dull and backward to the hopeless idiot with defects of speech and hearing, but it does not include cases of insanity or those with a history of insanity. Total number, 119. Proportion per 1000 examined, 4·7.

2. Epilepsy. All these cases have been confirmed either by medical certificates or by circumstantial evidence confirming the history. Only one case had an attack on the premises. Total number, 94. Proportion per 1000 examined, 3·6.

3. Doubtful epilepsy. History unconfirmed. Total number, 30. Proportion per 1000 examined, 1·2.

4. Deaf and dumb. Total number, 28. Proportion per 1000 examined, 1·1.

Eyeball.—Malformations of shape not apparent to observation are revealed by the cases of high myopia and high hypermetropia which occurred with some frequency. These are nearly always congenital or developmental. It was impossible to distinguish these from the lesser degrees of the same defects which were probably acquired and were very numerous. Conical cornea, total number, 3; congenital cataract, total number, 16. Double congenital coloboma in lower half of iris with eccentric pupil, 1. Captain R. Richards, R.A.M.C., reports "that the structures behind the iris are also involved and that both retinæ present coloboma of large extent. The case is of ophthalmological interest." Congenital coloboma in lower half of iris of right eye with eccentric pupil but with loss of left eye, 1. Double microphthalmus, 1. Congenital ptosis, 3. Colour blindness with family history of the affection, 1.

Pinna.—Small right malformed pinna with imperforate meatus, 1. Small left malformed pinna, meatus normal, 1. Right and left pinnæ pointed in the region of Darwin's tubercle, which was absent, 1.

Skin.—Psoriasis, total number, 60; per 1000, 2·4; ichthyosis, total number, 12; per 1000, 0·5; leucoderma marked, 1.

Goitre.—All cases of exophthalmic goitre excluded, owing to the frequency with which goitre appeared in the small number examined from the S.E. district of Cheshire. This group is divided into two: from Lancashire, 34; per 1000, 1·5; from Cheshire, 16; per 1000, 7·0.

Muscular system.—Absence of sternal portion of pectoralis major, 2 on right side, 2 on left—total number, 4. Congenital wry-neck, 3. Congenital dystrophy of muscles, 1.

Urogenital system.—Undescended testicle, 42; per 1000, 1·7. Extroversion of bladder, 2. Sexual immaturity: Miniature penis, scrotum, and testes with predominance of secondary female characters of feature, voice, and smooth hairless skin, 3. Pseudo-hermaphroditism: External genital organs presenting both male and female characteristics. The meatus opened behind a well-developed penis or clitoris with well-marked labia minoræ and majoræ. Small bodies, probably testes, could be felt in the inguinal canal and the individuals showed predominance of secondary male characters of feature, voice, and coarse hairy skin, 2. Mistaken sex—with complete female characters—genitalia, breasts, voice, and skin, dressed and working as a male from early life, 1.

Mouth and lips.—Cleft palate, 11. Hare-lip, 1.

Lower limbs.—Congenital dislocation of hip, 13; talipes valgus, 4; talipes equino-varus, 19; pes cavus, 17. In noting the last two groups the distinction between the congenital and the acquired varieties has not always been made; only 5 of the 19 cases of talipes equino-varus were noted as congenital. Webbed toes, 3; there were probably more cases of webbed toes which were noticed but not noted. Congenital stump of right leg below knee 4 inches long with three small buds representing toes, 1.

Upper limbs.—Congenital deformity of left scapula: The scapula was higher up and smaller than its fellow on the right. There was also some limitation of shoulder movements, 1. Congenital deformities of hand and forearm, 20. Only 11 of these can be specifically described, the other 9 are noted as congenital deformity of hand, but it is understood that this refers to either absence of one or more digits or to supernumerary digits with abnormal articulations and webbing. The following are the 11 cases: 1. Webbed third and fourth fingers on both hands. 2. Left hand with only thumb and little finger, absence of second, third, and fourth fingers—a condition of claw hand. 3. Absence of right thumb. 4. Supernumerary right thumb. 5. Macrodactyly—abnormally large middle finger, about twice the size of its adjoining fellows. 6. Both hands abnormally large, with family history of the condition. 7. Brachydactyly, with family history of the condition. 8. Congenital stump of left forearm, with two bony digits attached. 9. Congenital stump of left forearm 4 in. long, with five small buds representing digits. 10. Congenital stump of left forearm at the carpo-metacarpal articulation, with minature thumb and a row of four minute portions of nails representing digits. 11. Congenital deformity of right hand and foot. Right hand: Thumb normal in appearance; at base of right forefinger there is a marked constriction. A similar constriction is present round base of proximal phalanx of middle finger, which is much shortened. The ring and little fingers are abortive and fused together. Right foot: Much shortened owing to short metatarsals. The toes are represented by five imperfect diminutive digits.

Miscellaneous.—1. Hæmophilia, 3, with family history of the condition. 2. Albinism with nystagmus, 1. Two brothers and one sister affected, five brothers and one sister unaffected. 3. Blue sclerotics and brittle bones, 1. This person had markedly blue sclerotics and gave history of multiple fractures—left leg three times, right leg once, left arm once, and dislocation of both elbows. No family history in this case. 4. Left cervical rib, 1. 5. Spina bifida, lumbar region, 1. 6. Transposition of viscera, 1. 7. In coccygeal region, at base of coccyx a number of individuals showed a small rounded or oval swelling at upper part of the natal cleft. This swelling felt firm and fleshy, and when the natal cleft was wide, as it was in many of these cases, the appearance was very like that of an abortive tail.

Comments.

It need hardly be said that it would be unwise to generalise from the figures here given to the whole population. The number examined, 25,500, is too small a proportion, and, in addition, selections for the army from the age-group 18–41 had already been made during a period of 18 months previous to the commencement of these examinations. This selection would tend to concentrate the defectives, but even allowing for this the proportion of mentally defectives, epileptics excluding the doubtful cases, and deaf-mutes seems high. Aldren Turner[1] estimates the proportion of epileptics in this country to be about 1 per 1000. Kerr Love[2] estimates proportion of deaf-mutes for England to be 1 in 2043. For mentally defectives there are no statistics available for comparison. The discrepancy between former estimates and the present figures may be explained on the ground that the present system of examinations is bringing to light cases that would otherwise have remained obscure, together with concentration of defectives due to the continuance of the war.

A comparison between the congenital abnormalities of the upper and lower limbs seems worth noting from this study. The digits of the hand present a variety and complexity of abnormal structure not manifested by the digits of the foot, although both present normally a similar homologous structure. The congenital deformities in the lower limb are chiefly confined to the varieties of talipes and the defective formation of a socket for the head of the femur by the ilium, pubis, and ischium—congenital dislocation of hip. In the upper limb the scapula is homologous to the ilium, but in only one case did this present any congenital abnormality. It would seem that variations in the limbs chiefly take place along their line of function—the lower limb as a locomotory instrument, and the upper limb as a grasping instrument.

I am greatly indebted to my colleagues, Drs. E. E. Bowden, H. Langdale, W. J. Peacocke, and C. Robinson, for help, and to the president of the board, Major G. R. Fitzgerald, R.A.M.C., and also to the late Mr. Warren, the chief clerk, for assisting in a tedious enumeration.

Warrington.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

THREE CASES OF
TRAUMATIC RUPTURE OF THE SPLEEN.

BY C. M. PLUMPTRE, M.R.C.S., L.R.C.P. LOND.,
MAJOR, I.M.S.; SURGICAL SPECIALIST, 61ST I.S.H.

TRAUMATIC rupture of the spleen, unassociated with injury to any other abdominal viscus, is of sufficient interest to justify a brief account of three cases of this nature that occurred within a period of three months at this hospital. Two of the cases recovered satisfactorily after splenectomy; the third died two hours after operation. The patients, though Indians, were not the subjects of any marked chronic splenic enlargement, the organs on removal being about normal size and weighing respectively (1) 5 oz., (2) 7½ oz., (3) 8 oz.

The following are brief notes of the cases:—

CASE 1.—Cleaner, N.B. Railways. Admitted on 21/6/19 at 11 P.M. His history was that he had received a blow with the fist at about 7.30 P.M. the preceding evening. He had been sick and in pain during the day. On admission patient was very collapsed, pulse 130. His lips, tongue, and conjunctivæ were very pale. On palpation no absolute rigidity, but general resistance and pain most marked in left hypochondrium were present. There was abdominal dullness on percussion. Operation under chloroform and ether at 11.30 P.M. The abdomen was opened through the mid-line; the peritoneal cavity was full of blood and a large tear could be felt on the diaphragmatic surface of the spleen. The pedicle was controlled, the organ was freed and brought out of the wound and removed. As much blood as possible was mopped out of the abdomen, and 2 pints of saline with an ounce of ether poured into the peritoneal cavity. The abdominal incision was closed in layers. The patient was very ill for several days and had a sharp attack of bronchitis. Subsequently convalescence was most satisfactory, and when seen some five months later the patient was very fit and had increased considerably in weight.

CASE 2.—Driver, N.M. Machine Gun Company. Admitted 25/8/19 at 10.30 A.M. He said he had been kicked on the left side of his back the same morning about 6.40 by a mule. He complained of abdominal pain and had been sick once. He was not markedly anæmic, pulse 110. The left hypochondrium was rigid; there was dullness, which did not alter on turning the patient over, in the left flank, and general tenderness on abdominal palpation. Operation under chloroform and ether. The abdomen was opened through the left rectus and found to be full of blood. Two tears could be felt extending outwards from the hilum into the substance of the spleen, which was freed, brought out of the wound, and removed. The blood was mopped out of the abdomen and the wound closed. For four or five days there was an evening rise of temperature to 100°F.; convalescence was then uninterrupted, and the patient was evacuated apparently quite fit a month later.

CASE 3.—Driver P., Army Troops Transport. Admitted 10/9/19 at 10 A.M. He said that about 7 A.M. that morning he fell off a loaded A.T. cart which passed over his chest and stomach. Patient was very collapsed, sweating and markedly pallid, with a feeble pulse of 120. He complained of thirst, was restless and anxious. The abdomen was distended, painful on palpation, and did not move on respiration; both flanks were dull. Operation 11 A.M. under spinal anæsthesia. The abdominal cavity was opened through the mid-line, and was full of blood. A tear could be felt extending almost a third of the way through the organ on the diaphragmatic surface of the spleen, which was brought out of the wound and removed. The abdominal cavity was mopped free of blood, hot saline poured in, and the wound closed. Patient gradually got worse, and despite resuscitative measures became unconscious and died about two hours after the operation.

Observations on the Cases.

Case 1 was rather unusual, in that the injury had been sustained 24 hours before admission to hospital; it is possible that this was an instance of subcapsular bleeding with late rupture and intraperitoneal hæmorrhage. At the operation, a tear in the spleen, 2 inches long by 1 inch in depth was found.

All the patients exhibited the signs of severe intra-abdominal hæmorrhage, and operation was undertaken immediately in each case, saline being given during the operation. In two patients a mid-line incision was made; in the third the incision was made through the left rectus. It was found the spleen could be brought out sufficiently through either incision to ligature the pedicle without undue tension. No attempt was made to suture the spleen, the patient's condition and the damage to the organ, which in each case was very considerable, being taken to contra-indicate this line of treatment.

I wish to thank Lieutenant-Colonel M. Mackelvie, I.M.S., Officer Commanding the 61st Indian Stationary Hospital, for permission to report these cases, and Major P. Tarapore, I.M.S., and Lieutenant J. A. Ross, R.A.M.C., who very kindly acted as assistant and anæsthetist at the operations.

A CASE OF
CONGENITAL MALFORMATION OF THE LARGE INTESTINE
IN A NEW-BORN INFANT.

BY H. H. GELLERT, M.B., CH.B. EDIN.,
LATE SENIOR RESIDENT, METROPOLITAN HOSPITAL, E.

THE rarity of these cases justifies the publication of this one.

A full-term male child, born five days previously, was admitted to the wards of the Metropolitan Hospital on Feb. 13th with a slightly distended abdomen and a history of absolute constipation since birth. Delivered as a breech presentation, the child was cyanosed at birth. He appeared to be healthy and took feeds regularly by breast and bottle. Urine had been passed as well as flatus, but no melæna or fæces had been evacuated. No vomiting, restlessness, or evidence of pain noted.

On examination the child, a somewhat poorly developed infant weighing just over 5 lb., presented no evidence of discomfort or distress. Temperature 96·4°F., pulse 142, respirations 36. The abdomen was moderately and uniformly distended, and its appearance suggested distension of the small intestine. No peristaltic movements were visible or palpable, and no tumour was felt through the abdominal wall. Rectal examination at first gave the impression of atresia of lower part of rectum, but on more careful palpation it was obvious that the lumen of the bowel was patent, though very markedly narrowed. There were no evidences of developmental abnormality present elsewhere. Ol. ric. and a glycerine enema were administered without result, except for a small amount of slime. Feeds of milk and barley-water were taken. After observation for several hours no vomiting and no action of the bowels occurred and the abdomen became more distended, and laparotomy was performed.

Operation.—After a preliminary bandaging of limbs a small paramedian incision was made below the umbilicus and the peritoneal cavity was opened. Free gas and clear fluid exuded under pressure. Coils of motionless, congested, distended, and hypertrophied small intestine were brought into view. Small petechiæ were present over the surface of the gut and also areas of lividity. In addition small flakes of lymph and fibrinous serous exudate showed evidence of the onset of diffuse peritonitis. It was only with the utmost difficulty (and by enlarging the original incision) that a small contracted cord, no larger than a thick piece of string, representing the transverse colon, was brought into view. The distended ileum was ultimately traced to the ileo-cæcal junction, and a very much attenuated cæcum identified. Diligent search revealed no trace of any mechanical block by bands, volvulus, intussusception, &c. As the patient was showing evidences of cardiac embarrassment it became necessary to bring up into the parietal wound a loop of ileum close to the ileo-cæcal valve and open it on the surface. A small Paul's tube was inserted with a purse-string suture, and the abdominal wall closed in one layer. The condition of the child improved somewhat overnight. Hyd. cum cret. in half-grain doses was administered by mouth, but no action of the bowels resulted and no flatus was passed. Subcutaneous saline was transfused. The child died the following day within 24 hours of admission.

Post-mortem.—At the autopsy the stomach, duodenum, and coils of small intestine were all very markedly distended and the muscular coats hypertrophied. Ecchymoses and fibrinous deposits were present. Immediately adjacent to the ileo-cæcal valve, the ileum was collapsed, and showed a distinct perforation of the wall in the shape of a small ragged tear. The ileo-cæcal valve was patent. The large intestine was represented by a pale contracted band which would only admit a moderate-sized probe. From the diminutive cæcum downwards the colon was markedly attenuated and poorly developed in a gradual decline, especially marked below the hepatic flexure. A minute appendix was present. The small intestine contained liquid fæcal matter, and the contents of the ascending colon and cæcum consisted solely of bile-stained meconium. A thin plug of inspissated mucus was found blocking the lumen of the gut in the region of the splenic flexure. The large intestine was present in its entirety, and no atresia or occlusion (apart from the plug of mucus) was observed in any part of the colon. No other mechanical cause for obstruction was found. The condition of the large bowel was obviously due to malformation—microcolon—a developmental error in early fœtal life, and did not represent a state of collapse below an obstruction giving rise to mechanical ileus. No other developmental abnormalities were found post mortem.

I have to thank Dr. Edmund Cautley, under whose care the child was admitted, and Mr. Robert A. Ramsay, who operated, for permission to publish this case

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

EXHIBITION OF CLINICAL CASES.

A MEETING of this section of the Royal Society of Medicine was held on April 16th, Sir ANTHONY BOWLBY, the President, being in the chair, when clinical cases were exhibited.

Mr. ARTHUR EVANS showed a case of

Actinomycosis of the Thoracic Wall.

The patient first noticed pain and swelling in his left side and back about ten weeks before admission to hospital. He thought the present swelling was due to having been hit by a pole in the ribs. His previous health had been good. His occupation was an indoor one. There was on the left side a swelling of the lower thoracic margin, involving apparently the seventh, eighth, ninth, and tenth ribs and extending from the middle line to the mid-axillary line. The left thoracic margin, grasped between the fingers, felt three times as thick as that on the right. There was tenderness on pressure over the tumour. X ray examination showed the presence of a shadow in its region. An incision was made through almost its entire thickness, but no inflammatory focus was found. As the case was regarded as one of sarcoma the tumour was excised widely, which necessitated the removal of portions of the eighth, ninth, and tenth ribs, and the muscles of the abdominal wall adjoining. When this mass was removed the exploratory incision which had been made into the tumour substance was deepened, immediately subjacent was found a narrow streak of pus containing yellow granules, suggestive of actinomycosis. The base of the large wound was composed of peritoneum and pleura, both of which were unopened. As a substitute for the abdominal muscles two large silver filigrees were sutured into position between the peritoneum and the skin, covering an area extending from the outer border of the left rectus to the mid-axillary line, and from the rib margin to the level of the iliac crest. About three months after the operation a nodule appeared posterior to the site of the original tumour. This broke down and a sinus formed discharging actinomyces. The patient was put on large doses of potassium iodide, and the swelling gradually disappeared.

In answer to a question by Mr. A. W. SHEEN, Mr. EVANS said that there was no evidence to show how the infection gained entrance. At the operation he was able to shell off the peritoneum and pleura with ease, and there was no sign whatever that any tract had communicated with the tumour.

Mr. EVANS also showed a case of

Acute Osteo-myelitis of a Lumbar Vertebra.

The patient was a boy, aged 16½ years, who had left off work in October, 1919, feeling unwell. He had previously had three boils over the sacral region. Two days later he complained of headache and pain in the lower part of his back and in his legs; he began to have great difficulty in micturition and suffered from "pain in his stomach." There was no history of vomiting or of a sore-throat. When first seen in November he complained of great pain in his lumbar and sacral regions and in both legs. For ten days previously he had been running a temperature which had daily risen to 100°, 101°, or 102°. The cranial nerves were normal. Abdominal reflexes were present, the knee-jerks were absent, Achilles jerk was present, and the plantar reflexes gave an extensor response. He could flex and extend the right knee and ankle, but the movements were all feeble; he could flex but not extend the left knee and ankle. Both limbs were wasted, and especially the left quadriceps extensor cruris muscle. There was no sensory loss. There was evident tenderness over the upper part of the sacrum, more on the right than on the left side, and great tenderness on pressure over both erectores spinæ. A tentative diagnosis of acute anterior poliomyelitis involving the third and fourth lumbar segments was made. As the condition showed no improvement an operation was performed. A median incision was made over the lumbar spines and the muscles retracted. The third lumbar spine was found to be necrosed and loose, and from this site an abscess extended into the right and left erectores spinæ. On exposing the vertebral canal it was found to contain thick, yellow, odourless pus.

The canal was opened down to the sacrum Pressure over the latter caused pus to well up out of the superior aperture of the sacral canal, so this also was opened up along its entire length The whole of the exposed part of the spinal canal was filled with necrotic tissue covering over the dura and the cauda equina Bismuth iodoform paste was gently rubbed over it and the wound closed, save where it gave exit to a gauze drain For a few days after the operation there was incontinence of fæces Recovery was rapid, and in two months the patient could walk perfectly The cerebro spinal fluid obtained by lumbar puncture showed an excess of polymorphonuclear leucocytes, no organisms were seen

Mr **EVANS** also showed a case of

Cystic Adenoma of the Bile ducts.

It was that of a woman on whom he had operated in December, 1919 The patient was admitted to hospital in November She was emaciated, looked ill, was slightly jaundiced, and complained of constant pain in the upper part of the abdomen In the epigastrium and continuous with the edge of the liver was a tense cystic tumour reaching down almost to the umbilicus On opening the abdomen free fluid of a myxomatous nature was found in the peritoneal cavity The tumour proved to be a large cyst attached to the under surface of the liver On opening this yellowish viscid fluid escaped The examining finger felt masses of what were thought to be daughter cysts adherent to the inner wall They were detached with difficulty The greater portion of the cyst wall was removed, and a large drainage tube inserted Microscopical examination proved the tumour to be a multilocular cystic adenoma of the bile ducts

Mr **PHILIP TURNER** showed a case of

Fracture of the Left Humerus Non union (Pseudarthrosis) after 34 Years.

The patient, a man, aged 53 years, attended hospital about three weeks ago for partial rupture of the right biceps In the course of examination it was found that he had an ununited fracture of the left humerus, the result of an injury 34 years before, a report of which stated that he had been admitted to hospital in 1886 for injuries received as the result of a "stack of iron" falling on him There was a compound fracture of the right tibia and fibula, a fracture of the shaft of the left humerus about the junction of the middle and lower thirds, and a wound of the right hand with dorsal dislocation of all the first phalanges of the fingers The fracture of the humerus was treated at first by an anterior angular splint with three small splints, later by a plaster of Paris splint, and then, as this was not satisfactory, by an internal angular splint and small splints Before discharge it was noted in the old hospital reports "Position better, much firmer union" Though at present there was a very marked deformity, the appearance superficially resembling a Charcot's disease of the elbow joint, the functional result was remarkably good The elbow joint was not absolutely ankylosed, but flexion and extension of the forearm on the arm took place in the false joint, where, in addition to the normal movements, there were also lateral mobility and a certain amount of hyper extension The muscles of the forearm and arm were well developed and there was a powerful grip All the normal movements of the arm and forearm could be carried out with the exception that, owing to lack of rigidity in the false joint, the arm could not be raised above the level of the head The patient said that the arm was "strong, but not quite so strong as the other" He had continued since the accident in his original employment as a labourer at an ironworks, the work was very heavy and included lifting heavy girders There was no pain in the joint and the patient complained of no disability The case was shown on account of the very long interval since the original injury, and to demonstrate that a strong, useful and painless arm might result with an ununited fracture of the humerus

Tuberculous Caries of Mid dorsal Spine

Mr **A W. SHEEN** showed a girl aged 22, who had been admitted to hospital with rather acute tuberculous caries of the mid dorsal spine There were pain and tenderness and the patient had become very thin. A tibial bone graft was inserted in 1914 She remained in hospital for three months after the operation and rested at home for six months, had a holiday, and then resumed work. She could get about satisfactorily and do her work. According to a recent X ray report there was considerable bowing, but no caries, while the graft showed like a long curved rod and was rounded off

The **PRESIDENT** remarked on the slight degree of deformity which was present, and which was not of the angular type

HUNTERIAN SOCIETY.

TREATMENT OF ANTE NATAL AND POST NATAL SYPHILIS.

A MEETING of this society was held on April 14th at the Venereal Diseases Centre for Pregnant Women, 18, Thavies Inn, Holborn Circus, E C , at the invitation of Mr. John Adams, Dr. W. **LANGDON BROWN**, the President, in the chair The society had already marked its appreciation of the pioneer work done by Mr Adams at this centre by awarding him its medal, which is awarded annually with the object of encouraging individual effort among general practitioners in advancing the science and art of medicine

Mr **ADAMS** said that the centre was established in 1917 for the treatment of syphilitic pregnant women and their babies, and the results might be judged by reference to the following table —

Year	Syphilitic mothers	Babies with positive W R	Babies with negative W R	Stillborn
1917-18	23	17*	6	5
1918-19	30	8†	21	1

* 3 died—1 aged 6 hours 1 aged 14 days, 1 aged 36 days
† 1 died aged 2 months

The cases undergoing treatment at the centre were first shown—nine mothers with babies of various ages up to 2½ years being demonstrated, and their healthy appearance gave some indication of the success of the treatment adopted Mr Adams said that the results obtained since the centre was first opened had been sufficiently striking to warrant certain definite conclusions[1] being drawn from them A syphilitic pregnant woman could be treated safely and effectively with arsenical preparations up to the day of her confinement Such a woman, if actively treated, might give birth to a child with a negative Wassermann, although her own blood might still be positive. The child throve if the mother had been treated. If, however, the child was syphilitic when born it could be treated immediately after birth with safety and considerable benefit These beneficial results were obtained by intramuscular injections of galyl dissolved in glucose solution, but were considerably enhanced by simultaneous intramuscular injections of mercury, combined with oral administration of hyd cum cret Further, the child was found to respond much more readily than the mother to treatment if one judged by the blood test The child throve, put on weight, and became quite normal The fact that no syphilitic manifestations had been observed in any of the babies born during the past year and actively treated at this centre illustrated very forcibly the effects of treatment.

Demonstration of Methods of Treatment

The demonstration of the methods of treatment employed at the centre took place in the theatre Mr Adams showed syphilitic infants undergoing treatment by intramuscular injections of galyl in glucose solution and mercury (grey oil). The initial dose of galyl used is 1 5 cgm , and is given on the day of birth followed by a similar dose after a week. From then onwards the injections are given fortnightly and the results of treatment controlled by the application of the Wassermann test at intervals In Mr Adams's view it is important to give the galyl in glucose solutions, and the doses gradually increase from the initial dose of 1 5 cgm. to 5 cgm. The combined mercurial treatment commences after the first week and is given in the form of intra muscular injections of grey oil into the buttock For this purpose a special syringe has been devised, provided with 15 divisions, each division corresponding to one fortieth of a cubic centimetre When 40 per cent grey oil is used, each division then contains 1 cgm of mercury. The grey oil used for the babies is 20 per cent., and the amount given is raised gradually from ¼ gr. of mercury to ½ gr. It is conveniently injected into one buttock, and the galyl injected into the other, both injections being administered fortnightly. The maternal injections are given weekly. At the demonstration, the blood for the Wassermann test was taken with ease and rapidity from the heel of the infants. The foot had been placed in hot water for a few minutes, and then dried, and held in the left hand, while three stabs with a needle quite close together were made into the heel. Blood flowed freely, and the flow was assisted by gentle squeezing. The actual treatment of the syphilitic mother was also shown.

---

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this society on April 1st a discussion was held on

Anæsthetics.

Mr. **HERBERT HALLAM**, in opening the discussion, after comparing the merits of ether and chloroform, said that the only two safeguards against overdose were a knowledge of the physiological action of chloroform and the maintenance of a free airway. He then enunciated his theory of the cause of chloroform overdose as follows. Air containing chloroform enters the lung alveoli and the vapour is absorbed by the blood, such absorption depending on (1) the percentage of chloroform in the inhaled air; (2) the air pressure in the alveoli. Thus a to-and-fro current of air containing chloroform goes on in and out of the lung alveoli, and as more vapour is absorbed the characteristic signs of anæsthesia develop. So far only the tidal air in the alveoli is involved. If this exchange occurs with freedom all is well, but if any interference with respiration occurs through obstruction the situation is altered to one of extreme danger. The remedy for obstruction is expiratory effort, and the combination of effort and obstruction raises the alveolar pressure, with involvement of the residual air and rapid absorption of chloroform leading to an overdose. The patient is poisoned, not from the chloroform on the mask, but from that in his alveoli. Illustrations in support of this theory were: (1) In the operation for tonsils and adenoids a patient lightly under may through obstruction from the tongue or the manipulations of the surgeon become suddenly poisoned; (2) the absence of poisoning where intratracheal chloroform by means of a catheter is employed with its free airway; (3) the rapid recovery from poisoning when, by removing obstruction and performing artificial respiration, intra-alveolar pressure is removed. Lastly, he referred to the question of idiosyncrasy to chloroform and the value of suggestion before operation.

Mr. W. T. **DAKIN MART** then demonstrated Boyle's Gas and Oxygen Apparatus. He pointed out that at the outset it was essential to see that all adjustments were in order and that sufficient gas and oxygen was at hand, and that the reserve cylinders were ready for immediate switching on; to turn the taps on gradually and see that the lamps attached to the neck of the cylinder were burning in order to prevent freezing; to make sure that the face-piece was firmly attached to the patient's face in order to give the anæsthetist absolute control over the mixture. So far as circumstances allowed the patient should be comfortably placed with the head slightly raised. The anæsthetic should be given in the theatre and absolute quiet was essential. No holding of the patient was desirable or necessary. He advocated preliminary medication with morphia ¼ gr. and atropine 1/150 gr. 20 minutes before the start of the operation. In abdominal operations the abdominal wall should be anæsthetised, after the patient is under, by means of ½ per cent. novocaine and ¼ per cent. potassium sulphate given independently and injected layer by layer. This prevented pain after coming round, and so enabled the patient to breathe more deeply and clear the lungs more quickly. It was desirable to start the induction with a pressure equal to one hole of oxygen and three of nitrous oxide. The patient first breathes air until the bag is three-quarters full of the above mixture, when the valves are turned on and he breathes from the bag and into the air. Then re-breathing in and out of the bag is commenced. The colour of the ears should be watched, and if they become dusky more oxygen should be given. The signs of complete anæsthesia were regular quiet breathing, sometimes difficult to obtain when there was much re-breathing, pupils small and active, eyes moving, and a normal pink colour. The signs of deep anæsthesia were snoring, which was difficult to avoid with the re-breathing mechanism, dusky tinge, jactitation, rolling up of the eyeballs, and dilatation of the pupils. These signs indicated that more oxygen should be given. Suitable cases for this method were amputations, chest cases, cases suffering from severe shock, and pneumonia and bronchitis requiring operation. Nose and throat cases were difficult to anæsthetise by this method. Advantages over other methods were: no fall of blood pressure, very little vomiting, rapid recovery from the anæsthetic, and often an improved general condition of the patient after the operation.

Mr. R. V. **FAVELL** demonstrated Marshall's apparatus for gas and oxygen, and many other members took part in the discussion, including Dr. T. Robertson, Dr. R. J. Hillier, Dr. W. Sneddon, Dr. N. Milner, Dr. J. B. H. Holroyd, Dr. T. B. Stedman, and the President.

BRISTOL MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A CLINICAL meeting of this society was held at the University of Bristol on April 14th.—Dr. D. A. **ALEXANDER** showed a case of Myxœdema; also a case of Tetany in a boy of 18, with defective physical development and a rather full thyroid gland.—Dr. J. M. **FORTESCUE-BRICKDALE** showed a boy of 19 with very defective development, probably due to pancreatic insufficiency.—Dr. J. R. **CHARLES** showed a case of Myelogenous Leukæmia, with symptoms indicative of a lesion of the labyrinth on both sides, coming on simultaneously and acutely.—Mr. **HUBERT CHITTY** showed a child with an Inclusion Dermoid of the Scalp; and another patient with a Lymphangioma of the Cheek, under treatment by electrolysis through the mucous membrane.—Dr. **RICHARD CLARKE** demonstrated a specimen of Pituitary Tumour; the chief symptoms had been acromegaly, optic neuritis, and diminished glucose tolerance.—Mr. J. P. I. **HARTY** and Dr. F. J. A. **MAYES** showed a case of Epithelioma of Tonsil, Palate, &c., undergoing treatment by diathermy and injections of copper alanin, with promising results.—Mr. **CLIFFORD MOORE** showed a boy with Schlatter's Disease (bilateral).—Dr. J. A. **NIXON** showed a child with Morbus Cordis and Congenital Syphilis; a man with Steatorrhœa following Gastro-enterostomy (possibly due to implication of the pancreas in the base of a gastric ulcer); and a youth convalescent from an illness resembling to some extent Toxic Polyneuritis and also Encephalitis Lethargica.—Dr. **GEORGE PARKER** brought a number of children with Infantile Diplegia, to whom thyroid extract was being given with benefit; also cases illustrating Paralysis of the Serratus Magnus and of the Trapezius; and a man with a lesion of the external cutaneous and genito-crural nerves associated with an operation for inguinal hernia.—Mr. A. **RENDLE SHORT** showed two patients doing well after Albee's operation for tuberculosis of the spine; and a specimen of Malignant Papilloma of the Renal Pelvis removed by Operation.—Dr. J. O. **SYMES** showed two patients exhibiting an Indurative Erythema of the Skin over the calves of the legs.—Dr. P. **WATSON-WILLIAMS** showed a patient from whom he had removed a large Polypus of the Sphenoidal Sinus, together with the tumour.—Dr. **CECIL WILLIAMS** showed a case of Œdema of both Eyelids in a boy whose mother had been similarly affected after eating oranges; there was reason to regard the boy's lesion as the outcome of a similar "toxic idiopathy."—Mr. C. **FERRIER WALTERS** showed two patients with Exophthalmic Goitre who had been relieved by the Dunhill operation.—Dr. W. **KENNETH WILLS** showed patients cured, by a single dose of X rays, of (1) Rodent Ulcer of three years' standing, (2) Lupus Erythematosus Discoides; also a man with a Syphilitic Tumour of the Maxilla undergoing successful treatment with novarsenobenzol; and a severe and intractable case of Dermatitis Herpetiformis.—Mr. **DUNCAN WOOD** showed four ex-Service patients in whom persistent traumatic bony defects had been closed by grafts of living tissue-muscle in three cases and bone in one.—Mr. A. J. M. **WRIGHT** showed a man with Cicatricial Stenosis of the Larynx due to a gunshot wound, in whom laryngostomy had been performed, and would be followed later by a plastic operation for closure of a cartilaginous graft.

A CONJOINT meeting of the Obstetrical and Gynæcological Section of the Royal Society of Medicine with the North of England and Midland Obstetrical and Gynæcological Societies will be held in London at the rooms of the Royal Society of Medicine, 1, Wimpole-street, W., on Thursday, May 6th. The discussion at the morning session will be on the Treatment of Ante-partum Hæmorrhage, opened by Dr. Hastings Tweedy at 10.30 A.M. At the afternoon session a discussion on Rupture of the Cæsarean Section Scar in Subsequent Pregnancy or Labour will be opened by Dr. Eardley Holland, and followed by statistics from various hospitals throughout the country. A dinner will be held at 7.30 P.M., at the Great Central Hotel, Mr. J. D. Malcolm, President of the Section, in the chair.

Reviews and Notices of Books.

A TEXT BOOK OF GYNÆCOLOGICAL SURGERY

Second edition By COMYNS BERKELEY, M A , M C , M D Cantab , F R C P , Gynæcological and Obstetric Surgeon to the Middlesex Hospital, &c , and VICTOR BONNEY, M S , M D , B Sc Lond , F R C S , M R C P Lond , Assistant Gynæcological and Obstetric Surgeon to the Middlesex Hospital, &c London Cassell and Co 1920 With 489 figures in the text and 16 colour plates Pp 829 42*s*

THE first edition of this work appeared in 1911, and in consequence of the time that has elapsed numerous alterations have been necessary. A considerable amount of space is devoted to the authors views on the ætiology of prolapse of the uterus and vagina Not many gynæcologists will be found to agree with their suggestion that the broad ligaments play an important part in the suspension of the uterus in its normal anteverted position They describe an upper, a middle, and a lower segment of the suspensory apparatus, and from this deduce that there are seven clinical varieties of displacement of the genital canal, the operative treatment of each of which they discuss in detail We are glad to see that they strongly deprecate the operation of hysterectomy for any of these conditions , they point out the true use of shortening of the round ligaments, and do not recommend this operation for procidentia uteri

In the section on the preparation of the abdomen before operation they advocate the use of crystal violet and brilliant green, and bring forward evidence to show that this antiseptic is more certain than iodine as ordinarily used We cannot agree with the authors that abdominal drainage is better than vaginal, and we believe that the discharge is freer and continues longer from the upper opening because the drainage is less efficient and the track more extensive The description of the operations necessary for the removal of cervical myomata is good, and should prove helpful to the young operator The section on extended abdominal hysterectomy is very good and full , it is a pity that the authors have not brought their results up to date, as their experience is a large one, and a good deal of doubt is arising in the minds of many gynæcologists as to the ultimate value of this operation There are those who believe that the time is coming when it will be displaced altogether by the use of radium

The operation of myomectomy is one that appeals very much to the authors We are not sure that their arguments are convincing, and fancy that most surgeons will still regard myomectomy as an incomplete operation only suitable for a limited number of cases, and that when the uterus is the seat of multiple fibroids it is better removed Section of the uterus is suggested too often, in our opinion, in this book We regard utriculoplasty as an unnecessary and dangerous operation which will not survive, and we cannot agree that hysterotomy is ever indicated or proper as a preliminary to scraping the endometrium or for the purpose of removing a mucous polypus The recommendation of Cæsarean section for the great majority of cases of placenta prævia would, if carried out in any number of cases, most certainly increase the death rate to the mothers without increasing the number of children which would survive (It must be remembered that the risk to the child is due to a number of factors, that the results of Cæsarean section in cases of premature children are most discouraging, and only some 30 per cent of all cases of placenta prævia go to full term The recommendation to evacuate the uterus in cases of tuberculosis and then to sterilise the patient by tying the tubes is opposed to the most recent observations on this subject, which show that the safety of the patient is best assured when the uterus is removed intact by hysterectomy and not emptied first

There is much of extreme interest in this book, the operations are clearly described, and the diagrams are very good The positions taken up are not, in our opinion, as we have indicated, always unassailable, but the authors' views are founded on great practical experience The book will be chiefly useful to the expert who is in a position to discount the partiality for obstetric surgery as opposed to obstetric medicine The coloured illustrations are well reproduced and the index is a good one

MEDIÆVAL MEDICINE

By JAMES J WALSH M D London A and C Black, Ltd 1920 Pp 216 7*s* 6*d*

Dr Walsh s books on mediæval medicine are always interesting, but when we read them we are reminded of a remark by a character in Conan Doyle's "Rodney Stone ' concerning the relative merits of pugilists of different nationalities 'When you get a good Irishman you can t better 'em, but they're dreadful asty " For Dr Walsh, though a learned man and an enthusiast in mediæval medicine is prone to make unfounded statements We were impelled to point out this trait when we reviewed his work on the "Thirteenth Century, [1] and the same hastiness is obvious in the book now before us Quite early in the book (p 7) we find the following statement —

> Among them are particularly to be noted certain members of an Arabian family with the title Bachtishua a name which is derived from the Arabic words *Bocht Jesu*—that is servant of Jesus—who having studied among the Greek Christians in Asia Minor were called to the court of Haroun al Rashid and introduced Greek medicine to the Mohammedans

Now the Bachtishuas were not Arabs, but Syrians and they did not study among Greek Christians in Asia Minor, but among Nestorian Christians at Gondisapor, in Persia, although it is true that their medicine was Greek On p 12 Dr Walsh refers to the commonly received opinion that Aristotle dominated mediæval thought with the implication that this opinion is wrong On p 13 he mentions that in another work he had given quotations from Albertus Magnus and Roger Bacon to prove that mediæval scientists did not go by authority but by experiment and observation , and finally, on p 16, he refers to the fact (that Roger Bacon wanted the Pope to forbid the study of Aristotle And why ? Because, to quote Dr Walsh's own words—

> His works were leading men astray from the true study of science—his authority being looked upon as so great that men did not think for themselves but accepted his assertions

No one denies the greatness of Aristotle's intellect, but the obsession of his authority undoubtedly did do harm to the study of natural philosophy For instance, until Galileo showed that Aristotle was wrong everyone believed that if a 10 lb weight and a 1 lb weight (supposing them to be the same shape) were dropped from a height, the 10 lb weight would strike the earth first, because Aristotle had said that it would and even when Galileo made his well known experiment from the Leaning Tower of Pisa, and showed that the two weights struck the ground simultaneously, many people still maintained that Aristotle was right and that Galileo must have made a mistake

The most blatant of Dr Walsh s hasty statements is the following (p 174) He is talking about the number of hospitals which were founded in Europe at the instance of Innocent III , and undoubtedly there were many But in his zeal for his favourite century and Pope he says —

> The traditions with regard to France are quite as complete as those that concern Germany and the great hospitals of London—St Thomas s St Bartholomew s which had been a priory with a house for the care of the poor but was now turned into a hospital Bethlehem afterward Bedlam Bridewell and Christ s Hospital the first of which afterwards became a prison while Christ s Hospital though retaining its name became a school The Five Royal Hospitals as they were called were either founded or received a great stimulus and thorough reorganization during the thirteenth century

Again, on p 200 Dr Walsh says —

> Bedlam in England which had been the old Royal Bethlehem Hospital for the care of all forms of illness came to be just before the end of the thirteenth century exclusively for the care of the insane

Now, let us see the facts St Thomas s Hospital was certainly founded in 1228 by Peter de Rupibus So far Dr. Walsh is correct. St. Bartholomew's Hospital was founded in 1123, together with a priory; the hospital came first, the priory second. There was no turning into a hospital in the thirteenth century; neither is there any evidence of great stimulation or thorough organisation during that century. Bethlehem Hospital —i.e., the Hospital of St. Mary of Bethlehem without Bishopsgate—was founded as a priory in 1247, and is not called "hospital" before 1329, while the earliest record of lunatics being cared for there is 1377. The Royal Commission of 1403 mentions six lunatics as being in the hospital under restraint. This Commission, we expect, is that to which Dr. Walsh refers on p. 188 when he says:—

---

[1] THE LANCET, MAY 9th 1908

> "There is definite evidence of Bethlehem in London, afterwards known as Bedlam, containing lunatics during the thirteenth century, for there is the report of a Royal Commission in the next century stating that there were six lunatics there who were under duress."

But he seems to consider that the thirteenth century includes all years beginning with the number 13—or in the case of Bridewell extending to years beginning 15—for Bridewell did not exist until 1522, when it was built in the lordly Tudor way by Henry VIII. for the reception of the Emperor Charles V. Edward VI. gave it to the city on the appeal of Ridley, Bishop of London, as a workhouse for the poor and a house of correction for "the strumpet and idle person." Christ's Hospital did not "retain its name" on becoming a school, but was given it then—i.e., in 1555—the school being housed in what was left of the old Grey Friars Monastery, which was despoiled by Henry VIII. The monastery had been founded in the thirteenth century, but the foundation had nothing to do with the school.

On p. 207 we find another hasty statement; Dr. Walsh quotes a decree of the Emperor Frederick the Second as to the practice of medicine in the Kingdom of Sicily, which states that "no one be permitted to take up the study of medical science without beforehand having devoted at least three years to the study of logic." Dr. Walsh then says in a footnote—

> "Under logic at this time was included the study of practically all the subjects that are now included under the term the seven liberal arts."

We should much like to know his authority for this statement, especially as "this time" is 1231.

As for the rest of the book, there are some interesting illustrations and pleasant chat about Salerno and some of the mediæval surgeons, such as Lanfranc and Mondeville, but we cannot regard the work as a serious contribution to the study of mediæval medical history.

TUBERCULOSIS AND PUBLIC HEALTH.

By H. HYSLOP THOMSON, M.D., D.P.H. London: Longmans, Green, and Co. 1920. Pp. 104. 5s.

Dr. Hyslop Thomson is a bold author, who has [illegible] to provide a short and concise study of [illegible] in relation to public health of interest to medical and non-medical readers. The book is [illegible]ly short and up to a certain point concise. It is full of information which will, no doubt, in the author's words, "assist in removing some of the popular misconceptions which exist with regard to various aspects of this disease." To the medical profession in general, and to the tuberculosis specialist in particular, this book will seem sketchy and incomplete, though here and there the author gives first-hand information of real value. Approaching the subject as he does from the point of view of the medical officer of health, his survey is necessarily wider than that of the tuberculosis specialist who is apt to study the disease as such, rather than the complex fundamental factors of which tuberculosis is a late by-product. Referring to the problem of housing, the author asks why, if it is possible to build houses calculated to maintain the health of the individual with arrested tuberculosis, such houses are not erected on an extensive scale so as to prevent the development and spread of the disease in the healthy population? We repeat this question.

The author does not consider tuberculosis as a highly infectious disease, and he maintains that if certain precautions are taken, the risk of infection from contact with open cases of tuberculosis becomes very slight indeed. This belief of his may be contrasted with his statement that the "segregation in suitable institutions of advanced cases of open pulmonary and non-pulmonary tuberculosis is a measure which has far too long been delayed, and is the one which should constitute the foundation of every scheme of treatment."

RULES FOR RECOVERY FROM TUBERCULOSIS.

Third edition, thoroughly revised. By LAWRASON BROWN, M.D. Philadelphia and New York: Lea and Febiger. 1919. Pp. 192. 15s.

IT is given to few authors to write a book for the lay public so full of important matter, well digested, that medical practitioners and even specialists in tuberculosis may read it with great profit to themselves. In the present edition some details have been added as to the values of foodstuffs, and a liquid diet has been outlined with special reference to patients with failing appetite. Many other changes have been made here and there to keep the book abreast of the times. But these changes concern details rather than principles, and the absence of marked changes in the present edition is a tacit tribute to the soundness of the teachings of the previous edition. As the author generously admits, much of this book represents the expressions, similes, ideas, and teachings of the pioneer in the art of imparting advice to tuberculous patients—the late Dr. Trudeau.

In fact this book represents the life experience of a patient who turned disaster into victory, as well as the views of one of America's greatest living authorities on tuberculosis. The author is cheery and optimistic throughout, but he is also careful to convince the reader that tuberculosis takes years to cure. In this connexion he points out that 38 per cent. of all the patients treated at the Trudeau Sanatorium have died, although in many of these cases death was not inevitable; had but the patients practised common-sense they would still have been alive. With regard to alcohol the author accuses private sanatoriums in Europe of prescribing alcohol more freely than similar institutions elsewhere. He has nothing good to say of alcohol, and he notes that since the death of Dr. Austin Flint, no great student of tuberculosis in America has advocated its use. Many a sanatorium physician will find parallels to the case of the conscientious but unintelligent patient who, being told to walk only 10 minutes a day, saved up his exercise for a week and then took a 60-minute walk. The recent violent swing of the pendulum against tuberculin is not reflected in the author's estimate of this remedy. He does not claim to understand its action fully, but he notes that it achieves remarkable results in a few cases. Another small group of cases cannot tolerate it, but the vast majority take it well, although they experience, apparently, little benefit from its use. The author's choice of text wherewith to head each chapter is usually apt, but when he heads his chapter on the care of the mouth with: "Out of thine own mouth will I judge thee," his exercise of the poetic licence seems a little free.

SANITATION AND HEALTH IN INDIA.

A MANUAL OF CONSERVANCY. By JAHAR LAL DAS, L.M.S. Cal. Univ. London, India, Winnipeg, and Sydney: Butterworth and Co. 1919. Pp. 190. Rs. 5.10.

PERSONAL HYGIENE. By M. R. SAMEY, M.D., D.P.H., M.O.H. Same Publishers. 1920. Pp. 96. Rs. 3.

BOTH these books are written with special reference to India and with the praiseworthy objects of promoting respectively the sanitation of the country and the hygiene of the person. Mr. Jahar Lal Das, who is health officer to the district board of Burdwan, deals with the removal and disposal of refuse of all descriptions, the management of cattle employed on conservancy work, and the prevention of disease among them. Illustrations of the various kinds of apparatus necessary for carrying out the work are used freely to elucidate the text, and an appendix sets out Indian local sanitary laws. There is also a chapter on ankylostomiasis from the point of view of its intimate relation with the pollution of the soil. Professor Charles A Bentley, the Sanitary Commissioner for Bengal, who writes an introduction to the book, points out that the sanitary reformer in India is often discouraged by the ignorance and apathy of the population and by the defective sanitary organisation This little manual, while helping the sanitary inspector, should also assist in educating the more intelligent classes with regard to some of those things on which the health of the *community depends*

Dr. Samey's book keeps in mind the social, economic, and religious conditions which to some extent tend to modify the rules of health suitable to an English-*speaking community, though, generally speaking,* the laws which govern healthy living are the same for all peoples. Foods may differ, but the need for fresh air and cleanliness is everywhere the same. The chapter on Regulating the Passions is somewhat novel for a book of this kind, though quite relevant, here it is pointed out that emotion will arrest, alter, or modify the various organic secretions, the only guarantee for a long life of health and happiness being a constantly cherished even, cheerful, and hopeful spirit Dr. Samey has compiled a useful little manual

MARINE HYGIENE AND SANITATION

A Manual for Ships' Surgeons and Port Health *Officers By* GILBERT E BROOKE, *M A Cantab*, L R C P Edin, D P.H, F R G S. London Baillière, Tindall, and Cox. 1920 With 4 plates and 27 figures in the text Pp x + 409 15*s*. net

THIS book breaks new ground Others have told the ship's surgeon what to do on board his ship and have mentioned his relations with *the* sanitary authorities of the ports he visits, but this book tells him what the sanitary authorities want, why they want it, how he can help them most effectively, what returns he should have ready for them, and how therefore he can most quickly and certainly secure *for* his ship the shortest period of the expensive and unpopular delay "at quarantine" The ship's surgeon who knows this book and acts up to its advice will earn golden opinions *from* his captain, and may even get a bonus from his company if its directors are wise The ship's surgeon is here taught to be methodical in the preparation of such information as is required by the visiting medical officer

The book is well written and well illustrated, though there might have been a plate of stegomyia and other mosquitoes Its accounts of the "origines" of naval hygiene are interesting always; but has the author ever heard of Lind, who is unmentioned in relation to scurvy, and is he the "Lynn" of p 82, who invented the *distillation of* water *on board* ship? The author, who is port health officer at Singapore, has also a good book on tropical disease to his credit. He has visited and made sanitary examinations of many ships, and from his experience easily convinces us *of* the loss British ships suffer both in hygiene and comfort for want of a sanitarian *to give approval* to their design. It is only when the ship is built and in service that a sanitary inspection is held, and the defects then found are often so bewildering that they cannot all be put right The building of standard ships by Government during the war *raised* the level of crew accommodation, the unions also are getting interested and taking action, and though the Ministry of Health has not yet taken a hand in the matter the hygiene of crew spaces is improving. Dr. Brooke's form on which to enter up the sanitary survey of each ship is well thought out. It is satisfactory to find that he constantly quotes with approval the Admiralty Transport Regulations, under which so many soldiers have been taken about the world in this war. As regards beri beri, Dr. Brooke, living in the midst of *beri beri and polished rice*, is *of opinion* that beri beri is due to a micro-organism, present in hot and moist air, finding in polished rice its favourite soil, with an antagonist in the pericarp *of* the rice grain, an opinion heretical just now, but yet with reasons behind it, as every reader will see

The author's first aim is to prevent cases of dangerous disease from eluding his observation, secondly, in every way to avoid unnecessary detention of ships which would hamper trade The modern practice, for which he pleads, is to disinfect a ship at the infected port of departure, that it may be unnecessary to *do* so at the port of arrival Dr Brooke *foreshadows* a time when appointments as port health officers will by statute be given only to men who have served at sea, have a thorough knowledge of tropical diseases, and have specialised in port work

THE LOCAL WAR PENSIONS COMMITTEES' HANDBOOK.

THIS handbook, which consolidates the circulars and instructions issued by the Ministry of Pensions, *other than* those concerning the functions of the Special Grants Committee, has now been placed on sale (price 2*s*) by H M Stationery Office. Arranged in five parts, corresponding with the main divisions of the work of the local committees, it replaces the Instructions for the Assessment of Alternative Pensions, 1917, Instructions and Notes on the Treatment and Training of Disabled Men, 1917, Instructions on the Treatment of Disabled Men, 1918, and Ministry of Pensions Circulars issued *prior to Jan. 1st, 1920 The handbook itself* affords a comprehensive and detailed summary of information which will be valuable to all interested in the administration of pensions and the after care of the disabled, while among the Appendices will be found the complete text of the Royal Warrant of Dec 6th, 1919, under which soldiers' pensions are awarded

JOURNALS.

Tubercle A Monthly Journal Devoted to All Aspects of Tuberculosis. Vol. I, No. 7 April, 1920—The piece de résistance in the April number is an article by Professor C. Saugman on Extrapleural Thoracoplasty, in which he traces in *considerable detail* its history, technique, and results. The indications are practically those for artificial pneumothorax, and in every case this should be tried first. The operation should also give place to Jacobœus's cauterisation of adhesions or to local plastic methods or excision after removal of small pieces of rib, when these milder procedures are possible. Thoracoplasty is recommended in chronic fibrosis, especially with basal cavitation, apical cavities being more difficult to compress and sometimes requiring removal of the upper ribs in front besides the posterior resection. Based on Friedrich's *operation* (1907), the method now advocated by Professor Saugman has been so mitigated as to be relatively safe *Local* anæsthesia is used, except when intolerance to novocaine suprarenin has *been found at* the attempted artificial pneumothorax, and the operation *is divided into* two stages separated by an interval *of a few* weeks *At* the first stage ribs 11 to 5 are attacked, and at the second stage ribs 4 to 1. It is important to remove part, if only a small part, of the first rib. The article is well illustrated and is *documented with a synopsis of the 40 cases treated* from 1916 to 1919 Of ultimate results it is yet early to speak, but the fact that 13 patients are already at work speaks well for the future treatment of some desperate cases An *abstract of an article* by Dr. P. Bull, *of* Christiania, gives his experiences of practically the same operation, and he reckons on getting a "*curative* result" in about one third of the cases—A series of abstracts on tuberculous adenitis raises the difficult question whether this affection confers any immunity to pulmonary tuberculosis, but the answer remains doubtful Dr. W. R. Abbott, of Springfield, Ill., lays down useful guiding principles *for* the treatment of cervical adenitis First, correct any error in the area from which lymph drains to the affected glands—e g., teeth, tonsils, ears. Next, operate early if enlargement, softening, or tenderness of the glands is present, but do not operate when glands have broken down and the disease has extended deeply. In some of these cases aspiration with injection of cinnamon and benzoin is recommended. Thirdly, the author is strongly persuaded of the value of tuberculin above all other remedies, and the drug is found to be more efficacious when injected in the area from which lymph drains to the affected glands.—The relation of influenza to tuberculosis is the subject of a critical review which draws attention to recent doubts whether influenza predisposes to tuberculosis. There is a useful bibliography.

Giornale di Clinica Medica.—This new monthly periodical is published in Bologna under the editorship of Professor Umberto Gabbi, who founded it and issued the first number last January. Each number consists of about 50 pages printed on cream-laid paper in clear type. Besides original communications there are many abstracts from foreign sources arranged under headings such as therapeutics, infective diseases, cardiology, endocrinology, tropical pathology, &c.; these are particularly full and carefully done. In addition to notices of new books there are some items of general medical interest. The March number contains three original articles in reference to encephalitis lethargica. P. Guizzetti describes six autopsies of patients between 17 and 44 years of age who died from this disease after a duration of from 6 to 35 days. In the early cases there was hæmorrhagic encephalitis of the optic thalami and round the aqueduct of Sylvius; in the later cases naked-eye examination of the brain and spinal cord was practically negative. Microscopically there were accumulations of lymphocytes and pyroninophile cells (Pappenheim) in the perivascular lymphatic sheath and scattered foci of inflammatory infiltration. Investigations on micro-organisms proved negative. Professor Gabbi investigated personally the oculo-cardiac reflex in cases of encephalitis which occurred in an epidemic in Parma in 1919. He found that this reflex was markedly exaggerated and that this phenomenon also took place even when the cornea was anæsthetised by cocaine. Dr. Giuseppe Gotti describes an epidemic of cases of hiccough which occurred at Ravenna in December last, and was almost synchronous with an epidemic of lethargic encephalitis. In many cases of the latter there was a monomuscular clonus observed, comparable to the diaphragmatic clonus which characterised the previous epidemic of hiccough, which seemed to be due to some disorder of the central nervous system.

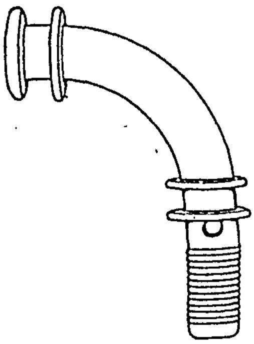
Rivista d'Ostetricia e Ginecologia Pratica. January, 1920.—This periodical enters its second year with this issue. The publication is of an eminently practical character and accepts contributions on obstetrics and gynæcology from all sources. Moreover, it publishes the proceedings and transactions of the Sicilian Society of Obstetrics and Gynæcology. Another feature is hat it limits its advertisement pages to products of ational industry, being convinced that Italy can hold own in this respect. The present number contains ommunications by Dr. F. Cusmano on a case of erforation of the Gravid Uterus at the Third Month with a Strangulated Cervico-vaginal Intestinal Hernia; by Professor F. Chidichino on a case of Vesicular Mole; and by Professor G. Giglio on the Trend of Maternity Help at the Present Day.

Acta Societatis Medicorum Fennicæ "Duodecim."—A natural corollary to Finland's re-birth as an independent State is the ambition on the part of Finnish scientists to publish their works under their own auspices. Hitherto works by Finnish medical men have largely received publicity at the cost of mersion, not to say submersion, in the medical journals of the chief European countries. Purely from the scientific point of view, this pooling of knowledge is praiseworthy, but the Nationalist point of view cannot be ignored, and it is obvious that the rôle of guest in the house of a stranger is apt to prove galling. In the past Finnish writers wishing to publish their works at home have found the medium of the Swedish and Finnish languages too cramped; they mean little or nothing to the world outside the Scandinavian countries. It seems, therefore, a wise compromise for Finnish scientists to publish an independent Finnish journal in English, French, or German according to the linguistic capacity of each author. All the papers in the first three volumes of "Acta" happen to be in German. Of their high scientific standard there can be no doubt. In the first volume Dr. J. A. Murto writes about Die Thermoresistenz der Syphilissora and Dr. H. R. Malmio about Das Alter der Menarche in Finnland. In the second volume Dr. Murto's paper is concluded, and Dr. B. Grönroos deals with Untersuchungen uber die Wassermannsche Reaktion bei der Primärsyphilis. The two papers in the third volume are anthropological, and deal with the development of the jaw in man and the length of the intestines in Finnish adult males. These five papers run to nearly 400 pages, and it is therefore a pity that the authors have not made a rule of printing a summary of their findings at the end of each paper as a concession to readers with limited time. The cost of each volume is provisionally put at 10 Fmk., and subscriptions and offers to exchange journals should be addressed to the Editor-in-Chief, Nervanderinkatu 8, Helsinki, Suomi (Finland).

New Inventions.

A TUBE FOR DRAINING THE BOWEL.

THERE is often difficulty in keeping a tube satisfactorily fixed in the bowel that would at once allow drainage of the latter to take place and prevent leakage occurring too soon. In many instances the tube slips out before it is desirable that it should do so, with all the inconvenience and risk that attends such a contretemps. After trying tubes of various kinds, it has been found that the tube illustrated in the diagram overcomes these objections. It is made of metal, has comparatively large flanges, between which the bowel can be sutured round the tube, tightly enough to prevent it from slipping, and yet not so tightly as to lead to a rapid necrosis of the coats of the bowel grasped in the suture-ligature. The chief feature of this tube, however, is the flexible, closely wound spiral spring which forms a continuation of the rigid tube, and lies in the lumen of the bowel. This acts as an internal splint, thereby overcoming the tendency of the tube to fall over to one side—an occurrence which, in the case of some tubes employed in this way, would appear to be the cause of them slipping out of the bowel. These tubes have been used in many cases spread over a number of years, and there has not been any instance in which a pressure necrosis of the wall of the bowel has been produced by the flexible portion. A large opening at each side of the tube allows for a free escape of flatus. In cases where the large bowel has to be brought out permanently, a tube having the spiral portion set at a right angle to the rigid part may be employed, as this shape permits the internal portion to lie outside the abdominal cavity. When dealing with a greatly distended small bowel, in cases of acute obstruction, it has been my practice for the last 25 years to empty the proximal bowel and return it into the abdomen, often with great advantage. At first I employed a rigid tube for this purpose, but many years ago designed one with a flexible part 9 inches long which has proved a great improvement over the rigid tube, in that it takes the turns of the bowel easily, and in consequence allows of a greater length of bowel being threaded upon the tube as the emptying process continues.



These tubes have been made for me by Messrs. Baird Bros., 97, Bath-street, Glasgow.

Glasgow.

THE LANCET.

LONDON: SATURDAY, APRIL 24, 1920.

International Health.

AN International Health Conference has been sitting in London at the Ministry of Health, the delegates of the Conference being as follows:—

Chairman.—Viscount Astor.

France.—M. Brisac; with M. Leon Bernard, M. Boujard, and M. Thiebault as technical advisers.

Great Britain.—Sir George Newman (when his other engagements permitted, but the Britain vote was left with Dr. Buchanan) and Dr. G. S. Buchanan, C.B.; with Dr. Steegmann as technical adviser.

Italy.—Dr. Lutrario, Dr. Fornaciari, and Dr. Druetti.

Japan.—Dr. Yoneji Miyagawa; with Mr. Kakichi Kawarata as technical adviser.

United States.—Surgeon-General Rupert Blue.

League of Red Cross Societies.—General Sir David Henderson, K.C.B.; with Colonel R. P. Strong, U.S.A., as technical adviser.

Office Internationale d'Hygiène Publique.—Dr. Pottevin.

The Belgian and Brazilian Governments were invited to send representatives, but owing to the alteration of the date of the Conference their delegates were unable to be present. The Secretaries of the Conference were Dame Rachel Crowdy (League of Nations) and Mr. L. G. Brock, C.B. (Ministry of Health).

There attended, as additional members for discussion of typhus in Poland, Dr. Chodzko (Vice-Minister of the Polish Ministry of Health), and Dr. Rajchmann.

The Conference was convened by Dr. ADDISON, British Minister of Health, at the request of the Council of the League of Nations, and its first purpose has been to consider the erection of an International Health Office under the League, roughly as a parallel to the International Labour Office provided under the covenant of the League and, moreover, recognised by the Peace Treaty. There is a clear statement in that covenant that the League of Nations would concern itself with international health, and in the knowledge that he would meet with the sympathetic support from other nations supporting the League, Dr. ADDISON convened a preliminary informal Conference last July. At this Conference a memorandum on the whole subject of the erection of an International Health Office under the League of Nations, setting out the lines on which it might be organised, had been prepared by the Ministry of Health, and was submitted last summer to representatives of the public health services of Great Britain, the United States, France, Belgium, the Office Internationale d'Hygiène Publique, and the League of Red Cross Societies, the steps being taken by the British Ministry of Health after consultation with the acting secretary-general of the League of Nations. A formal memorandum was then prepared and submitted for consideration, embodying general principles and ideas, and it was agreed that this more or less complete scheme should form the basis for subsequent discussions at which representatives of the provisional international secretariat of the League of Nations could be present. The formal conference having taken place last week, a formal scheme was drawn up to be submitted to a formal international conference, which it was hoped would be convened for the purpose by resolution of the Council of the League of Nations. This is the present position, and we have set it out in detail, as it is important that medical men should understand both the plans for the maintenance of health which it is proposed should be put into action under the covenant of the League of Nations, and also the deliberate and thoughtful actions precedent to those plans. And we may say here that the scheme arrived at is, in our opinion, suitable, far-reaching, properly comprehensive, and capable of extension to meet subsequent circumstances.

The scheme provides for the formation of an International Health General Committee, to consist at the outset of delegates appointed by all the Governments represented on the Committee of the Office Internationale d'Hygiène Publique, and of such nations as have not yet joined it, but are adherents of the League of Nations. It may, therefore, include representatives of Governments not as yet signatory to the covenant of the League of Nations, but who have signed the Convention of Rome of 1907—a very significant point when we remember the position of the United States of America with regard to the League, and of Japan with regard to the Office Internationale. The recognition of the Office Internationale d'Hygiène Publique, which has been sitting in Paris, has been rightly earned by much good work, as those who have read the notes on its Bulletins in our columns will recognise. Subject to the approval of the Governments signatory to the Rome Convention, the Office Internationale will form an important part of the new International Health organisation under the direction of the League of Nations. The General Committee will only sit as occasion may require, though not less than once a year, but a much smaller Executive Committee is provided for, to meet at least quarterly, with powers to settle questions requiring urgent consideration. On such matters the Executive Committee can appoint its own subcommittees, calling in technical advisers on special points. The chairman and members of this body are only elected for three years, but are eligible for re-election. To them will be committed the duty of choosing the medical secretary and the necessary staff, and they will be responsible for the conduct of the office at the seat of the League of Nations. They will be empowered to draft new covenants, to revise existing ones, and to conduct all the business of obtaining technical, trade, and other advice, and of reporting for the consideration of the Council of the League of Nations any default on the part of the members of the General Committee. For under the deliberations of the larger and controlling body all the conventions must come, each member having it as his duty to bring any new or modified convention before the authority within whose competence the matter lies.

The functions of such an International Health Office, as provided for in the scheme, open before us a vista of international health which has long been the ideal of all medical men. Medical men have seen from the moment that the idea of the League of Nations took shape in a practical form that their science would constitute one great thing whose international character could never be disputed. It is to the benefit of the world that the health of the world should be bettered, and that universal and harmonious schemes of prevention should be given full play. It is proposed that the Office should be constituted with the duty of advising the League of Nations in matters affecting the health of the world, bringing administrative health authorities in different countries into immediate relationship with each other. Rapid interchange of information will be secured thereby, when world-wide precautions against epidemics can be taken. A ready method for revising international agreements as to administrative action in matters of health will come into being, and international suppression of cholera, yellow fever, and plague can be undertaken, prompt action meeting new conditions as they arise. In two respects the International Health Office shows both a broad outlook and a sympathetic attitude in its proposals. First, the Office is to be advisory to the International Labour Office on health questions. We have only to think of the sections of the populations concerned, whose immediate and personal interests will be most nearly affected by health regulations, to see how necessary it is that international labour should be in full accord with international hygiene. If inside the League of Nations a new organisation, having international outlook, can agree on the policy which is alike best for health and best for labour, a large proportion of the administrative difficulties will disappear, and before various ratifying bodies persons who would otherwise have been disputants will find themselves joint advocates. That this will be so is further assured by the presence upon the Executive Committee of a representative chosen by the governing body of the Labour Conference. Secondly, it will be the duty of the International Health Office to advise with the League of Red Cross Societies. The obvious benefit to the Red Cross is that it will receive prompt information and practical help when measures have to be taken to deal with emergencies, while the splendid organisation of Red Cross can be employed to its full value by the League.

The scheme is full of promise, and we have a right to be proud of the conspicuous part played by British energy and foresight throughout the deliberations for establishing the International Health Office. This much praise of our Ministry of Health ought not to look parochial even to advanced internationalists.

◆

The Neutrophile Index.

THE Arneth reaction, to which Dr. H. A. TREADGOLD has drawn attention in a recent number of THE LANCET, has attracted little notice in this country, though it would appear to have considerable importance, especially in the prognosis of cases of pulmonary tuberculosis. This neglect may possibly be due to the laborious technique which the estimation of the index entails, for it demands more time and care than the clinical pathologist is usually able to afford. One observer states that he counted 40,000 leucocytes before his results coincided with those obtained by ARNETH, though after this intensive training he became proficient and had no further difficulties. The white cells in the circulatory blood number some 7000 in a cubic millimetre, of which about 5000 are neutrophile, or polymorphonuclear, leucocytes, and it is common knowledge that the total number and relative proportion of these cells may vary very greatly in certain pathological conditions. Indeed, the differential leucocyte count is one of the most valuable commonplaces of clinical pathology. ARNETH attempts to carry the matter a step further, and his reaction depends upon the recognition that the number of the lobes of the nuclei of the neutrophile leucocytes vary in certain infectious diseases, though in health they remain constant. This variation consists in the presence of an unusually high proportion of cells possessing single or bilobed nuclei, and a relative diminution of the types with three-, four-, or five-lobed nuclei. Expressed numerically, the Arneth index for normal blood would be 40:60, where 40 is the number of leucocytes of the first group, 60 that of the second group. In disease, for example in progressive pulmonary tuberculosis, an index might be 88:12, a variation which ARNETH describes as a shift to the left; very rarely the shift is to the right.

The explanation of this shift is still a matter for speculation, since we lack exact knowledge of the life-history of the mature blood leucocytes. The origin of the granular leucocytes from the parent tissue of the bone-marrow is well established. Under abnormal conditions lymphadenoid tissue may give rise to a certain number of neutrophile cells, but this accessory production is never of great importance, and in disease, as in health, the bone-marrow is the chief leucopoietic tissue. But while we know something of their origin, we know very little about the white blood cells after they enter the circulation. How long they survive and what is their ultimate fate are questions which still remain to be answered. Under normal conditions many leucocytes disappear from the body by emigrating on to the surfaces, especially of the respiratory and alimentary tracts. Others, presumably senile ones, are phagocytosed by endothelial and reticular macrophages in the spleen and the lymphatic glands. And in many inflammatory conditions, apart from an exaggeration of these processes, enormous numbers of leucocytes are disposed of in the form of pus. Similarly, our knowledge of the actual structure of these cells is far from finite, and it is by no means certain that the morphology of the mature leucocyte is constant. Some observers claim that the nucleus alters its shape during amœboid activity of the cells, though it is doubtful whether this alteration is ever fundamental, whether, that is to say, nuclear bridges ever become so attenuated during physiological activity as to simulate the fine filamentous connexions of the multilobed nuclei. The shape of the nucleus, however, may be altered by adverse physical circumstances—i.e., by over-heating; and, as a degenerative process, nuclear agglutinations may give rise to uninucleate forms, while the actual bulk of nuclear matter may be diminished by fragmentation with separation of small particles.

Two theories of the Arneth index are in vogue. According to one point of view it represents an increased proliferative activity of the marrow, and a consequent flooding of the circulating blood with young or immature leucocytes. The other theory ascribes the preponderance of the simpler type of cell to a disproportional destruction of the mature, more actively phagocytic leucocytes. Both these conceptions depend on the assumption that the age of the leucocyte may be deduced from the degree of lobulation of its nucleus. It is probably true that the maturity of the cell can be deduced from the actual bulk of nuclear matter present. Thicker segments and broader bridges indicate a younger cell, while smaller lobes with delicate filamentous connexions suggest senility. Beyond this, however, it is scarcely justifiable to go. Again, the suggestion contained in the second theory that phagocytic activity is the prerogative of the mature or even senile cell is, on the face of it, not highly credible. Of even greater theoretical importance is the question why the Arneth shift to the left should occur at all in tuberculosis. A leucocytosis is a definite expression of an immunity reaction on the part of the body, and is called forth by a variety of toxic agents, particularly the toxins of certain microbes. But the tubercle bacillus, like the organisms of typhoid fever and certain other infections, calls forth no neutrophile leucocytosis, and the modern tendency is to look on the lymphadenoid tissues as the ones chiefly concerned in the immunity response. It is difficult to understand, therefore, how a pure infection with the tubercle bacillus can so disorganise leucopoiesis as to affect the neutrophile leucocyte. Neither of the current theories is adequate to explain this, and it is clear that much work remains to be done before we can dogmatise on the subject.

The Budget.

THE Budget, introduced by the Chancellor of the Exchequer on April 19th, calls upon us all to sustain the finances of the country as best we can. Increased taxation in many directions reflects the price of national safety, and implies also personal sacrifices in many directions. We are glad to note that, generally speaking, the necessaries of life have escaped the Treasury net. Beer, wine, and spirits will cost the consumer more, and in some instances the increased taxation on such commodities is very heavy, the receipts from these sources being estimated at an advance of approximately eighty millions. This decision may well have a marked effect in diminishing the consumption of alcoholic liquors. Postage will cost more, and there will be few, even to the poorest, exempt from this burden. Proprietary medicines, which are curiously bracketed in the same category as playing cards and coffee mixtures, are anticipated to yield a sum equal to that of the previous financial year. In regard to motor vehicles, taxation as from January, 1921, is to be based on weight in the case of those used for trade purposes, upon seating capacity in the case of hackney carriages, and upon horse-power unit in the case of ordinary cars. In this connexion it may be noted that the abatement of duty granted in the case of motor cars used by medical practitioners or veterinary surgeons will cease on the same date, when also the motor-spirit duty will be abolished. Medical men therefore cease to receive preferential treatment in respect of the purpose for which they use their cars. The chairman of the Medico-Political Committee of the British Medical Association points out in a letter which appears in the current *British Medical Journal* that the medical profession will be injuriously affected by the proposed changes. Their cars are used exclusively for purposes of medical practice, many of them having a nominal power which is much exaggerated by the R.A.C. formula. If all rebates are abolished the extra cost to the owner of a 21 h.p. car (R.A.C. rating), doing a mileage of 7500 in the course of the year, will be £11 12s. On a larger mileage the extra cost, of course, decreases pro rata. Rural practitioners may further suffer from the necessity of keeping two cars in order that they may not be prevented attending an urgent call owing to a car breakdown. Also of some medical interest is the fact that the Chancellor has found an increased source of revenue in tobacco, which he attributes partly to the popularity of cigarette smoking amongst women. No harm to the nation will result from a diminution in this indulgence, at present carried to grave excess by both sexes. Substantial relief in income taxation is proposed in the case of families with moderate incomes. On the whole, the financial proposals seem framed on democratic and reasonable lines, having regard to the colossal financial requirements of the country. It would be anti-social to find fault with the general policy of the Treasury, which seems aimed most at the resources of those who still live comfortable lives and have something over.

Annotations.

"Ne quid nimis."

THE APPROVED SOCIETIES' VIEW OF STATE MEDICAL SERVICE.

AT the recent annual conference of the National Health Convention of the Association of Approved Societies a resolution was carried in favour of substituting a comprehensive State Medical Service for the existing panel system and public health services, in order to secure to the whole population at the national expense the most efficient and complete service that medical, surgical, and dental science can offer. The resolution gives in effect the most recent and explicit definition of what is implied in a State Medical Service—namely, the abolition of private practice, and the establishment of medical treatment provided by the State for all citizens. There is, indeed, much to be said for a non-contributory service to which all are entitled by virtue of their citizenship, and financed by a special public-health rate contributed in a manner similar to the education rate. It is already obvious that for a majority of the population medical treatment must be State-aided. The health of the individual has become the concern of the State and cannot be left entirely to individual responsibility. So far, so good. But the fallacy in the propaganda of the Approved Societies is the implication that the panel system is incompatible with a comprehensive and up-to-date medical service. Great extensions of the system are in contemplation, and it is of the first importance for the public to understand that these aim at providing a really efficient service at the hands of medical men who are general practitioners and who will retain a large degree of independence. The clinical practitioner responsible for the treatment of the individual citizen must not become an official person; he should maintain his present intimate relationship to his patients. As far as practicable the free choice of practitioner should be preserved to the citizen, and the scope of choice can be enlarged beyond its present range if treatment is centred at clinics where a number of practitioners are congregated. The Approved Societies demand a State Medical Service in which it appears that the doctors are to be salaried officials. We may ask: Are they prepared to merge themselves into a State Approved Society, a change which would appear desirable in the interests of efficient registration and control?

CLINICAL KINEMATOGRAPHS.

OF the value of the kinematograph film in education there can be no doubt, and recently an attempt has been made to employ the same appliance in the instruction of the medical student. It is clear that the method is likely to prove more widely useful in surgery than in medicine, for the medical conditions which can be usefully demonstrated in the kinematograph are somewhat limited. The ataxic gait can, indeed, be well shown, and various other nervous phenomena are equally easily demonstrable, but it is in the representation of surgical operations that the utility of the method will be most manifest.

A private demonstration was given last week by the Selig Film Company, in connexion with the Phillips Film Company, of some of the possibilities of the kinematograph in the teaching of surgery, when some excellent films were shown. The operation of gastrostomy was the first exhibited, the surgeon whose operation had been photographed was Dr. H. Lilienthal, and the several stages were very clearly seen. Another film exhibited was the placing on an inlay bone-graft to fix a chronic tuberculous knee-joint, by Dr. F. H. Albee. Here the use of the twin saw in cutting the inlay was excellently represented. This was done before the knee-joint was opened in order to avoid the risk of infecting the healthy bone. When the diseased joint was laid open portions of the femur and tibia were removed, the trough for the inlay was cut, and the insertion of the inlay followed; it was fixed in position and the wound was closed. A plaster splint was then applied. In this, as in the other films, the several stages were preceded by a short account shown on the screen of what was about to be done. Other films followed, and it may be said that, on the whole, they were all excellent. Each member of the audience—if we may apply that term when there was nothing to hear—could see perfectly the details of the operation—better, indeed, than if he had been present, for in nearly all operations there are only two persons who see everything that takes place—the surgeon and his chief assistant. And, indeed, it must be so; any attempt by the onlookers to get close enough to see everything would manifestly interfere with the operation. The camera is under no such disability; it is placed, in nearly all cases, above the table entirely out of the way of those taking part in the operation, and there it is able to record with perfect fidelity all that takes place. Films such as those shown at the private view cannot fail to provide valuable instruction to all studying the subject. Each film can be passed through the lantern at any speed desired, and the demonstrator can direct that it should travel slowly when it is wished that the details should be especially clearly seen. He can point out what is of importance and explain the reason of everything that is done. There is not the slightest difficulty in having the film passed once more through the instrument, if the demonstrator wishes to hark-back to some point which has not been fully understood. We are told that there are some 600 films already prepared, and the number is being added to every week. Most of the leading surgeons of the United States have provided films in this series, and if we may judge of those we did not see by those that were shown their value must be very great. The company is willing to record the operations of any surgeon for his private use in teaching his classes, so that the students can see, before an operation is done, what the surgeon intends to do, and thereby they will gain much more advantage from seeing the operation itself than if they had not learned beforehand what they were to expect.

There are certain parts of an operation the repetition of which would be tedious; thus the suturing of a wound is of comparatively little interest in most cases, though sometimes the method in which it is done is of importance. Ordinarily, therefore, only the commencement of a suturing is shown and then there is a sudden jump to the completion of the suture. We would not be considered hypercritical, but there is one point in which we would suggest a definite improvement. We acknowledge freely the extreme value of the method as exhibited to us, but the absence of colour cannot but deprive the exhibition of these films of some of their value. To see black blood flowing from the wound is certainly curious; moreover, the onlookers cannot distinguish clearly the different tissues, and we feel sure that coloured films of operations would quite double their value. Even as they are the results are excellent. We are well aware that to obtain coloured films would slow the action somewhat, but we feel certain that this improvement must come to pass.

RECOVERY FROM ADDISON'S DISEASE.

Dr. Raymond Giraudeau[1] devotes his inaugural thesis to the description of a case of Addison's disease, which ended in recovery, death occurring 11 years later from cancer of the stomach, when the autopsy confirmed the original diagnosis. The patient was a man, aged 39, the subject of chronic alcoholism, who on admission to hospital in November, 1901, presented well-marked asthenia, pigmentation of the skin, and buccal mucous membrane, diarrhœa with abdominal pain, and a feeble pulse. On Jan. 4th, 1902, he was given an injection of suprarenal extract, and the injections were continued for 12 days. Improvement took place in the general condition, and there was a marked increase in weight. The injections were resumed on Jan. 27th, when the abdominal pain and diarrhœa were very violent. On Feb. 1st the pigmentation had considerably diminished, and during the next two months disappeared from the skin and from the palate. The general condition of the patient had meanwhile improved so much that he was discharged in the summer of 1902. Except on an occasion when he was interned for an attack of alcoholism in June, 1904, he was lost sight of till February, 1913, when he was admitted to the asylum for another attack. Death took place on March 13th. Apart from carcinoma of the pylorus with metastases in the liver, the only lesion found post mortem was some scar tissue in the right suprarenal, indicating the occurrence of inflammation many years previously. The nature of the lesion could not be determined. There was no evidence of tuberculosis or syphilis in the other organs. Dr. Giraudeau comes to the conclusion that in cases in which generalised and transient suprarenal incompetence is the result of a localised inflammatory lesion treatment may be effective, whereas it is of no avail in caseous tuberculosis of the suprarenals.

INFANTILE DIARRHŒA AND VOMITING.

IN his article on p. 906 Dr. G. Douglas Sherwood calls attention to a subject of great contemporary importance. He claims that both diarrhœa and vomiting in infants are practically always of infective origin, and that both symptoms, either singly or in combination, can be prevented by certain antiseptic and aseptic precautions. It is satisfactory to learn that in Upwick Vale Home, where these prophylactic methods have been adopted, and from which the data of this paper are drawn, the system has given such favourable results, for similar attempts in other institutions both in England and on the Continent have proved signally ineffective in the prevention of epidemics of diarrhœa. The management of any large number of bottle-fed infants in one and the same ward appears to present difficulties which are directly proportional to the number of the inmates and indirectly to the number of nurses employed. Whether the infection is conveyed by direct means or is air-borne does not appear to be proven at the present time, but in either case the prophylactic measures described by Dr. Sherwood would meet the necessities of both cases, provided the technique is carefully observed. Good as are the mortality figures given by Dr. Sherwood as obtaining in this home, it is not justifiable to compare them with the general mortality-rate of the whole population without giving details as to the age of the infants and the number of breast-fed as compared with bottle-fed infants. Similar claims have been made with respect to results obtained in welfare centres, which are, as a rule, exempt from the unflattering mortality which occurs during the first few weeks of life and which, of course, greatly raises the general mortality rate. No doubt the prophylactic technique employed at the home in question is not unnecessarily elaborate in the case of institutional management, if it is to prove at all effective; but it is questionable whether it would prove practical or indeed necessary under ordinary domestic conditions in which the infant is more or less isolated and is only exposed to the risk of autogenous infection—if indeed this is so serious a risk as is implied in Dr. Sherwood's paper. We are not greatly impressed with the theory of the infective character of most cases of vomiting. This symptom is so essentially controllable by dietetic means, and so rarely occurs when the intervals between feeds are adequately prolonged, that we hesitate to believe, apart from its complicity with diarrhœa, that it is associated with an infective ætiology.

THE MYTH OF BACTERIAL LONGEVITY.

THERE is, perhaps, no well-established fact which the laity finds more difficult to grasp or to believe than that bacteria are present, sometimes in immense numbers, on every particle of material substance with which we come into direct contact. The failure to grasp this has sometimes a material consequence. How often have we not seen even trained persons sterilise an instrument and then undo their work by touching it with the unclean hand? The immaterial consequences which may flow from the inability to conceive how widespread is the distribution of bacteria are more difficult to define; the direction of a man's thought may be influenced by his proneness to accept as proved statements which the most elementary knowledge would show to be improbable. If an announcement were made in a reputable scientific journal that living spores had been found in an Egyptian mummy, and the conclusion drawn that the spores had lain dormant a couple of thousand years, we should be entitled to doubt the accuracy of the observation; we should remember that it is difficult to take a sample of any substance without introducing one or two extraneous organisms. The observation would have to be made repeatedly and by more than one competent technician before we should be expected to accept the statement. The difficulties of avoiding contaminations are ever present to the bacteriologist, and they breed a healthy scepticism of any "marvellous" results. The solution of problems of vital philosophical importance, as, for example, the question of the spontaneous generation of life, has depended upon the satisfactory avoidance of accidental contaminations. We are led to make these rather platitudinous remarks after reading a leading article in the *Daily Telegraph* of April 13th, in which the "Immortality of Microbes" is discussed in an agreeably discursive way. A thin and tenuous web of fancy is spun round the reported discovery, to which our Paris correspondent also calls attention this week, by a French savant of living microbes in amber. It would be a breach of good manners, and would expose us to the horrid charge of lack of a sense of humour to subject such a pleasantly written essay to sober criticism. We content ourselves with expressing doubt as to the existence of these million year old microbes, and to pointing again to the possibility of contamination with organisms born but yesterday. The popular sense of wonder at the beauties (and the horrors) of nature demands satisfaction, sometimes in a grotesque and sometimes a refined and literary form which our newspapers supply. The solid satisfaction which comes from exact knowledge must be preceded by close and hard study, and is enjoyed by the few.

---

SCHOOL MEDICAL ADMINISTRATION IN SCOTLAND.

The Scottish Board of Health has taken over the powers and duties of the Scottish Education Department in regard to the medical inspection and treatment of children. This fact was briefly recorded in The Lancet of April 10th, and it may be well to consider further some of the important issues involved. In the first place, the actual carrying out of the inspection and treatment continues to devolve upon the local education authority whose duties are not altered in principle by the new relation established between the Board of Health and the Education Department. In its memorandum, which deals broadly with school administration in general, the Board of Health, however, urges close coöperation locally between the public health and education authorities. The latter are enjoined to appoint their school medical officer as administrative head of all services coming under the scope of school head administration, and this, if carried out, would be a great step forwards in unification. In the majority of Scottish areas the county medical officer is already school medical officer; it would be all to the good for the junior dual position to be held by the local medical practitioner, who is the one person trusted alike by parents and children. At the moment, possibly, he may not hold the diploma of public health which the Board of Health regards as indispensable, but it must be admitted that this diploma is now of little use to the school officer. It serves, however, as a proof that the holder's attention has been turned in a special manner to public health problems. In a decade or two the scope of the diploma will have been altered, and then the practitioner will be found glad to avail himself of the curriculum in public health. He will then learn the right way to control an epidemic of scarlet fever, of measles, or of diphtheria, and closure of schools for infectious disease will become as extinct as the dodo. He will learn how to diagnose and classify children according to their mental capacity, and he will gain facility in determining mental deficiency. In the meantime it is to be hoped that the Board of Health will not sacrifice its splendid ideal of administrative coöperation by urging local authorities to exclude the undiplomate practitioner.

As regards the school medical work, the Board of Health's memorandum lays stress on preventive work, suggesting three routine medical examinations for the child in the primary school, although the authority may, if it wishes, institute a greater number. Re-examination of defects, and examination of special cases presented by teachers, along with treatment and examination after treatment, will, in any case, keep the staff fully occupied. For the higher grade and secondary schools one examination at least is suggested, at or about 17 years of age, the period of adolescence when the child's metabolism is undergoing so radical a change. An examination made then may avoid the necessity for a change of career later. It is encouraging to note that the Scottish Board of Health frankly recognises the futility of laying down a uniform procedure for all education authorities. Scattered and sparsely attended schools in the Highlands and Islands cannot squeeze into the same mould as those in the densely populated districts of Renfrewshire, and much is left to local discretion; in the case of remote schools with an average attendance of under 30 pupils the obligation resting on the school doctor to pay two regular annual visits no longer holds.

Another point to which prominence is given in the memorandum is the following up of the work of the school doctor by the school nurse. The school nurse might be a much more effective factor in the service than she has hitherto been, whether in Scotland or England. This is to be done by combining in the person of the school nurse the functions of tuberculosis nurse and visitor, child welfare worker, and other duties of a similar kind. No one is better fitted than the right sort of district nurse for the particular area to coöperate with parents, children, and doctor in matters of personal and public health. When it comes to inspecting heads nurses might avoid odium by a temporary exchange of district. The Board desires each education authority to draw up its own scheme for medical inspection and treatment without delay, the memorandum serving to indicate the general lines to be followed, while still leaving scope for individual enterprise.

CREDÉ'S METHOD AND PUERPERAL SEPTICÆMIA.

Suggestions as to the Causes of the Persistence of Puerperal Septicæmia since the End of Pre-antiseptic Times is the title of an interesting paper by Dr. D. Berry Hart in the *Edinburgh Medical Journal* for April, 1920. The author states that now and for some time the mortality has not fallen in Great Britain and Ireland much below pre-antiseptic times as far as 1822. Two factors are given in the production of puerperal septicæmia—the first, imperfect asepsis and antisepsis; the second, defects in labour technique on the part of the obstetrician. The latter is specially discussed in this article. The method of expulsion of the fœtus is given, and the author shows that the "final passage of the head is in some respects disadvantageous and requires careful handling." Careful guarding of the perineum is necessary and in elderly primiparæ episiotomy is useful. The mechanism of the third stage of labour is then discussed, and the author's well-known views on this subject are given in detail. He regards the Credé practice as a great misfortune in the technique of the management of the third stage, the danger being that small pieces of placenta and larger pieces of membrane may be left in utero, with septic infection following. The author imposes on himself an hour limit before interfering if hæmorrhage is not going on. Careful examination of the placenta and membranes is very important, and the writer recommends that a record should be kept of the state of all placentæ and membranes and of their relation to morbidity and mortality.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THE annual congress of this body, to be held from April 29th to May 1st at the House of the Royal Society of Medicine, promises to maintain a high standard of interest. The programme includes numerous papers, a clinical meeting, a visit to the special hospital of the Metropolitan Asylums Board for cases of ophthalmia neonatorum, with a discussion on the prevention and treatment of that disease, another discussion on Diabetes in Relation to Diseases of the Eye, and a dinner. Full details will be found in our Medical News column.

THE PHYSICAL SIGNS OF FOREIGN BODIES IN THE BRONCHI.

IN the *American Journal of the Medical Sciences* for March Professor Thomas McCrae, of Philadelphia, has published a careful study of the physical signs of foreign bodies in the bronchi in a considerable number of cases. The opportunity to examine the patients was given to him by his colleague, Professor Chevalier Jackson, a laryngologist, whose experience of foreign bodies in the air-passages is unrivalled. It might be supposed that a foreign body could not pass into a bronchus without producing symptoms which must be noticed. But this is not so. In one case an atomiser tip had been aspirated and the patient knew nothing of it. All that he could remember was that 18 months ago the tip had disappeared. He was thought to be suffering from tuberculosis. A boy of 8 was sent for some laryngeal condition and part of a collar button was found in a bronchus. No history of any acute onset could be obtained. Professor McCrae's impression is that such cases are by no means rare, and that foreign bodies in the bronchi are much more common than is generally supposed. The greatest difficulty of diagnosis arises when the body cannot be recognised by means of the X rays. These cases probably number from 10 to 15 per cent. of the total. There are two groups of unrecognised cases. In one the body sets up acute inflammatory changes which are soon fatal, and pneumonia is generally diagnosed. These cases particularly follow aspiration of some kind of nut by a young child. In the other group the symptoms become chronic, and pulmonary tuberculosis or bronchiectasis is diagnosed. In the physical signs there is great diversity. A closed safety-pin is not likely to cause much change in a short time, while a screw or tack, which plugs a bronchus, produces rapid changes. A body may plug a bronchus at one time and not at another, so that the signs vary. If this occurs at a short interval it is a striking point. Thus in one case the signs suggested collapse of the involved lobe and a few hours later it was apparently overdistended, which raised the idea of valvular action. The signs may be local or general; signs over both lungs are not uncommon, and they may be more diffuse on the unaffected side, which may lead to serious error. The only sign which was present in every case examined by Professor McCrae was decreased expansion on the affected side. It may be the only sign. In some cases râles, which may be termed characteristic, were heard over a small area. These may be described as very fine and softer than the early crackling râles of lobar pneumonia. They may be compared to the crackling of fine tissue paper. Pneumonia is often diagnosed, but a careful study of the signs should prevent this error. Fever is common after aspiration of a foreign body, and if there is dyspnœa with cough and bloody or blood-streaked sputum pneumonia is suggested. Decreased expansion and dullness may bear out this view, but a careful study of the vocal fremitus and the auscultatory signs should show that if there is pneumonia there is also plugging of the bronchus—a rare condition. In many cases no breath sounds or râles are heard over the affected parts; in others there may be râles but no breath sounds. Later, fibrosis, abscess, and bronchiectasis may be found. Professor Chevalier Jackson has called attention to a new sign of foreign body in the trachea or bronchi,[1] which he termed the "asthmatoid wheeze." It is heard with both inspiration or expiration, but sometimes only at the end of forced inspiration, on placing the ear or bell of the stethoscope over the patient's mouth. This sign is of considerable value, particularly when the foreign body does not show in the radiogram. Certain foreign bodies, particularly the peanut, set up very acute and dangerous changes in children. The clinical picture is rather distinctive and is one of œdematous, purulent tracheo-bronchitis, which often results in pulmonary abscess. The dyspnœa is extreme, cyanosis is usually marked, and there may be purulent tenacious sputum. The only distinctive signs which Professor McCrae finds of foreign body in the lung are "the asthmatoid wheeze" and the "tissue paper râles" heard over a small area.

THERE will be a meeting of the United Services Medical Society in the Library of the Royal Army Medical College, Grosvenor-road, S.W., at 3.30 P.M. on May 28th, to discuss the proposed amalgamation of the society with the War Section of the Royal Society of Medicine.

A MEETING of the Executive Council of the Federation of Medical and Allied Societies will be held at 11, Chandos-street, London, W. 1, on Tuesday next, April 27th, at 4.30 P.M., when the special business to be considered includes the urgent need by legislation for the efficient treatment of mental disorders in their early stages (submitted by the Medico-Psychological Association), and the steps which should be taken to secure for the nursing profession representation on the Consultative Council of Medical and Allied Services of the Ministry of Health (submitted by the College of Nursing).

LONDON PANEL: POST-GRADUATE STUDY.—Beginning in May it is proposed to hold a course of lectures and demonstrations on laboratory methods in connexion with the prevention, diagnosis, and treatment of disease, which will be given by Dr. W. W. C. Topley, director of the pathological laboratories at Charing Cross Hospital on Thursdays at 9.30 P.M. The fee for the course will be £3 3s. and certificates of attendance are to be given. Other courses are being arranged for the near future.

---

[1] THE LANCET, Dec 14th, 1918, p 824

THE
CHINA MEDICAL MISSIONARY ASSOCIATION CONFERENCE AT PEKING.

DURING the first week of March there was held at Peking a highly successful Conference of the China Medical Missionary Society and the National Medical Association—170 doctors of the former and 65 of the latter society taking part.

Problems of Mission Hospitals: Medical Education in China.

Dr. C. J. DAVENPORT, the President, of Shanghai, in the opening address, surveyed the outstanding work of the Conference since it last met. He referred to the leading features of medical work in China, to the greater spirit of coöperation that now prevailed, to the prominence of women in the medical work, and to the advance of medical education amongst the Chinese. He was followed by Dr. WU LIEN TÊH, President of the National Medical Association, a body of foreign-trained Chinese medical men, who stated that the desire of his society was to work at all times in coöperation with their foreign colleagues.

The Conference then dealt with various problems of mission hospitals in China, Dr. SNELL speaking of the city hospital, Dr. A. C. HUTCHESON on the up-country hospital, Dr. H. S. HOUGHTON on hospital accounts, and Dr. R. C. BEEBE on coöperative supply organisation. In the afternoon sectional meetings were held, the section of most general interest being that devoted to anatomy and anthropology. Dr. S. P. CHEN read a paper on the Attitude of the Chinese Government towards Dissection. It showed that the Home Office officials now recognised the necessity of practical anatomy for students, and were willing to authorise the supply of unclaimed bodies, but were hampered to some extent by popular feeling, which is still far from favourable in this respect.

Medical education occupied much attention, the necessity for approximating the standards of teaching and examination to those of Western countries being recognised, while the practical application of these ideals was seen to present formidable difficulties, especially in schools which teach in Chinese. Representatives of the Ministry of Education presented papers on the Government Medical Curriculum.

Dr. CHOU WEI-LIEN, Director of the Government Animal Experimental Station, read a paper on the Milk-producing Powers of Different Cattle, more especially of the Mongolian Cow, and gave statistics which showed the increasing demand for milk by the Chinese, who are not nationally a milk-drinking race.

The Work of the Sections.

In the General Medicine Section Dr. W. W. CADBURY gave a paper on the Treatment of Leprosy, describing the work he had done on the subject. Most of the speakers who followed him were rather pessimistic on the matter of any specific cure. Papers were also read by Dr. R. R. ROSS on Insanity among Chinese, and by Dr. J. KIRK on Tetanus Neonatorum.

In the General Surgery Section Dr. OSCAR THOMSON dealt with the subject of Vesical Calculus, based on 3000 cases operated upon in the Canton Hospital. Discussion centred chiefly round the ætiological factor and choice of operation. The paper read by Dr. J. A. B. BRANCH on the Treatment of Empyema by Dakin's Solution, based on the experience of 100 cases, showed how highly successful the results had been, but in the subsequent discussion the main difficulty to doctors in charge of "one-man-hospitals" was stated to be the exact preparation of Dakin's solution.

A good deal of the Conference's attention was devoted to public health problems. Dr. S. WOO dealt with the work of the last few years, showing the immense strides that had been made in the education of the public and giving some idea of the amount of literature which had been circulated in China. Dr. W. W. PETER also read a paper on this subject, and daily gave kinematographic displays of health subjects, including a very telling film of venereal disease and its ravages.

Methods of Anthropometry was the title of a paper given by Dr. A. HRDLICHA, who made an appeal for the collection and recording of the valuable information that anthropometrical records in China would yield. Demonstrations were given on preparations of mitochondria in the somatic cells of ascaris, by Dr. SHUNICHIONO, of Japan; on experimental alterations in the mitochondria of plant cells, by Dr. N. H. COWDRY; on the interstitial cells of Sebright testes, by Dr. ALICE BORING; and on schistosoma larvæ in men and other animals, by Dr. E. C. FAUST.

A most interesting paper was read by Dr. E. T. HSIEH, entitled "A Review of Chinese Anatomy from the Period of Huang-ti (Yellow Emperor, 2697 B.C.)." Numerous illustrations of the philosophical conception of human anatomy current throughout this long period were shown, and the speaker pointed out that little or no advance had been made in this science in China since the Ming Dynasty, for the reason that the accurate study of human material has at no subsequent date been possible.

DR. H. J. HOWARD read a paper on the Origin of the Vitreous Humor in the Human Eye. He discussed the various current theories as to the origin of the vitreous, in the light of his findings in an eye enucleated for suspected glioma. Evidence of the double origin of the vitreous from mesodermal and ciliary sources was presented. In the discussion which followed, the importance of early recognition of such cases was pointed out, also their bearing on the prognosis in the case of congenital cataract operations.

Professor M. INOUYE, of Tokio, gave a paper on the Muscles of the Soft Palate. His investigations were carried out by means of dissection, microscopic examinations and reconstruction, and experimental and clinical observations. A most interesting result has been obtained—viz., that the M. uvulæ is innervated, not from the pharyngeal plexus as described in current text-books, but by way of the palatine nerves, ciliary ganglion, and second division of the trigeminal nerve. The passage of motor fibres to this muscle, by way of the petrosal branch of the facial, was excluded, and movements of the palate were elicited by stimulation of the peripheral cut end of the trigeminal.

A somewhat remarkable feature of the Conference was the evidence given by young Chinese medical men of the way in which they are taking up and furthering the cause of scientific medicine. In fluent English demonstrations were given and papers read by Dr. HENG LIU on Blood Grouping and the Technique of Blood Transfusion; by Dr. T. M. LI on Practical Considerations in Eye Refraction; by Dr. WANG LING NEW on Treatment of Uterine Fibroids; and by Dr. HUA LIU on the Comparative Anatomy of the Mastoid Process.

Diseases and Epidemics Met With in China.

On the fourth day instructive papers were read dealing with the diseases and epidemics met with in China. Dr. J. W. CHUN and Dr. L. T. WU dealt with the management of the last cholera outbreak at Harbin, where the Chinese Anti-Plague Service had well-equipped laboratories and hospitals. In 1962 cases, by the systematic use of Roger's hypertonic saline infusions, the mortality was brought down to 14 per cent. Dr. BRAFLADT made an analysis of 100 cases of cholera seen at Tsinanfu and urged the extensive use of kaolin (bolus alba). He gave as much as 800–1200 g. daily to each patient and used infusions only for severe cases.

Dr. P. T. WATSON read an interesting paper on Bubonic Plague in Shansi, in which he doubted the essential factor of rat-fleas as a cause of plague. He thought that human fleas might transmit it direct from one person to another, and recommended a widespread prophylactic vaccination among the people, for which purpose the Manchurian Anti-plague Bureau might be invited to extend its activities to other parts of China. Papers were also read by Dr. VAN BUSKIRK (Seoul) on the Diet of Koreans and by Dr. S. D. WILSON on the Diet of Chinese. The former pointed out the low caloric value of Korean diet, which is mainly vegetarian—rice, barley, and beans are consumed, but fat and meat are rarely eaten, the result being a dilated stomach and poor efficiency. The speaker referred to the greater vitality of white people, the result of their higher protein consumption. Dr. WILSON pointed out that ordinary bean curd, which is an important item of Chinese dietary and regarded as akin to cheese, has 86 per cent water and 14 per cent solids (which contain 21 per cent fat, 60 per cent protein, and 6 per cent. ash) as against our European cheese, which has 38 per cent water and 62 per cent solids In many schools he found scarcely any protein or fat given, the diet consisting mainly of a little cabbage, white Chinese bread, white rice, and some salt and radishes

At the next session Dr WU LIEN TEH gave an address on the Latest Phase of the Narcotic Problem, in which he showed figures representing the enormous increase of morphine injection in China, brought about by unscrupulous Japanese traders and British and American manufacturers The amount had increased from 5½ tons in 1911, 14 tons in 1914, to nearly 28 tons in 1919. Both Edinburgh and London firms of high standing were implicated, as was proved by samples of covers which were shown The Conference passed a resolution urging that immediate action should be taken for the better control of the production of opium and for the limitation of the manufacture of morphia and other derivatives to a quantity not exceeding that necessary for legitimate medical purposes

The Rise of Scientific Medicine in China

On the last day of the Conference the members with their wives attended a reception in the palace of President Hsu Shihchang The President addressed them in a speech referring to the great humane work which they had done throughout China, and spoke with emphasis on the progress of Western medicine and the benefit it could bring to the people This was followed in the evening by a banquet at the Army Medical College, where further complimentary speeches were made

The Chinese Government has shown much appreciation of the work which is being done, and a new era has been entered in which scientific medicine and surgery are no longer regarded with suspicion and animosity The founding of the China Medical Board (the Rockefeller Endowment), Hong Kong University, Chinanfu, and other medical colleges, has brought about a real awakening It is a movement which has come to stay, as evidenced by the numbers of Chinese students now entering the medical profession This Biennial Conference has brought to notice the part being played all over China by medical missionaries, British and American, in the cause of medical education It has also stimulated the delegates to further observation and research in a field which opens boundless opportunities for useful contributions to present day medicine

MEDICINE AND THE LAW

Sentence on a Professional Abortionist

AT the Central Criminal Court recently, Mr. Justice Shearman passed a sentence of ten years' penal servitude on Devi Dayal Sasun, L R C P. Edin , 1902, a native of India, practising medicine in the East End, for manslaughter The indictment was for the murder of a woman whose body was found in an archway at night near the prisoner's house The case for the prosecution was that the woman had asked Sasun to procure her miscarriage, and that immediately after he had operated on her with that intent, had died from shock in his surgery In order to conceal the crime he had carried the body to the place where it was found, and called the attention of the police to it, as though he had observed it casually in passing The evidence of Dr. B H. Spilsbury was to the effect that the woman died from the shock of the operation as stated above, and that though such an occurrence was rare, he had had experience of five similar cases. For the defence Dr. H. R Andrews, Mr Comyns Berkeley, and Dr. J. S. Fairbairn expressed opinions adverse to that of Dr. Spilsbury, to the effect that death from shock in such circumstances was so rare that it must be accounted as out of the question that it should have been caused by the operation in the case before the court.

More might have been heard of this view if the conviction had been one of murder and not of manslaughter. The latter verdict is not one strictly legal or logical, in that to cause death in the commission of a felony constitutes the crime not of manslaughter but of murder. It is, however, sometimes found, and it gave occasion for the police to go into the prisoner's record and antecedents, which were of such a character that the question whether in this particular instance his conviction was justified by the scientific evidence must to him, at any rate, have become unimportant Not only was there another indictment on the file which was not gone into, but the police had found on Sasun's premises documents which showed, when followed up, that he had procured, or had attempted to procure, abortion in a number of women It need only be pointed out that a single conviction in one of these cases would have rendered him liable to penal servitude for life, and, as a matter of fact, conviction in all of them, with cumulative sentences averaging ten years in each, would have involved condemnation to penal servitude for 1160 years!

A Remarkable Impostor.

At Liverpool Assizes recently Mr Justice McCardie passed a richly deserved sentence of five years' penal servitude upon a man named Richard Thomas Cubbin, who for many years and in various places has preyed upon the public with singular effrontery and equally remarkable success Cubbin was stated to have been the son of a collier and to have worked as such himself, losing a leg by an accident Since 1895 he had lived much abroad and had practised as a medical man. He is a married man who, having deserted his wife, has gone through the ceremony of marriage with other women in order to rob them. In one instance he persuaded the widow of a medical man who had died at sea that he was her lost husband returned to her after three years' interval His past sentences included one of penal servitude for bigamy and another for posing as a medical man and giving certificates of death In the present instance the sentence was for forgery and giving death certificates, offences committed at Blackpool and Wigan The epithet remarkable has been applied above to the success of this rascal's operations, because he was stated at his trial to have obtained posts as an assistant to medical men not only under an assumed name, Sir Alexander Thomas Munro, not in the Medical Register, but under the guise, unusual in such candidates, of a baronet a "colonel surgeon," a brigadier general, and a K B E , combinations of these titles appearing upon cards used by him. He even exhibited a coronet upon his stationery. This last peculiarity on the part of an alleged baronet may have helped to bring about Cubbin's undoing, but it is suggested that the other impostures, or any one of them, should have been enough. Medical directories, medical registers, army lists, and books of reference containing the names of baronets, with other particulars about them, are fairly accessible everywhere, and can be consulted without any possibility of hurting the feelings of a genuine candidate for a vacant post

Witnesses Under Subpœna and Expert Evidence

In an action tried recently in the High Court Mr. and Mrs A Leuw sued Mr. W A Bulleid for damages for an injury occasioned by the drill used by him in preparing one of her teeth coming in contact with the floor of her mouth. Severe hæmorrhage took place, and questions arose at the trial, not only with regard to the manner in which the accident was brought about, but also with regard to the subsequent treatment of the wound In the end Mr Justice Bailhache awarded damages to the plaintiff, with regard to the question of negligence, on the ground that either the defendant allowed the carborundum wheel to slip, in which case he would be liable, or that, assuming that the patient caused the accident by swallowing while the wheel was being used, the defendant ought to have warned her not to do so, or requested her to notify him before doing so unless he could control her tongue in any case with the mirror. The accident, it may be observed, is one to which any dentist might at some time or other be liable, and the judge said expressly, in giving judgment, that although the evidence constrained him to find that there was "negligence," it implied nothing against the defendant's professional skill, or that there was more than a momentary lapse from caution on his part. Dr. Hugh Woods has since written, as secretary of the London and Counties Medical Protection Society, to point out, with justice, that extreme rarity in the occurrence of an accident is no proof that when it does occur it was the result of negligence.

A point of some interest with regard to medical witnesses was raised, however, in the course of the case by Sir Herbert Waterhouse, who was called on behalf of the plaintiffs, having been consulted by Mrs. Leuw four days after the accident took place. Sir Herbert Waterhouse explained to the judge that he had been summoned to give evidence under a subpœna, and submitted that in the circumstances he had the right to restrict his evidence to facts observed by him and to refuse to answer any questions intended to elicit from him an expert opinion as to the treatment of the plaintiff by the defendant. The judge expressed his appreciation of the point raised, but it is to be observed from the report of his evidence that Sir Herbert Waterhouse did, in fact, express certain opinions as to the probable nature of the wound and as to what was said to have been done to arrest the hæmorrhage. The question suggested would appear to be, "Can a witness, a medical man who has observed certain conditions in a patient and has been subpœnaed to attend at a trial and to give evidence with regard to them, be compelled further to express opinions as an expert upon matters not within his actual experience affecting his patient's condition?" In other words, in a case such as the one under discussion, having entered the witness-box in obedience to a subpœna, can he be obliged to criticise the treatment given by another practitioner? He might, no doubt, be very glad to refuse, and it would be convenient if it were recognised by the court that he was at liberty to do so. We doubt, however, whether the witness in the circumstances indicated can do more than Sir Herbert Waterhouse did—namely, protest, leaving the judge to make any comment that the occasion, in his lordship's opinion, may demand. We do not find any precedent for a witness on subpœna being regarded as distinct from other witnesses. The question whether a witness is one who can rightly be asked to express an opinion is always one for the judge. A witness in the position in which Sir Herbert Waterhouse was placed can explain, if he feels that he ought to do so, that he has not had such an opportunity to become acquainted with the facts as would qualify him to express an authoritative opinion upon them. The judge would, no doubt, give weight to an objection so raised; but we doubt if such a witness can have any right or privilege of refusing his evidence at his own option. It may, however, be pointed out that the occasion is not likely often to arise. With expert witnesses of other kinds it is likely to do so very seldom. With them and with medical men an obvious observation would apply. Expert witnesses are called to support the side which calls them, and are usually prepared to do so, having carefully studied the facts which others will prove. Counsel do not ask questions, particularly of their own witnesses, by whose answers they are bound, unless they are pretty sure of the nature of the answer that will follow. A prudent man, to use an advocate's phrase, does not fire off his gun unless he knows how it is loaded. Consequently, a medical practitioner who has kept strictly to himself his opinions on a given subject is not likely to be asked for them in the witness-box or to be pressed to give them if he shows himself reluctant in doing so. It must be remembered that we are here speaking of a witness who has attended unwillingly in obedience to a subpœna, and of his evidence in chief. In cross-examination he would be liable to be asked for opinions if it were believed that the replies would be favourable to the side putting the questions.

CONTROL OF VENEREAL DISEASE.

The Increase in Ophthalmia Neonatorum and its Significance.

THE significance of the increase in the notifications for ophthalmia neonatorum cannot be overlooked. In 1918 the total number of cases notified was 6532, in 1919 it was 8548. Taking the figures for successive quarters of the year 1919—namely, first quarter 1413, second 2036, third 2353, fourth 2746—we note a steady increase during the year. We may well ask whether maternal gonorrhœa has increased in this proportion. It would be enlightening to discover how many of these mothers were under treatment for gonorrhœa before the birth of their children and whether they were known to be infected or not. When these facts are known, it still remains to inquire if the simple precautions necessary to safeguard the infant's eyes at the time of birth were taken, and if not why not.

The Manchester Early Treatment Centre.

The report of Dr. W. A. Young, assistant M.O.H. for Manchester, on the result of the first three months' work of the Venereal Disease Early Treatment Centre for males in that city is of considerable interest. During that period 1016 attendances were registered, 708 persons received treatment and 117 were referred to different clinics in the city. At first, treatment was given to every individual who applied for it within two days after exposure to risk, but those applying late were warned that treatment could not be relied upon to prevent, after so long a period had elapsed. From Jan. 5th onwards no treatment was administered when more than 24 hours had elapsed from the risk of infection. Later it was laid down that no treatment would be given after an interval of 12 hours. One point already brought out is this: there seems no reason for believing that individuals have, to any marked extent, been instigated to take fresh risks, inasmuch as there have only been two instances of habitual frequenters of the centre. We hope that the Ministry of Health will consent to the request for this centre to continue its work, and will give the desired permission for another to be opened. The cost per head has worked out at 2*s*. 0½*d*. Truly this is a small sum when it is realised what the average patient suffering from venereal disease costs the community through loss of work, apart from maintenance in hospitals, asylums, or infirmaries. We reiterate our plea for the establishment of a similar experimental early treatment centre in London.

Report for 1919 on the Treatment of Venereal Diseases in Birmingham.

A report prepared by Dr. J. Robertson, M.O.H. for Birmingham, shows a considerable increase during the year 1919 in the number of venereal cases coming for treatment. It is difficult to say whether the maximum has now been reached, but there is some suggestion that it was reached during the third quarter. As regards gonorrhœa, there were during the year 1399 new male cases and 187 female cases, as compared with 685 and 118 during 1918. The total number of attendances were 11,925 for males and 1531 for females. For syphilis the new cases were 782 males and 459 females, as compared with 603 and 41 for 1918. The total attendances were 10,433 for males and 6881 for females; 8373 doses of salvarsan substitutes were given. The figures for gonorrhœa suggest that the number of cases coming for treatment are not as numerous as they should be, especially in the cases of females. An unsatisfactory feature is that nearly one-half the patients cease attendance before the completion of treatment. The present facilities provided are: (*a*) for males, five clinics weekly, staffed by nine medical officers at the General Hospital, and two evening clinics at the Skin and Urinary Hospital, staffed by two medical officers. In addition, attendances are made at other times for injections and irrigations. A whole-time orderly is present at each centre. (*b*) For females, the General Hospital provides three clinics weekly, staffed by two medical officers, the Skin and Urinary Hospital provides one evening clinic, and the Women's Hospital one clinic. During the year 1300 enamelled iron notices have been fixed in factories and other places detailing the facilities offered. The total cost of the venereal diseases scheme during 1919, including the expenses of clinics, pathological laboratories, and publicity, amounted to £8573.

Continuous Mercurial Treatment.

The *Bulletin de la Société Française de Dermatologie et de Syphiligraphie*, No. 2 (1920), publishes a communication by Dr. Ch. Abadie on the Action of Uninterrupted and Prolonged Mercurial Injections in the Treatment of Certain Manifestations of Syphilis. Dr. Abadie recommends the employment of intravenous injections of cyanide of mercury in doses of a centigramme three times a week. He insists on the importance of continuing this treatment without interruption over a period of three to six months. Whatever may be the theoretical arguments in favour of allowing periods of rest, Dr. Abadie considers that in actual practice better results are obtained by carrying on continuous treatment. The cases under his care have been mainly cases of ocular syphilis, such as chorio-retinitis. In many apparently hopeless cases marked improvement resulted from the adoption of prolonged and uninterrupted treatment with cyanide of mercury. He recommends the employment of this method in other rebellious forms of syphilis, such as leucoplakia, cardiac syphilis, and the dystrophies and spastic paralysis of childhood.

Expert Examination in Law Suits.

In view of the greatly increased attention which is being devoted to the medical and sociological aspects of venereal disease it is reasonable to imagine that the question of infection will be much more prominently brought forward in the divorce and other courts than has hitherto been the case. This would be so even if legislation remained as it is at present, but, in view of the new legal measures which are sure to be brought into force by the pressure of public opinion, the definite diagnosis of venereal disease will become of even greater evidential value. We would here call attention to a position which, unless it is largely modified, will tend seriously to interfere with the course of justice. Imagine the case of a man or woman seeking judicial assistance, whether it be for divorce, separation, or other form of redress, on the plea that his or her partner is suffering from venereal disease. As matters are at present the defendant might bring evidence from two or three medical men to the effect that he or she had been examined by them and found to be free from the disease in question. The signatories to this evidence need not necessarily be venerologists, and even if they were there is no certitude that the examination upon which their evidence is based would necessarily be of the most searching nature. Owing, therefore, to inefficient examination a serious miscarriage of justice might ensue. We hold that in the interest of the community the court should be able to order all such cases to be examined by a venerologist selected for the purpose. Should the present arrangement continue the ends of justice will necessarily be frustrated.

Royal Free Hospital Post-graduate Course.

A course has been arranged by the London (Royal Free Hospital) School of Medicine for Women, the Royal Free Hospital, the Elizabeth Garrett Anderson Hospital, and the London Lock Hospital for the instruction of qualified medical women in the treatment of venereal diseases. The course will begin on Monday, May 17th, at 5 P.M., and conclude on Saturday, May 29th. The course will include out-patient clinics for women and children by Dr. Margaret Rorke, Dr. Naomi Tribe, Mr. J. E. Lane, and Mr. J. J. Abraham; demonstrations by Mr. Charles Gibbs and Dr. Elizabeth Lepper; visits to maternity wards and labour department under Dr. Morna Rawlins; and lectures by Mr. Lane and Mr. J. E. R. McDonagh. Qualified medical women should send in their names to Miss Louie M. Brooks, warden and secretary of the Medical School. Fee for the whole course, £5 5s. The library, refectory, and common rooms at the Medical School are available for use by the post-graduate students attending the course. The course will be repeated during the second fortnight of September.

"How Not to Do It."

In a pamphlet on "Venereal Diseases and their Treatment—How Not to Do It," just issued by the National Association of Medical Herbalists of Great Britain, an outline is given of the "orthodox treatment of venereal diseases," which is stated to nullify "the claim of the regular profession to any special knowledge of their origin and nature, or to any infallible remedy for their cure." The conclusion is drawn that "the Government are not justified in subsidising the arsenical and mercurial remedies which are favoured for the time being by the regular profession, and still less are they justified in seeking to suppress all unorthodox methods of treatment."

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

General Nursing Council for Scotland.

THE appointment of the members of the General Nursing Council for Scotland, established by the Nurses Registration (Scotland) Act, 1919, has now been completed. The general composition of this Council was described in your issue of Jan. 24th (p. 226). The following is a list of the members of the Council:—

Appointed by the Privy Council: Captain Charles B. Balfour, C.B., Lord Lieutenant of the County of Berwick.

Appointed by the Scottish Education Department: Miss Norah Milnes, B.Sc., Director of the School of Social Study and Training, Edinburgh University.

Appointed by the Scottish Board of Health: Dr. A. K. Chalmers, Medical Officer of Health, Glasgow; Dr. Katherine Clark, Assistant Medical Officer to the Edinburgh Education Authority; Dr. H. E. Fraser, Medical Superintendent, Royal Infirmary, Dundee; Colonel D. J. Mackintosh, C.B., M.V.O., Superintendent, Western Infirmary, Glasgow; Miss Margaret Bell, Queen's Nurse, Musselburgh; Miss Kathleen L. Burleigh, Matron, Royal Hospital for Sick Children, Edinburgh; Miss Annie Gill, R.R.C., Lady Superintendent of Nurses, Royal Infirmary, Edinburgh; Miss Mary Hunter, Public Health Department, Glasgow; Miss Elizabeth T. Jones, School Nurse, Edinburgh Education Authority; Miss Janet Melrose, R.R.C., Matron, Royal Infirmary, Glasgow; Miss Florence A. Merchant, Matron, Stobhill Hospital, Glasgow; Mr. T. Prentice, Mental Hospital, Hartwood, Lanarkshire; Miss Margaret R. Stewart, Secretary and Treasurer, Scottish Nurses' Club.

Arrangements will be made by the Scottish Board of Health for convening the first meeting of the Council at an early date.

University of Glasgow: Faulds Fellowships.

Under the bequest of the late William Brechin Faulds, writer in Glasgow, four Faulds Fellowships have been instituted in the Faculties of Arts, Medicine, Divinity, and Law respectively. Each Fellowship is tenable for three years, subject to the fulfilment of the prescribed conditions. The stipend of each Fellow in any year will be one-fourth of the net annual income of the trust fund for the preceding year, and the Fellowship will be awarded by the Senatus, on the recommendation of the Faculty concerned, and will not be tenable along with any other graduate Fellowship or Scholarship. Candidates in Medicine must be men who have within the three academical years immediately preceding the award completed the medical curriculum by passing the Final Professional Examination required for graduation, and taken the degrees of M.B., Ch.B. The applications of candidates in each Faculty will be considered by that Faculty, who will take into account the candidates' general academic record, the evidence of their capacity for advanced study, inquiry, or research, and the results of any independent work, published or unpublished, which they may have undertaken, arranging for such trial and oral or practical examination as may be deemed necessary for their decision. During the tenure of his Fellowship the Fellow must devote himself to some branch of advanced study, inquiry, or research recommended by his Faculty and approved by the

Senatus, and arrangements are provided for report to the Faculty on his progress.

The Glasgow Post-graduate Medical Association.

At a recent joint meeting of the Faculty of Medicine of the University of Glasgow and the General Committee for Post-graduate Teaching, a comprehensive scheme for permanent post-graduate medical teaching in Glasgow was adopted. The joint committee recommend the formation of a central organisation, to be known as the Glasgow Post-graduate Medical Association, for arranging, coördinating, and administering the teaching in Glasgow and the West of Scotland. The Board of the Association is to consist of representatives of those teaching institutions which grant facilities for post-graduate teaching, and of the teachers themselves. The joint committee also issue certain suggestions for the organisation of the courses. These are to include "refresher" courses of four to six weeks' duration for the general practitioner, to be held twice a year; weekly demonstrations for the benefit of local practitioners; and advanced and comprehensive full-time courses of six months' duration, leading to a diploma, on subjects such as obstetrics and child welfare, school medical inspection, hygiene, tuberculosis, and venereal diseases. It is emphasised that the future development of the scheme depends largely on financial considerations and the possibility of obtaining some assistance from the Government.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Hunger Strike in Mountjoy Prison.

THE hunger strike of some 89 prisoners in Mountjoy Prison, Dublin, last week, in order to obtain recognition of status as political prisoners, placed the medical officers of the prison in as difficult a position as any in which a medical man can find himself. To have the care of so many men gradually losing their hold on life and to be able to do next to nothing to prevent it—for forcible feeding is no longer permitted—is very trying for a humane member of our profession. The final decision of the Government to release any prisoners who, in the opinion of the medical officers of the prison, were in danger of death, came in time to prevent any calamity. It is not surprising to learn that prior to this one medical officer felt himself compelled to resign his post, and the health of the other was so injured by the strain that he was subsequently rendered unfit for duty. The humanity of the medical officers was recognised by the friends of the prisoners, many of whom mentioned it specially in conversations which have since been published.

Ulster Medical Society.

At the ninth meeting of session 1919–20 of the Ulster Medical Society, held on April 16th in the Belfast Medical Institute, Mr. A. Fullerton being in the chair, Dr. H. F. Lechmere Taylor (Edinburgh) and Dr. E. Montgomery (Belfast) gave an account of medical work in India. The main features in connexion with the hospital which they described were the infrequency of appendicitis and malignant disease, as well as of abdominal tumours; and the frequency of stone, malaria, and cataract.

The Water-supply of Belfast.

The water in store on April 8th was (as reported at the fortnightly meeting of the Belfast Water Commissioners held on April 16th) 2770 million gallons, while on the same date in 1919 it was 2787 million gallons. The estimated population at present being supplied was 443,492, and the daily consumption averaged 17,610,000 gallons, which equalled 39·69 gallons per head of the population, a larger amount than formerly—that is, since the war. The matter is one, of course, of urgent medical interest to us in Belfast.

The Queen's University of Belfast.

At a meeting of the Senate of the Queen's University of Belfast held on April 15th it was announced that Mr. F. A. Heron, of Maryfield, near Belfast, proposes to give the University a gift of £5000, to be applied exclusively for the teaching of physical chemistry. The Vice-Chancellor having spoken of the great need of further equipment in the faculties of medicine and science, Lady Pirrie, in supporting him, said the Royal Victoria Hospital and the University were complementary to each other in their work, and she hoped the Vice-Chancellor would assist in getting further subscriptions for the hospital to meet its ever-increasing needs.

Poor-law Doctors' Salaries.

On April 17th a joint application was presented to the Omagh board of guardians for an increase of salary on the part of the medical Poor-law officers of Cavan, Donegal, Fermanagh, Monaghan, and Tyrone. The application urged that the salaries of dispensary doctors should be fixed at £300 per annum, rising annually by £5 to £400, with £50 yearly as medical officer of health; that the salaries of workhouse medical officers should be £200 yearly, rising annually by £5 to reach £300; that locum-tenents be appointed at £7 7*s.* weekly for dispensary districts, and £5 5*s.* for workhouse hospitals, or, where both duties are combined, that the payment should be £10 10*s.* a week; and that one month's leave be granted to medical officers annually. There was prolonged silence, I understand, after the above application was read, a member of the Omagh board of guardians remarking "that it had struck the members speechless." The board adjourned the question indefinitely, a member stating that the farmers would be bankrupt "if this goes on." It is generally believed that no people in Ireland have, since the beginning of the war, done better than the farmers.

April 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

New Regulations for the Sale of Poisons.

THE increase in drug-taking and the abuse of hypnotics have led to more stringent laws controlling the sale of these substances. The law of July 12th, 1916, and the decree of Sept. 14th, 1916, have forbidden the chemist to sell to the same person a quantity to last more than seven days of any poisonous substance named on the official list. After this time the patient has to present a new prescription. The chemist who renews an old prescription lays himself open to a fine of 1000 to 10,000 francs, to a term of imprisonment from three months to two years, and to the erasion of his name from the register. Also, prescriptions ordering quantities of poisons for more than 20 days of treatment have to be refused. These rules are obviously inspired by the desire to combat the illicit traffic in opium, morphia, and cocaine, but they are also applicable to other poisons on the official list, including, for example, mercurial salts. Now these are used for prolonged treatment in cases where it is impossible to ask the patient to return every week to his doctor or hospital for a new prescription. Such cases include women who have been ordered perchloride douches for vaginal discharges, and syphilitics who are being treated by mercury in the form of pills, taken twice daily in series of 40, with monthly and later two-monthly remissions, for three or four years. This method of treatment still has many adherents among those suspicious of the uncertain action of arsenobenzol and of the special conditions of its administration. The Société Médicale de l'Est, following a most careful report by M. Perrin, points out that the difficulties thus introduced by the law will encourage still further the tendency of the syphilitic to neglect his treatment, and will hinder the fight against venereal diseases. This society has decided to press for the modification of the law on this point.

The Effects of the Paper Crisis.

The paper crisis may lead to the suspension of the medical periodicals, already sorely tried by the printers' strike last month. The difficulty cannot be overcome by raising the price to subscribers and the tariff of advertisements. Scarcity and high price of paper are also impeding the publication of books, and in this way menacing scientific progress. Among the remedies proposed one is the suppression of the thesis required for obtaining the degree of doctor of medicine. This formality dates back four centuries at least. At first the thesis was only a big sheet of paper surrounded by symbolic engravings, on which a candidate had printed the various propositions he wished to submit to his judges. Little by little the thesis became a scientific memorandum on a subject chosen by the candidate and on which he was prepared to defend his conclusions. The number of copies that had to be furnished steadily rose. Every university library in France required one to enrich its collection, and foreign universities followed offering theses of their own in exchange. The hundred copies of the theses now obligatory, at the present cost of paper and printing, makes a heavy tax on the resources of the young student. It is proposed, therefore, to suppress this formality. Those in favour of abolition point out that the majority of theses are valueless compilations made with the help of fellow students. A candidate who has the money may even buy a ready made thesis from some impecunious but better informed comrade. The few communications of real value might be brought to notice at learned societies or by publication in the journals. Instead of the prizes given every year for the best theses, consisting in medals and possibly the remission of some of the high examination fees, it is suggested that the same result could be obtained by offering a substantial reward for valuable articles published, a procedure which would also ensure the interests of scientific progress. For the immense majority of candidates who have no ambition beyond becoming general practitioners the heavy pecuniary burden of the thesis has no compensation, while their diligent but mediocre screeds encumber the shelves of the professors who are entitled to receive reprints—until they are sold by the housekeepers as waste paper. Besides this there are the essays puffing proprietary articles of which the manufacturer pays the cost of production, or those by which the young doctor seeks to establish himself in practice. The time is opportune to make a clean sweep of this mediæval custom.

Living Micro Organisms in Papyrus and Amber.

In a recent remarkable communication to the Academy of Medicine, Dr. Galippe announced his discovery in an Egyptian papyrus of microscopical organisms capable of motion and reproduction. These microbes were contained in the very fibres of vegetable matter which served in the manufacture of the papyrus. More recent researches by the same observer carry us back still further. This time the centre of interest is the fossil resin, popularly known as amber, to be found thinly distributed in cretaceous strata. The period of its formation is so remote that competent geologists hesitate to give a precise date even in millennia. But in spite of this, the resin was found to contain living atoms contemporaneous with its formation. By special processes Dr. Galippe convinced himself of his ability to reawaken them, like the sleeping princess of the fairy story, from their long slumber. They then showed active movements and power to reproduce themselves. This quasi indestructibility of the infinitely small, its resistance to the action of time and of physical and chemical agents, is a biological property of fascinating interest—but its existence is challenged.

April 19th.

THE NURSES' COOPERATION.—This organisation, which has for its main object the securing of full remuneration to nurses for their work, shows by its annual report for 1919 a successful year of operation. The fees received by the nurses have exceeded those earned in any previous year—namely, £61,059, or £3774 more than last year. Beginning in 1891 with a staff of 30 nurses, the coöperation has now 442 fully trained nurses on the general staff and 36 asylum trained nurses for mental patients. The total number of cases nursed in 1919 was 6169, or 114 more than in the previous year. The address of the coöperation is 22, Langham street, Portland place, London.

URBAN VITAL STATISTICS

(Week ended April 17th, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality which had been 18·7, 16·7, and 16·6 in the three preceding weeks, further declined to 15·8 per 1000. In London with a population of nearly 4¼ million persons, the annual death rate was 16·1, or 1·5 per 1000 below that recorded in the previous week, while among the remaining towns the rates ranged from 5·4 in Enfield, 7·2 in Oxford, and 8·0 in Reading, to 25·2 in Blackburn, 26·5 in Sunderland, and 32·4 in Tynemouth. The principal epidemic diseases caused 411 deaths, which corresponded to an annual rate of 1·2 per 1000, and included 185 from measles, 102 from whooping cough, 53 from infantile diarrhœa, 51 from diphtheria, 15 from scarlet fever, 3 from enteric fever, and 2 from small pox. Measles caused a death rate of 2·0 in Bootle, 2·1 in Wakefield, 2·4 in Brighton and 4·8 in Newport (Mon.). The fatal cases of small pox belonged to West Ham and Liverpool respectively. The deaths from influenza, which had been 392, 379, and 332 in the three preceding weeks further declined to 306, and included 101 in London, 22 in Birmingham, 12 each in Manchester and West Ham, and 10 in Blackburn. There were 1960 cases of diphtheria, 1902 of scarlet fever, and 24 of small pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1995, 2011, and 26 respectively at the end of the previous week. The causes of 42 of the 5379 deaths in the 96 towns were uncertified, of which 6 were registered in Birmingham, 5 in Liverpool, and 4 each in St. Helens and Manchester.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2¼ million persons the annual rate of mortality, which had been 18·0, 17·2, and 17·3 in the three preceding weeks, rose to 18·9 per 1000. The 414 deaths in Glasgow corresponded to an annual rate of 19·4 per 1000, and included 29 from influenza, 25 from measles, 5 from diphtheria, 2 each from enteric fever, scarlet fever and whooping cough, and 1 from infantile diarrhœa. The 108 deaths in Edinburgh were equal to a rate of 16·5 per 1000 and included 8 from influenza and 1 each from measles and diphtheria.

Irish Towns.—The 251 deaths in Dublin corresponded to an annual rate of 31·5, or 4·7 per 1000 above that recorded in the previous week, and included 16 from whooping cough, 15 from measles, 5 from influenza, 2 from infantile diarrhœa, and 1 each from scarlet fever and diphtheria. The 229 deaths in Belfast were equal to a rate of 28·9 per 1000, and included 17 from influenza, 6 from whooping cough, 5 from measles, 2 from infantile diarrhœa, and 1 from scarlet fever.

VITAL STATISTICS OF LONDON DURING MARCH, 1920

IN the accompanying table will be found summarised statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious disease, it appears that the number of persons reported to be suffering from one or other of the ten diseases notified in the table was equal to an annual rate of 7·1 per 1000 of the population, estimated at 4,358,309 persons; in the three preceding months the rates had been 9·9, 8·5, and 7·7 per 1000. Among the metropolitan boroughs the lowest rates from these diseases were recorded in Hammersmith, the City of Westminster, St. Marylebone, Hampstead, Islington, Stepney, and Bermondsey; and the highest in Fulham, Finsbury, Bethnal Green, Battersea, Deptford, and Lewisham. Eleven cases of small pox were notified during the five weeks ended April 3rd; of these, 8 belonged to Poplar, 2 to Stepney, and 1 to Woolwich. The prevalence of scarlet fever was 12 per cent. less than in February; this disease was proportionally most prevalent in Chelsea, Holborn, Finsbury, Bethnal Green, Poplar, Deptford, and Lewisham. The Metropolitan Asylums Hospitals contained 1981 scarlet fever patients at the end of the month, against 2841, 2476, and 2266 at the end of the three preceding months; the weekly admissions averaged 240, against 350, 280, and 279 in the three preceding months. Diphtheria was slightly less prevalent than in the preceding month; this disease was proportionally most prevalent in Fulham, St. Pancras, Hackney, the City of London, Shoreditch, Bethnal Green, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1845, 1971 and 2003 at the end of the three preceding months, numbered 1964 at the end of March; the weekly admissions averaged 260, against 239, 263, and 240 in the three preceding months. The prevalence of enteric fever was about equal to that in the two preceding months; of the 59 cases notified during the month 7 belonged to Fulham, 7 to St. Marylebone, 7 to Hampstead, 5 to Deptford, 4 to Paddington, 4 to

* Including membranous croup.

Kensington, and 4 to Battersea. There were 38 cases of enteric fever under treatment in the metropolitan asylums at the end of the month, against 25, 25, and 30 at the end of the three preceding months; the weekly admissions averaged 6, against 2, 4, and 6 in the three preceding months. Erysipelas was proportionally most prevalent in Paddington, Fulham, Stoke Newington, Finsbury, Southwark, and Battersea. The 45 cases of puerperal fever included 5 in Fulham, 5 in Hackney, 4 in Wandsworth, and 3 each in Hammersmith, Islington, Southwark, Battersea, and Camberwell. The 22 cases of cerebro-spinal meningitis included 4 in Hackney, 3 in Islington, 3 in Wandsworth, 2 in Battersea, and 2 in Lewisham; while the 2 cases of poliomyelitis belonged respectively to Hammersmith and Battersea.

The mortality statistics in the table relate to the deaths of civilians actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the five weeks ended April 3rd the deaths of 7350 London residents were registered, equal to an annual rate of 17·6 per 1000; in the three preceding months the rates had been 13·1, 14·6, and 16·6 per 1000. The death-rates ranged last month from 12·3 in Wandsworth, 12·7 in Hampstead, 12·8 in Lewisham, 13·1 in Woolwich, 14·6 in Paddington, 14·6 in Fulham, and 14·7 in Hammersmith, to 20·5 in Finsbury, 20·7 in Bermondsey, 21·4 in Shoreditch, 21·7 in Hackney, 22·9 in Poplar, 23·4 in Stepney, and 25·7 in Bethnal Green. The 7350 deaths from all causes included 716, which were referred to the principal infectious diseases; of these, 2 resulted from small-pox, 295 from measles, 24 from scarlet fever, 137 from diphtheria, 181 from whooping-cough, 3 from enteric fever, and 74 from diarrhœa and enteritis among children under 2 years of age. No death from any of these diseases was recorded last month in the City of London. Among the metropolitan boroughs the lowest death-rates from these diseases were recorded in Paddington, Hammersmith, Chelsea, the City of Westminster, Hampstead, and Holborn; and the highest in Hackney, Shoreditch, Bethnal Green, Poplar, and Bermondsey. The 2 fatal cases of small-pox belonged to Poplar. The 295 deaths from measles were 9 fewer than the average number in the corresponding period of the five preceding years; this disease was proportionally most fatal in Islington, Hackney, Bethnal Green, Southwark, and Bermondsey. The 24 fatal cases of scarlet fever exceeded the average by 6, and included 3 in Camberwell and 2 each in Shoreditch, Bethnal Green, Stepney, Bermondsey, and Lambeth. The 137 deaths from diphtheria were nearly double the average; the greatest proportional mortality from this disease occurred in Hackney, Finsbury, Bethnal Green, Southwark, Lambeth, and Battersea. The 181 fatal cases of whooping-cough were 22 in excess of the average; this disease was proportionally most fatal in St. Pancras, Stoke Newington, Hackney, Bethnal Green, Stepney, Poplar, and Greenwich. Three deaths from enteric fever were registered during the month, against an average of 8; these deaths belonged respectively to Kensington, Fulham, and the City of Westminster. The 74 fatal cases of infantile diarrhœa were 3 below the average; the greatest proportional mortality from this disease occurred in Paddington, St. Marylebone, Shoreditch, Bethnal Green, Camberwell, and Deptford. In conclusion, it may be stated that the aggregate mortality in London during March from these principal infectious diseases was 12 per cent. above the average in the corresponding period of the five preceding years.

DINNER OF THE HARROGATE MEDICAL SOCIETY.—The annual dinner of the Harrogate Medical Society, the first held since the war, took place at the Prospect Hotel, Harrogate, on April 15th, about 70 medical men being present. Dr. W. Bertram Watson, President of the Society, was in the chair, and the guests included Sir Berkeley Moynihan, Dr. Bedford Pierce (President of the British Medico-Psychological Association), Dr. W. H. Willcox, and the Mayor of Harrogate (Alderman J. Shepherd). Sir Berkeley Moynihan referred to the proposed Institute for Investigation, somewhat on the lines of Duff House, where patients exhibiting early errors of metabolism would find at their disposal the best available pathologist, radiographer, and biochemist. He hoped the scheme would shortly materialise, since team-work was essential to-day, and Harrogate was extraordinarily fortunate in opportunities for research. The President briefly replied, and speeches by Mr. Herbert Frankling, Dr. Pierce, Dr. Willcox, and Dr. David Brown concluded a pleasant evening.

Correspondence.

"Audi alteram partem."

TREATMENT OF BILHARZIA DISEASE.

To the Editor of THE LANCET.

SIR,—May I add one or two remarks to the admirable annotation in your issue of April 17th of Dr. F. G. Cawston's paper on the treatment of 30 cases of bilharzia disease with tartar emetic. Dr. Cawston records two cases in which cough followed the injection of the drug, and although he does not expressly say so I gather that he regarded this phenomenon as an unusual one. In my experience the occurrence of a short bout of coughing coming on towards the completion of the injection is an almost invariable phenomenon. In Dr. Cawston's Case 5 he seems to suggest that the antimony injections were the cause *of a chronic cough persisting for a fortnight and aggravated* by each injection. I can hardly think the persistence of the cough can be ascribed to the antimony, and it would have been extremely interesting if Dr. Cawston had recorded the results of a careful examination of the chest during this period.

With regard to a rise of temperature, with possibly a rigor as a result of tartar emetic injections, my experience coincides with Dr. Cawston's in regarding such occurrences as rare in the treatment of bilharzia disease. In trypanosomiasis, however, marked rise of temperature, together with rigor, is frequently noted as a result of injections of tartar emetic. This I regard, however, as due to a massive trypanolysis, rather than to the action of the drug, as later in the course of the disease, when parasites have become extremely scanty as a result of treatment, rigors or any marked rise of temperature are unusual.

In cases treated by intravenous injections of tartar emetic a marked rise of temperature and rigor may occasionally occur in a patient who has never exhibited this reaction in possibly numerous previous injections. Such a result, as you rightly point out, may be due to some impurity in the distilled water used for the injection. In my experience, where the freshness and purity of the distilled water could be guaranteed, a violent reaction might occasionally occur, and seemed to me to be due to the temperature of the injected solution being introduced at a temperature below blood heat. At any rate, that was the only cause I could assign, and after this was attended to such untoward and unusual effects were eliminated. I may say I always make a practice of administering the dose of tartar emetic in high dilution—i.e., in some four to six ounces of fluid.—I am, Sir, yours faithfully,

H. B. NEWHAM.

London School of Tropical Medicine, Endsleigh-gardens, N.W., April 18th, 1920.

WAR ŒDEMA AND EPIDEMIC DROPSY.

To the Editor of THE LANCET.

SIR,—It will be a pity if, as the outcome of Dr. A. D. Bigland's excellent article on Œdema as a Symptom in So-called Food-Deficiency Diseases in THE LANCET of Jan. 31st, a confusion should arise between famine dropsy and epidemic dropsy. The disease called by Macleod epidemic dropsy, with its itching, burning, and erythema or urticaria which preceded or accompanied the anasarca, was probably ankylostomiasis. This outbreak in Mauritius, described by Macleod, Davidson, and Chevers, and referred to later in Manson's and Daniels's works on tropical diseases, does not bear any real epidemiological resemblance to the famine dropsy so clearly differentiated by Cornish and Porter in the Indian famine of 1877–78. Giles, in his "Report on the Causes of the Diseases Known in Assam as Kala-azar and Beri-beri" (1890), showed these diseases, and, I think, Macleod's "epidemic dropsy," to be ankylostomiasis. Macleod himself directs attention to the relationship between the Mauritius and the Assam cases, and states definitely that "this dropsical disease was by no means confined to the impoverished and sickly." Simultaneously, however, in the Madras famine Cornish and Porter observed and first described clearly "famine dropsy" which, during the war, has been rediscovered under a variety of terms, including "war œdema" and "hunger œdema." Cornish had recognised the disease even earlier, in 1864, when he discussed prison dietaries and diseases. Cornish's references are as follow:—

1. A reply to Sir Richard Temple's minutes of March 7th and 14th, 1877, as to the sufficiency of a pound of grain as the basis of famine wages.
2. Digby: The Famine Campaign in Southern India. Longmans, vol. ii., p. 196, 1878.
3. Cornish: Madras Quarterly Journal of Medical Science, vol. viii., 1865: Observations on the Nature of the Food of the Inhabitants of Southern India and on Prison Dietaries in the Madras Presidency.

Cornish was sanitary commissioner for Madras during the famine of 1877–78. Porter was in charge of a famine relief camp at the same period. He published exact post-mortem findings in his book, "The Diseases of the Madras Famine of 1877–78," by Alexander Porter, M.D., F.R.C.S.I. (Madras Government Press, 1889).

I am, Sir, yours faithfully,

Bristol, April 16th, 1920. J. A. NIXON.

ANÆSTHETISTS' REMUNERATION.

To the Editor of THE LANCET.

SIR,—Since at the present time a greater degree of skill is being demanded on the part of anæsthetists than a few years ago, it is only fair that what then was an adequate remuneration should be correspondingly raised, apart from the question of the higher rate of living, the greater expense of apparatus, anæsthetic drugs, and locomotion. It is, however, necessary to educate the public, and to a lesser extent the general practitioner, to recognise the market value of the skilfully given anæsthetic. Surgeons can help anæsthetists by insisting that the patient should receive a note of fees from the anæsthetist himself, by telling the patient beforehand the amount of such fee, and by not accepting an inclusive fee as is so often done. In this way the anæsthetist would soon cease to be regarded merely as the appanage of the surgeon.

Some years ago in America I was informed that a skilful anæsthetist expected a fee corresponding to 25 per cent. of that of the surgeon. It is only within the last few years that a 10 per cent. ratio has come into force in this country. It does not seem a fair thing for a surgeon who is asked to reduce his fee, say, from 100 guineas to 50 guineas to expect his anæsthetist to reduce his from 10 guineas to 5 guineas, unless the ratio is considerably higher than at present; and I think very few surgeons would object to anæsthetists' fees being raised to a sum corresponding to 20 per cent. of that of the surgeon's fee with a minimum of 5 guineas. I am, Sir, yours faithfully,

HUGH R. PHILLIPS, M.D.

Cavendish-court, Cavendish-square, W., April 17th, 1920.

THE FEDERATION OF MEDICAL AND ALLIED SOCIETIES.

To the Editor of THE LANCET.

SIR,—Recent events have emphasised the urgent necessity of providing more adequate means for the collective expression of medical opinion in the councils of the nation, and, if public sympathy is not to be alienated from our cause, we must ensure that the means adopted are compatible with the dignity of our profession. The manifest unfairness of much of the public treatment meted out to us as a profession has largely, if not entirely, resulted from the failure of our various organisations to coöperate in giving expression to their views in the guidance of public opinion and in assisting to frame legislation on health matters. Whilst fully appreciating the great services many of these organisations have rendered, one has to recognise that they are only able to represent the views of their members and that coöperation would tend greatly to increase their value to the profession and to the community in general. Hitherto a few of the bodies have coöperated in times of emergency, but there has never been available a permanent conference table to which the public and the Government could turn for a united opinion on matters of national health.

This need for a central representative body, in which all branches of medical and allied practice can coöperate, has been met by the Federation of Medical and Allied Societies which has already secured the support of some 40 organisations, varying in influence from the Royal Society of Medicine to the smaller provincial medical societies, and in addition provides the coöperation of all the allied professions, as represented by the British Dental Association, the College of Nursing, Royal British Nurses' Association, Pharmaceutical Society of Great Britain, Incorporated Midwives' Institute, and other bodies. Each of these organisations has representation in the Federation in accordance with its membership and retains inviolate its individuality, freedom of action, and right to express its views separately or collectively as may seem expedient.

The Federation has already been privileged to render service in linking up existing bodies, and in voicing their demand for a public inquiry into the conditions of medical service under the Insurance Acts. Its utility is much increased by the fact that seven medical Members of Parliament have seats on its Council and, as its position becomes stronger, it will be able to render increasing assistance to medical candidates, irrespective of party, and thus materially help in increasing medical representation in the House of Commons.

The Council of the Federation is now able to give effect to one of the original terms of its reference by admitting as individual Associates members of the medical and dental professions. Circulars are being sent out inviting applications for such membership, at an inclusive subscription of half a guinea, and it is hoped that all medical men will contribute the small sum asked and take an active part in ensuring the permanent success of a movement which provides practical means for the collective expression of medical opinion in guiding legislation through the difficulties inseparable from the reconstruction of the health services of the country.

I am, Sir, yours faithfully,
N. HOWARD MUMMERY,
General Secretary, the Federation of Medical and Allied Societies.
5, Vere-street, Cavendish-square, London, W.1,
April 14th, 1920.

LIFE ASSURANCE AND GLYCOSURIA.

To the Editor of THE LANCET.

SIR,—I have read with interest the expected criticism of my article, and am glad to learn the valuable opinions of your correspondents. So long as assurance companies desire that no information should be given to the proposer in any case of the result of the medical examination, it is the duty of the medical officer to observe this rule, and I follow it myself in all cases. My remarks on this point referred to one class of cases only—glycosuria, often intermittent or temporary. In these cases, after the medical examination, the proposer is informed by the assurance company that he is rejected. If the reason is asked the reply is, "On account of sugar in the urine" (or urinary change). He may at once conclude he is suffering from severe diabetes and be greatly shocked, or he may be angry and, feeling no disability, take no further heed to his condition; but usually he consults his medical attendant (and this will be at least a few days after the examination), and when the urine is again tested it may be quite free from sugar. And here the trouble arises. The proposer concludes that a mistake must have been made at one of the examinations. He consults other medical men, who may also find the urine quite normal, and he concludes he has been unfairly treated and disputes occur. Having been often requested to help to settle such disputes, it still appears to me desirable that some other course of procedure should be followed than that usually adopted.

In my article the various tests for glucose were not the subject of consideration. I spoke of Fehling's solution or some of its modifications. Many of the modifications are much superior to Fehling's solution (Benedict's is one of them) and are preferable. The phenyl-hydrazin test and the fermentation test are of much service, since negative results would show that the reducing substance in the urine was not glucose; but many other tests would be required to determine what the reducing body was; and, of course, if these two tests give positive results, other tests are required to distinguish between glucose and lævulose, maltose, &c. I have found blood examinations of much interest, and am glad to note the value attached to them by many writers in the last five years; but it would not be practicable to require them frequently in examinations for life assurance.—I am, Sir, yours faithfully,

Manchester, April 17th, 1920. R. T. WILLIAMSON.

BLIND MASSEURS.

To the Editor of THE LANCET.

SIR,—Will you allow me to draw the attention of your readers to the fact that at the recent examinations of the Incorporated Society of Trained Masseurs, which are known throughout the world for their completeness, Corporal Herbert Vickers, a blinded soldier of St. Dunstan's, passed first in all subjects. That this was no mean accomplishment may be judged by the fact that there were nearly 300 entrants for this examination. Of these less than 50 per cent. passed; while of the 16 St. Dunstan's entrants, of whom Corporal Vickers was one, 15 passed, and the one failure was accounted for by the fact that the unsuccessful candidate had for some weeks before the examination suffered severely from neuralgia, which had almost entirely robbed him of sleep.

I am, Sir, yours faithfully,
ARTHUR PEARSON,
Chairman, Blinded Soldiers' and Sailors' Care Committee
St. Dunstan's, Hanover Gate, Regent's Park, N.W.,
April 16th, 1920.

SIR PATRICK DUN'S HOSPITAL, DUBLIN: WAR MEMORIAL.

To the Editor of THE LANCET.

SIR,—The memorial brass and bed to 30 old Dun's students who fell or died on active service, which has been subscribed for by their comrades who also served in the war, is now approaching completion. A circular was sent to 415 old Dun's men who were on active service concerning this memorial, but it may not have reached some. Any who may wish to subscribe will kindly communicate at once with me at the hospital.

I am, Sir, yours faithfully,
HENRY C. DRURY,
April 20th, 1920. Hon. Sec., Sir Patrick Dun's Hospital, Dublin.

POST-GRADUATE COURSE ON SPA TREATMENT.—It is proposed to hold a post-graduate course from June 7th to 19th, on Spa Treatment in Bath, in conjunction with the Fellowship of Medicine and Post-Graduate Association. An admirable programme has been arranged and may be obtained from Dr. R. G. Gordon, of 6, Queen-square, Bath, secretary of the local committee. It includes morning clinical lectures on gout, arthritis of diverse ætiology, sciatica, fibrositis, and mere general disease, by Drs. R. L. J. Llewellyn, F. G. Thomson, King Martyn, R. Waterhouse, J. Lindsay, and R. G. Gordon. Part of the mornings will be absorbed by visits to hospital wards. In the early afternoons visits will be made to bathing establishments and the apparatus of balneotherapy will be demonstrated. At 5 P.M. lectures on subjects in relation to spa treatment will be given, including one on re-education by Dr. Gordon, one on diet by Dr. Wilson Smith, and one on the contra-indications and limitations of spa treatment by Dr. Llewellyn.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS

Medical Men and the Budget

THE Budget as explained by the Chancellor of the Exchequer to the House of Commons on Monday, April 19th, contains several important changes in taxation The standard rate of income-tax is unchanged, but new schedules are set out giving effect to the recommendations of the recent Report of the Royal Commission on Income tax and Super tax An entirely new system of graduation is adopted The duties on spirits are increased from 50*s* to 72*s* 6*d* per proof gallon, and the beer duty is raised from 70 to 100*s* per standard barrel Mr CHAMBERLAIN stated that he proposes to continue the existing motor car taxes and motor spirit duty until Dec 31st next, when they will be superseded by the new tax on motor vehicles recommended by the Committee set up by the Ministry of Transport, whose report was recently laid before Parliament Motor cars will in future pay a tax of £1 per horse power unit The abatement of duty granted in the case of motor cars used by medical practitioners and veterinary surgeons will cease

HOUSE OF COMMONS

WEDNESDAY APRIL 14TH

Disease as a Ground for Divorce

Mr RENDALL moved "That in the opinion of this House it is desirable that legislative effect should be given without delay to the recommendations contained in the Majority Report of the Royal Commission on Divorce "

Lieutenant Colonel RAW, in seconding the motion, said he was not in favour of weakening the marriage tie in any way in normal conditions He would limit his remarks to three recommendations of the Royal Commission Majority Report —namely, those in reference to incurable insanity, habitual drunkenness, and the position of the person who was the wife or husband of one serving a commuted death sentence He proposed to consider them more from the medical aspect than any other In the United Kingdom we had unfortunately 140,000 persons who were certified as insane under the Lunacy Acts, and of that number 50,000 were suffering from what was called dementia, or degeneration of the brain itself, which disease was incurable He urged that dementia ought to be a ground for divorce Between 30 000 and 40 000 of these people were married, and in a very large number of instances the husband or wife might not know each other, in fact, a great many of them did not realise that they were married at all Out of a large experience amongst the insane he might tell the House that he had never known any case of recovery from dementia which had lasted for five years, that was the period suggested in the Majority Report as the time of detention under the Lunacy Acts after which a person who was suffering from this form of insanity should be examined at the request of wife or husband by a body of medical experts, who would then satisfy themselves as to whether the disease was curable If they were satisfied that it was incurable that might be a ground for divorce These cases were particularly hard amongst the poor He would not suggest that any other form of physical or mental disease should be a ground for divorce except the particular one he had mentioned, because as that was an incurable form there could not be any relief The sufferer might live for 40 or 50 years before death came Another form of mental disease which was most distressing was epilepsy, and certainly he hoped that the day would come when marriage would be prohibited to those suffering from it, and from other forms of mental disease, if only on the ground of the value to the State of healthy people whereas, as they knew heredity played a very important part in the production of all mental disease Habitual drunkenness destroyed the very basis of married life It was proposed that after a separation order had been granted, and had been in force for three years if the drunkenness continued, and there was no evidence of any improvement the husband or wife might petition for divorce It was said on very high authority, by those who had great experience in cases of the kind, that from 90 to 95 per cent of habitual drunkards died drunkards It had been shown by long experience that if habitual drunkenness continued for three or four or five years without any evidence of improvement there was practically no possibility or hope of any cure In his opinion these two conditions, which were unfortunately so prevalent, incurable insanity and habitual drunkenness for three years, were certain grounds for petition for divorce As regarded the commuted death sentence, he had seen cases of that sort, and he thought there was nothing more distressing than, say, that an innocent woman had to remain the wife of a convict for 20 or 25 years without any means of improvement

Mr R McNEILL moved the following amendment "That in the opinion of this House, while it is desirable to place the sexes on a footing of equality in regard to divorce, any change in the law which would impair the permanence of the marriage contract would be harmful to the best interests of the community " After criticising strongly the attitude of the Lord Chancellor and those who supported the Majority Report, Mr McNeill referred to the question of venereal disease as a ground for divorce under the head of cruelty He admitted that it was a very serious thing, but it was quite unnecessary to put it in as one of the grounds of cruelty, because under an agreed Bill it was already being laid down and accepted that venereal disease contracted before marriage would be a ground for nullity whereas if it was contracted after marriage it might be accepted as conclusive evidence of adultery upon which a decree might be granted Unless it was on account of the moral taint which attached to that particular disease he could not understand why it should be singled out As far as cruelty was concerned he did not know that there were not other communicable diseases that were as bad certainly as far as danger to life and to the children was concerned Speaking entirely as a layman he imagined that medical men would say that tuberculosis was a disease which might just as well be a ground for divorce as one of these more disgusting diseases Again, why was divorce to be granted because one of the parties was habitually intoxicated, whereas no relief whatever was given for the still greater vice of morphomania?

Mr EVELYN CECIL seconded the amendment

On a division the amendment was carried by 134 votes to 91

Civil Veterinary Service in India

Sir RICHARD COOPER asked the Secretary for India if he had received representations of the position of the civil veterinary service of India owing to the inadequate salaries of its officers and the impossibility of retaining men of ability, if he would say what increase in pay had been generally made in this service since 1914, and if he could announce the intentions of the Government of India on this matter —Mr MONTAGU replied Proposals for improving the pay and prospects of the Indian Veterinary Service have recently been received from the Government of India, and these are now being examined An announcement will be made as early as possible

Indian Medical Degrees

Mr WATERSON asked the Under Secretary of State for the Colonies if he was aware that persons holding Indian university medical and law degrees, such as L M and S and B A B L, who were eligible to practise medicine and law respectively in India, were not allowed to so practise in British East Africa, and, if so, would he state why in British East Africa, where the protectorate was first established with the object of safeguarding the interests of His Majesty's Indian subjects in that country, where Indian law was to day administered and where Indians preponderated both in point of numbers and in vested interests the said Indian university medical and law degrees were not recognised —Lieutenant Colonel AMERY replied, I explained to the honourable Member in my answer to his question on March 24th that Indian medical degrees or diplomas are recognised in the East Africa Protectorate provided that they entitle the holder to registration in the United Kingdom Advocates who have been admitted and are entitled to practise before one of the High Courts in British India are entitled to practise in the East African courts The general question of Indians in East Africa is under consideration between the Secretary of State and the Governor of the Protectorate

Municipal Hospital at Bradford

Mr LEONARD LYLE asked the Minister of Health whether he had given his consent to the establishment of a municipal hospital at Bradford, if so, for what special reason and on what conditions, whether this consent would be extended to other local authorities putting forward similar proposals, whether this step agreed with his policy as enunciated on Feb 26th, 1919 in the House and elsewhere at other times, whether he was now in a position to make a statement on the policy of his department in respect to voluntary hospitals, and whether, before sanctioning further hospitals supported out of public funds he would consider the position of voluntary hospitals, which had for years done invaluable public work, which were now hard pressed for funds to continue their efforts and which were bound to be most prejudicially affected by competition on the part of organisations which would never experience financial stress in respect either of upkeep, maintenance, or administration —Dr ADDISON replied I have sanctioned a scheme supported by all parties on the Bradford Council for the establishment of a municipal hospital which appeared to me to be the only practicable method of providing the institutional accommodation necessary to meet the needs of the city I see nothing in this decision inconsistent with the statement to which the honourable Member refers. As regards the last part of the question, I fully appreciate the value of the work done by the voluntary hospitals, and I am aware of the difficulties under which they are now labouring; but I am not yet in a position to make any definite statement.

Mr. Lyle: Does this mean that every other borough and town will be able to set up hospitals if they apply in the same way?—Dr. Addison: Pending further legislation, which we are now preparing, I have to consider cases on their merits as they arise. I decided as I did because it was the only way of meeting the necessities of the case.

Deaths from Anæsthetics.

Mr. Gilbert asked the Minister of Health whether, in view of the number of inquests held in London on persons who had died from anæsthetics, he could ask the Medical Research Committee to undertake a full inquiry into the whole question of anæsthetics and their administration with a view of saving life in the future; and whether, if this could not be done, he would have the recommendations of the Home Office Departmental Committee of 1910 on the same subject put into practice.—Dr. Addison replied: In reply to the first part of the question, having regard to the scientific investigations which have been made in comparatively recent years, I am not at present convinced that there is need for a further investigation of the character that appears to be suggested, but I will give the matter my careful consideration. I have nothing to add to what I have already said in reply to previous questions on the matter dealt with in the second part of the question.

The National Physique.

Mr. Clough asked the Minister of Health whether his department had now considered the disclosures affecting the health of the people in the report upon the physical examination of men of military age by National Service medical boards; and whether he was bringing to the notice of the local authorities more especially mentioned the desirability of taking such reform as was possible in the improvement of conditions of housing and industry.—Dr. Addison replied: The report to which the honourable Member refers is only part of a mass of evidence indicative of the need for the reorganisation and extension of public health services, and for better housing, but it is impossible within the limits of a reply to a Parliamentary question to set out all the steps to this end which have been taken or are in contemplation.

THURSDAY, APRIL 15TH.

Cost of Lunatic Patients.

Mr. Charles Edwards asked the Minister of Health whether he was aware of the continued increase in the cost of lunatic patients chargeable to boards of guardians maintained at lunatic asylums and that the 4s. per head now paid was totally inadequate; and whether he would introduce legislation to amend the Local Government Act, 1888, so as provide for boards of guardians receiving a much higher sum than the above.—Dr. Addison replied: I can only repeat that in view of the contemplated legislation for the reform of the Poor-law this point could not advisedly be dealt with at the present time.

Gratuity for Temporary Army Nurses in India.

Brigadier-General Croft asked the Secretary for India whether he would explain why nurses temporarily attached to the Indian Army nursing service, who had done such good work on active service both in hospital ships between Mesopotamia and German East Africa and Bombay and had served in Mesopotamia, had been refused a gratuity by the Pay Department in India, whilst members of the Indian Army nursing service had received such gratuity, in spite of the fact that the temporary nurses did their full share of work, and had to put up with many discomforts in the discharge of their duties.—Mr. Montagu replied: The Government of India were authorised on March 11th to issue the gratuity to the temporary nurses, and payment will be made as soon as possible.

Unqualified Opticians.

Mr. Sitch asked the Lord President of the Council if it was his intention to appoint a committee to inquire into the supply of spectacles and eyesight glasses generally by vendors not qualified by examination, on the same lines as those of the recent inquiry into unqualified dental practitioners.—Dr. Addison (Minister of Health) replied: The conditions prevailing which rendered necessary the recent inquiry referred to have no parallel in the circumstances connected with the production of optical appliances.

MONDAY, APRIL 19TH.

Pensions Medical Assessors.

Major Molson asked the Pensions Minister whether, as the medical men employed as assessors on sessional rates were continuously employed for the same hours as the medical commissioners, he could see his way to pay them as equitably and allow them leave with pay and sick leave with pay.—Major Tryon (Parliamentary Secretary to the Ministry of Pensions) replied: It is not considered that medical assessors employed at sessional rates are inequitably paid. Their conditions of service are different from those of whole-time medical commissioners or deputy commissioners. The question of leave with pay cannot arise in the case of men who are engaged on a sessional and not a salaried basis.

Ear Discharge as Pension Disability.

Mr. Harry Hope asked the Pension Minister whether a man suffering from discharge from the ears, contracted while serving in the army, was considered as having a disability; and whether he was aware that an ear specialist serving on the Pensions Board, Adelphi Hotel, Glasgow, had passed a man nil-disability though suffering as described.—Major Tryon replied: I am unable to reply to this question without further information. A man suffering from a disability attributable to or aggravated by his military service is eligible for an award of pension or gratuity according to the extent of his disablement. If the honourable Member will furnish me with particulars of the individual case which he has in mind I will have inquiries made and inform him of the result.

Pensions of Naval and Military Medical Men.

Mr. Robert Young asked the Pensions Minister if he would state the number of regular naval and military medical men employed by the Ministry who were in receipt of pensions; and how many of these received pensions of over £500 a year.—Major Tryon replied: There are 12 regular naval or military medical men employed on a salaried basis in the Ministry in various parts of the country who are in receipt of pension in respect of their naval or military service. Inquiry is being made as to the amount of pension in each case, and the honourable Member will be informed of the result.

TUESDAY, APRIL 20TH.

Influenza and Double Pneumonia at Sea.

Lieutenant-Colonel Arthur Murray asked the Secretary for War and Air if he would state the reason why Second-Corporal James Munro Selbie, No. W.R. 288,177, R.O.D., Royal Engineers, who, after disembarkation from H.M.S. *Czaritza*, died at Devonport on Feb. 8th from influenza and double pneumonia, and whose temperature on the arrival of the *Czaritza* was 103·4°, was not taken off the ship at Gibraltar and sent to hospital for treatment; and whether, in view of his gradually rising temperature, his chances of recovery would have been greater had he been so disembarked.—Mr. Churchill replied: I have no specific information as to the reason why Second-Corporal Selbie was not disembarked at Gibraltar. From the reports received, however, it appears that until after leaving Gibraltar the case was one of uncomplicated influenza, and as such would not ordinarily be taken off a ship en route, since adequate provision for treatment exists on board. I am advised that there is no reason to suppose that the complications which unfortunately led to this soldier's death would not have supervened at or about the same period, even though he had been disembarked at Gibraltar.

Leg Amputations and Mechanical Limbs.

Mr. Alfred Davies asked the Pensions Minister whether he could state the number of pensioners in the north-western region who had sustained leg amputations, and the number of arm amputations; how many had been supplied with mechanical limbs; the cost to maintain them in repair prior to the supply of the second mechanical limbs; and whether he could state how many cases had been supplied with a second mechanical limb.—Major Tryon replied: The number of pensioners in the north-western region with leg and arm amputations respectively are 3550 and 1500. All of these pensioners have been fitted with artificial limbs. In addition, there are about 140 serving soldiers who are not yet ready to be fitted. The cost of maintaining the limbs in repair both prior to the supply of the second artificial limb and after is borne by the Ministry of Pensions. The issue of second limbs has been proceeding steadily since last October, but I am unable to state how many of the pensioners now supplied with them reside in the north-western area.

Service Teachers and Death Gratuity.

Mr. Stanton asked the President of the Board of Education if he was aware that ex-Service teachers who were no longer A 1 medical category through wounds or other disablement contracted on military service did not become entitled to the death gratuity under the terms of the Education Act, 1918; was he aware that in order to ascertain their present medical state these disabled ex-Service teachers were compelled to undergo a medical examination at their own expense, and should the result be that they were below B 1 their next-of-kin would receive no gratuity; and whether, seeing that the medical state of these men was A 1 on entering His Majesty's forces, and that a teacher who stayed at home because of unfitness could claim the benefit for his next-of-kin, he would take steps to rectify this state of affairs.—Mr. FISHER replied: It is not the case that ex-Service men whose category was below B 1 are regarded as ineligible for a death gratuity. The total number of ex-Service teachers held to be ineligible for death gratuities is only 35.

Medical Men and Motor-car Duty.

The House went into Committee of Ways and Means on the Budget resolutions.

Sir J. BUTCHER raised the question of the abolition of the abatement of duty granted in the case of motor cars used by medical practitioners and veterinary surgeons He asked the Chancellor of the Exchequer to reconsider this matter, which would be a great hardship to these gentlemen, who have to travel about the country largely in pursuit of their profession.

Mr. CHAMBERLAIN said he would convey what the honourable Member had said to the Minister of Transport, who *was dealing* with this aspect of the Budget. The honourable Member might also consult with his right honourable friend on the matter.

Medical News.

Royal College of Physicians of Edinburgh, Royal College of Surgeons of Edinburgh, and Royal Faculty of Physicians and Surgeons of Glasgow.—The following candidates have passed the Triple Qualification Examinations:—

Third Examination

Ian Bruce Cummings, William Dunsmore Oswald, James Brown Hendry, William Taylor Davie, Robert Emmet O Keeffe, Herbert John Appleyard, Peter James Boyd Dyce, Raymond Levey, Marjory Jane Ann Ogilvie, William Muirhead Reid, Adrian Vintcent Bergh, Alan Wilson Hart, William Bethune Stott, William Alexander Blyth Clark, Leonard Edward Murray, and John Joseph Laurence McDonald

Pathology—James Readdie, Jemima Marianna McKechnie Calder, James Maxton McInnes, James McNie Campbell, and Joseph Alfred Henry Sykes

Materia Medica.—Edward James Allan, Alexander Wilson Buchan, and William Gray

Final Examination

Albert Christian Lornie, Harry Barlow, Robert Charles Dow, William Grant, Robert Smith, George Shuttleworth Barnett, Owen Fitzpatrick, George Murray Shaw Lindsay, Harry Cohen, Francis Paul McNulty Clarke, George Malayramon Kerry, Anand Shridhar Paranjpe, Elly Isserow, and John Francis Edward Burns.

Medicine—Douglas Chiene Scotland, Thomas Poole, John Stevenson, Thomas Arnoldus du Toit, and James Stewart Durward

Surgery—James MacGlachan, James Stewart Durward, and John Haldane Bain.

Midwifery—Walter Sydney Patrick, Douglas Chiene Scotland, Arthur Cuthbertson, Thomas Poole, William Wolfe Glucksman, Harry Wishart Whytock, James MacGlachan, Walter Granville Carew, and Ardishir Jahangerge Vakil

Medical Jurisprudence—John Gerald Collee, Reginald Edward Hopton, John Nagard, Alexandra Mary Limont, Ronald Gillan Clouston, Pauline Figdor, Gracie Olwen Davies Evans, and Andrew Wood Smith

Royal College of Surgeons in Ireland.—Professor Grafton Elliot Smith has been elected to the Mary Louisa Prentice Montgomery Lectureship in Ophthalmology. The subject of his first lecture, which will take place in October, 1920, will be "The Influence of Stereoscopic Vision on the Evolution of Man."

The Tuberculosis Society of Great Britain and Ireland.—A general meeting of this society will be held at the rooms of the Medical Society, 11, Chandos street, Cavendish-square, London, W., on Monday, April 26th, at 8 P.M. Dr. Clive Riviere will read a paper on Some Points in the Early Diagnosis of Pulmonary Tuberculosis, to be followed by discussion. Members willing to assist in the arrangements for the congress at Leeds on May 13th and 14th, 1920, are asked to communicate with the hon. secretary.

Royal Army Medical Corps Fund (Regular Army) and Royal Army Medical Corps Officers' Benevolent Society (Regular Army).—The annual general meeting of the Royal Army Medical Corps Fund will be held in the library of the Royal Army Medical Corps College, Grosvenor-road, S W., at 2 30 P.M., on Monday, June 14th. The Director-General will preside It is hoped that all subscribers who can spare the time will be present, and will freely express their views on any point connected with the Fund. The annual general meeting of the Royal Army Medical Corps Benevolent Society will take place immediately afterwards. Any officers desiring information regarding these Funds are requested to communicate beforehand with Lieutenant-Colonel E. M. Wilson, the secretary, at 76, Claverton-street, S W. 1, so that there may be no delay in dealing with any questions asked.

Royal Army Medical Corps Central Mess Fund.—The annual general meeting of subscribers to the Royal Army Medical Corps Central Mess Fund will be held in the Library of the Royal Army Medical Corps College on *Monday, June 14th, following immediately that of the* Royal Army Medical Corps Officers' Benevolent Society. Officers desiring information about this fund are asked to communicate beforehand with Captain J. T. Clapham, the honorary secretary, at 3, Homefield-road, Wimbledon, S W., so that there may be no delay in dealing with any questions which may be asked. Notice of any definite proposal which it may be desired to bring forward should be sent to the honorary secretary in order that it may appear on the agenda paper.

Auxiliary Royal Army Medical Corps Funds, 11, Chandos street, Cavendish-square, W. 1, honorary secretary, Colonel W. Hale White, R.A M C. (T.)—The annual general meeting of members of the above Funds will be held on Friday, April 30th, at 4 P M, at 11, Chandos-street, Cavendish square The annual reports will be presented and the officers for the ensuing year elected.

Mr. Frederic Hoffmann, chairman of the Hoff-*mann-La Roche Chemical Works, Ltd, died at Basle,* on April 18th, after a long illness

The Council of British Ophthalmologists.—A general meeting, which all British ophthalmic surgeons are invited to attend, will be held at the house of the Royal Society of Medicine at 1, Wimpole street, on Friday, April 30th, at 4 P.M The business will be to receive the report of the Council on the work done during the last two years, and to consider the following amendments to Rule 3 of the Council. In Clause *a* (permanent members) to add "and the Master of the Oxford Ophthalmological Congress." In Clause *b* (elected members) to substitute "ten members elected annually" where it now reads "nine," and "two by the Council of the Oxford Ophthalmological Congress," instead of "one" as at present.

Ophthalmological Society of the United Kingdom.—*The annual congress will be held at the House of the Royal Society of* Medicine from Thursday to Saturday, April 29th to May 1st. On Thursday, at 10 A M. to 12 30 P M., the presidential address will be given by Mr. J. B. Story, and papers will then be read as follow:—Mr. C. H. Usher: Enlarged Corneæ in Goldfish Mr. E. Treacher Collins: Megalo cornea and Micro cornea. Mr. John Rowan: Are not some Cases of Glaucoma Better Treated without Operation, and, if so, what are the Indications? Mr. A. Zorab: Later Notes on Aqueoplasty. Mr. T. Harrison Butler. Notes on Infection after Operations for Cataract. Mr. G. H. Pooley: Abnormalities of the Lacrymal Apparatus and their Treatment. Mr. G. Harvey Goldsmith: A case of Double Traumatic Dislocation of the Lens Mr. G. F. Alexander: (1) A Position of the Head Favourable to the Operation for Cataract; (2) an Operation for Advancement in Strabismus. In the afternoon a clinical meeting will be held at 2 45 P.M., at the Royal London Ophthalmic Hospital, City-road, when there will be an exhibit of books, drawings, and museum specimens belonging to the hospital, and cases will be shown by Mr. A. Lawson, Mr. A. Zorab, Mr. F. Juler, and others Mr. B T. Lang will show a new perimeter. At 4 P.M. Mr. Percy Flemming will give a demonstration on the Neighbourhood of Moorfields in Former Days. *After tea the discussion of cases will be resumed at* 5 P.M, and at 7.30 P.M. members will dine together at Oddenino's Imperia Restaurant, 60, Regent street (12*s.* 6*d* per head)

On Friday, at 10 A.M., a discussion on Diabetes in Relation to Diseases of the Eye will be opened by Sir Archibald Garrod and Mr. R. Foster Moore, and the following will speak Dr. O. Leyton, Mr. G. Mackay, Dr. Poynton, Mr. P. H. Adams, Dr. P. J Cammidge, Mr. Gray Clegg, Dr. A. Renshaw, Dr. C. O Hawthorne, Lieutenant Colonel F. P. Maynard, Mr. R. R. James, and others. The business meeting will be held at 5 30 P.M. In the evening, at 8 P.M., papers will be read as follow: Mr. H M. Traquair: Anatomically Separate Anterior Commissure at the Chiasma in a Case of Pituitary Tumour with Acromegaly. Dr. G. Holmes: Tumours Involving the Optic Nerves and Chiasma. Mr. M. L Hine: Primary Epithelioma of the Ciliary Body. Mr. E. Clarke. A Further Note on the Accommodation of the Eye. Mr. H. Neame: Cysts of the Retina Mr. W. Wallace: A Glyptic Method for Representing Certain Conditions *of the Fundus in Disease. Mr. A. W. Stirling:* A case of Melanoma of the Iris.

On Saturday a visit will be paid at 10 A M to St. Margaret's Hospital, Leighton road, Kentish Town, the special hospital of the Metropolitan Asylums Board for cases of ophthalmia neonatorum, where a discussion on the Prevention and Treatment of Ophthalmia Neonatorum will be opened by Dr. G. Fitzgibbon, Master of the Rotunda Hospital, and Mr. M. S. Mayou, and the following will speak: Mrs. Scharlieb, Dr. Macrory, Mr. S. Stephenson, Mr. M. Ramsay, Mr. J. Wharton, Mr. A. L Whitehead, Mr. T. Stevenson, and Mr. C. Killick.

General Nursing Council.—The following have been appointed to form the first General Nursing Council in England and Wales under the Nurses Registration Act of 1919. Mr. Priestley will act as chairman of the Council.

Appointed by the Privy Council.—Lady Hobhouse, Mr. J. C. Priestley, K.C.

Appointed by the Board of Education.—Hon. Mrs. Eustace Hills, Miss Batty Tuke, Bedford College.

Appointed by the Minister of Health.—Rev. G. B. Cronshaw (Radcliffe Infirmary, Oxford), Dr. E. W. Goodall, Dr. A. Bostock Hill, Dr. Bedford Pierce, Sir T. Jenner Verrall.

Nurses appointed by the Minister of Health.—Miss A. Cattell (private practice), Mr. T. Christian (Nurse, Banstead Lunatic Asylum), Miss A. Coulton (Matron, Shadwell Children's Hospital), Miss R. Cox-Davies, R.R.C. (Matron, Royal Free Hospital), Miss A. Dowbiggin, C.B.E., R.R.C. (Matron, Edmonton Poor-law Infirmary), Mrs. E. G. B. Fenwick (formerly Matron, St. Bartholomew's Hospital), Miss A. Lloyd-Still, C.B.E., R.R.C. (Matron, St. Thomas's Hospital), Miss M. MacCullum (Professional Union of Trained Nurses), Miss I. Macdonald (Royal British Nursing Association), Miss A. M. Peterkin (General Superintendent, Queen Victoria Jubilee Nurses), Miss E. Smith (Welsh Superintendent, Queen Victoria's Jubilee Institute for Nurses), Miss M. E. Sparshott, C.B.E., R.R.C. (Matron, Royal Infirmary, Manchester), Miss E. C. Swiss (Health Visitor for Willesden), Miss S. E. Villiers (Matron, Stockwell Fever Hospital), Miss C. Worsley (Matron, Liverpool Children's Hospital), Miss C. S. Yapp (Matron, Ashton-under-Lyne Poor-law Infirmary).

Increased Capitation Fees for Postal Medical Officers.—In response to representations from the Association of British Postal Medical Officers the capitation fee payable to postal medical officers has been raised from 8*s.* 6*d.* (inclusive of medicine and attendance) to 13*s.* from Jan. 1st last. The rate of remuneration for attendance in itinerant and emergency cases is to continue for the present at the recently revised rate of a half-yearly maximum of 10*s.* 6*d.*

A Conference on Dental Hygiene.—The Food Education Society will hold a conference on the Prevention of Diseases of the Teeth at the Albert Hall, Manchester, from May 13th to 15th. On the opening morning Dr. Harry Campbell will speak on the Extent and Consequences of Dental Disease, Dr. J. Sim Wallace on the Cause and Prevention of Dental Caries, and Dr. James Wheatley on Sweets and Dental Caries. In the afternoon the Effect of Certain Dietetic Factors on the Development of Teeth and Jaws will be discussed by Mrs. Edward Mellanby, and Dietetic Errors and other Causes of Irregularities of the Teeth by Dr. J. H. Badcock. In the evening Dr. Harold Waller will speak on Dental Disease among Nursing and Expectant Mothers. On May 14th in the morning Mr. F. M. Holborn, L.D.S., will open a discussion on Pyorrhœa, and in the afternoon Mr. W. H. Jones, L.D.S., will speak on the Importance of Dental Attention during First Dentition, and Dr. A. T. Pitts on the Temporary Dentition in Health and Disease. On May 15th a paper on Some Thoughts on the Problems of Prevention will be read by Mr. C. Doswell Wallis, L.D.S., and the meeting will conclude with some remarks on Aids to Fitness by Mr. C. E. Hecht, hon. secretary, Food Education Society, 265, Strand, London, W.C.2, to whom applications for membership (5*s.*) should be sent.

Death of Mr. E. A. Maling, M.R.C.S.—On April 12th, at the age of 81, after a busy, happy, and successful life, Edwin Allan Maling passed peacefully away at his residence at Darlington. He was descended from a well-known Sunderland family, his father being Mr. E. Haygarth Maling, the founder of the Durham County and Sunderland Eye Infirmary, and a former surgeon of the Royal Infirmary. Mr. Maling was educated in the Grange School, Sunderland, and King's College Hospital, London, and held the post of house surgeon of the Royal Infirmary, Sunderland, for five years from 1860. In those days infectious diseases were received in the general wards, and for some months he attended, practically single handed, many cases of small-pox and typhus fever during a severe epidemic in the town. On leaving the infirmary Mr. Maling joined as partner for ten years Mr. G. Welford, the first surgeon in the North of England to perform a successful ovariotomy. Later, he was appointed an assistant surgeon, and then full surgeon, and since his resignation from the active staff in 1892 had been honorary consulting surgeon to the Royal Infirmary. From 1894 to 1903 he was in partnership with Mr. W. Robinson, the present senior surgeon to the Royal Infirmary. For 40 years Mr. Maling was one of the best-known medical men of the town and district, his courteous manners and genial disposition, his cheery voice, even temper, and constant willingness to work made him one of the busiest practitioners of the North of England in his day; and although he retired from practice in December, 1903, and went to live in the country, hundreds of his old patients look upon his decease as the loss of a constant friend. Though reserved in speech, Mr. Maling was an excellent judge of character, and his great experience and sound judgment made him a rapid diagnostician. For 40 years Mr. Maling was a J.P. for the county of Durham, and for many years past he was chairman of the Sunderland County Bench. Mr. Maling married a daughter of the late Mr. James Hartley, sometime M.P. for the borough of Sunderland, who survives him. He leaves also three daughters and three sons, the youngest of whom, Mr. G. A. Maling, gained the V.C. early in the war whilst serving in the R.A.M.C.

The annual dinner of the West London Medico-Chirurgical Society will be held at the Wharncliffe Rooms, Hotel Great Central, on Thursday next, April 29th, at 7 P.M. Those intending to be present should communicate with Dr. J. F. Halls-Dally, 93, Harley-street, W. The triennial gold medals, in the gift of the society, will be presented during the evening.

A 23rd Divisional Medical Dinner will be held at Oddenino's, Regent-street, London, W., on June 5th, at 7.15 P.M. All ex-medical officers of the above division who wish to attend are requested to send their names (with remittance of 15*s.* for dinner, exclusive of wine) to Major W. J. Pearson, New University Club, St. James's-street, London, S.W. 1. Names should be submitted by May 20th.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Cmdr. O. Rees is placed on retired list with rank of Surgeon Captain.

Surg. Lieut.-Cmdr. L. Moss is allowed to withdraw from the Service with a gratuity.

Temp. Surg. Lieut. J. A. Watson is transferred to the permanent list.

ARMY MEDICAL SERVICE.

Col. W. E. Hardy is placed on half pay.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. and Bt. Col. C. B. Lawson retires on retired pay.

Lieut.-Col. J. P. Silver retires on retired pay on account of ill-health contracted on active service.

Lieut.-Col. H. A. Davidson relinquishes the acting rank of Colonel.

Lieut.-Col. C. J. O'Gorman relinquishes the temporary rank of Colonel.

Lieut.-Col. F. F. Carroll is restored to the establishment.

The undermentioned relinquish the acting rank of Lieutenant-Colonel: Major and Bt. Lieut.-Cols. W. F. Tyndale, B. A. Craig; Majors R. N. Hunt, H. W. Russell, C. J. Wyatt; Capt. and Bt. Majors R. E. Barnsley, P. S. Tomlinson.

Capt. and Bt. Major R. E. Barnsley to be acting Lieutenant-Colonel.

Capt. S. D. Robertson to be acting Major.

The undermentioned relinquish the acting rank of Major: Capts. C. Clarke, R. F. O'T. Dickinson, W. B. Rennie; Temp. Capts. P. K. McCowan, F. R. Brown, W. D. Cruickshank, C. H. B. Booth, S. Campbell.

Capt. R. H. Williams is placed temporarily on the half-pay list on account of ill-health contracted on active service.

Captains retiring receiving a gratuity: F. C. Davidson, R. B. Phillipps.

Officers relinquishing their commissions:—Temp. Lieut.-Col. A. G. P. Gipps (retains the rank of Lieutenant-Colonel). Temporary Majors retaining the rank of Major: E. B. C. White, T. W. Shaw, T. P. Devlin. Temp. Capts. H. Gardiner-Hill (on transfer to the R.A.F.) and (Brevet Major) A. E. Boycott (retains the Brevet rank of Major). Temporary Captains granted the rank of Major: T. M. Crawford, (acting Major) R. McRae, S. A. W. Munro, (acting Major) B. G. Brooke, W. V. Macaskie, J. Hewat. Captains retaining the rank of Captain: W. Tudhope, J. Keay. Temporary Captains retaining the rank of Captain: W. H. W. Mewhirter, M. Horan, F. B. Penfold, J. P. F. Waters, F. C. S. Bradbury, A. King, G. F. Hardy, J. G. Castellain, J. G. Ingouville, R. Lindsay, A. L. Robinson, F. Green, G. G. Old, A. Willatt, E. M. Balthaser, C. S. Wynne, J. Whiteside, A. H. H. Barclay, W. T. Munro, T. P. Hutchison, R. H. Rains, E. O. Gilkes, P. A. Dykes, E. D. Wellburn, E. Clarke, W. E. Stevenson, O. Carlyle, F. J. H. Begg, E. J. Blewitt, H. B. Waller, R. C. Macpherson, H. W. Bernard, E. S. B. Eames, T. W. Parry, S. Nockolds, M. A. Kirton, D. A. H. Moses, A. G. W. Thomson, H. G. E. Williams, P. J. O'Brien, A. J. Chillingworth, E. W. Blake, J. J. H. Ferguson, H. E. Gray, S. Wyborn, J. Menton, D. C. Norris, F. W. Rigby, R. B. Robson, D. M. Cox, G. H. F. Graves, D'A. I. Hamilton, R. T. St. J. Brooks, R. A. Wright, H. R. Souper, G. Bateman, W. N. Boog-Watson, J. G. Gemmell. Temp. Lieut. G. A. Fothergill (retains the rank of Lieutenant).

SPECIAL RESERVE OF OFFICERS.

Major M. R. Taylor relinquishes his commission on account of ill-health caused by wounds, and is granted the rank of Lieutenant-Colonel.

Capt. (acting Major) C. J. Rogerson to be acting Lieutenant-Colonel.

Captains relinquishing the acting rank of Major: H. D. Rollinson, A. F. L. Shields, M. Stewart, C. Armstrong.

TERRITORIAL FORCE.

3rd London General Hospital: Capt. S. H. Warren relinquishes his commission and retains the rank of Captain.

1st Western General Hospital: Capt. J. L. Roberts is restored to the establishment.

ROYAL AIR FORCE.

Medical Branch.—The undermentioned are transferred to the unemployed list: Capts. P. E. Williams, H. G. Anderson, L. W. Shelley, H. S. Baker, J. B. Barnett, D. C. Farquhason, A. Thompson, A. St. J. Hennessy, A. J. Davoren, G. McK. Thomas.

Dental Branch.—Capt. L. Wigoder is transferred to the unemployed list. Lieut. T. H. Jones relinquishes his commission and retains his rank.

INDIAN MEDICAL SERVICE.

Captains to be Majors: R. Knowles, W. E. Brierley, J. B. Lapsley, J. A. Shorten, R. B. S. Sewell, C. H. Fielding, W. L. Watson, J. W. Barnett, Madan Lal Puri, Satya Charan Pal, R. S. Townsend, R. B. Lloyd, A. C. Munro, A. G. Tresidder, G. G. Jolly, Sohrab Shapoorji Vazifdar, J. J. H. Nelson, E. S. Phipson, F. F. Smith, T. C. Boyd.

Captain to be temporary Major: R. E. Flowerdew.

Temporary Lieutenants to be temporary Captains: Justinian Anthony da Costa, Sundar Lal Bhandari, Armand Marcus Duarti, Aruldason Devasagayam, Aung Tun, Narendra Nath Ghosh, Priya Nath Lahiri, Satya Sakha Maitra, Sobha Ram Puri, Gopal Charan Sen, Bodh Raj Chaudhari, Yeshvant Prabhakar Gupte, Kannauthodath Padmanabha Menon, Shankar Ganesh Chavan, Joseph Costodio Sequeira, Gajanan Mukund Bhurke, Prabhaker Shanker Gupte, Nagendra Nath Saha (since deceased), Indra Bhusan Mazumdar, Bantwal Panduranga Baliga, Bhai Naranjan Singh Sethi, Ram Chandra Ganda, Gopal Chandra Ray, Dadabhoy Barjorji Doctor, Mohamed Ajmal Husain, Jiwanlal Kapoor, Yar Mohammad Siddique, Desraj Kehar, Coimbatore Venkataramanayar Krishnaswami, Dara Hormusji Bharucha, Dwarka Deish, Yeshwant Bhicajee Ranade, Har Bhagwan Vaid, Vittal Narain Benegal, Ramkrishna Venkata Rajam, Premankur De, Shiva Narain Govil, Bhagwan Das Myer, Harilal Prabhudas Dalal, Ambicaprasad Bajpayee, Krishnaji Nilkant Chhatre, Dayaram Harumal Mirchandani, Suresh Candra Banerjee.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY, April 29th.—Papers:—Prof. J. W. Gregory: The Irish Eskers.—Miss K. M. Curtis: The Life History and Cytology of *Synchytrium Endoboticum* (Schilb.) Perc., the Cause of Wart Disease in Potato (communicated by Prof. V. H. Blackman).—Mr. B. Sahni: On the Structure and Affinities of *Acmopyle Pancheri*, Pilger (communicated by Prof. A. C. Seward).

ROYAL SOCIETY OF MEDICINE 1, Wimpole-street, W.

MEETINGS OF SECTIONS.

Monday, April 26th.

ODONTOLOGY (Hon. Secretaries—G. Paton Pollitt, W. Kelsey Fry, J. Howard Mummery): at 8 P.M.

Papers:

Mr. Gerald B. Ash: A Factor in the Pathology of Pyorrhœa.

Mr. H. Stobie: *The Problem of Infection about the Apex of the Tooth.*

Tuesday, April 27th.

MEDICINE (Hon. Secretaries—W. Cecil Bosanquet, J. H. Thursfield): at 5.30 P.M.

Annual General Meeting—Election of Officers and Council for 1920-1921.

TUBERCULOSIS SOCIETY OF GREAT BRITAIN AND IRELAND, at the Rooms of the Medical Society, 11, Chandos-street, Cavendish-square, W.

MONDAY, *April 26th.—8 P.M., Paper*:—Dr. C. Riviere: Some Points in the Early Diagnosis of Pulmonary Tuberculosis, followed by a discussion.

CHILD STUDY SOCIETY, LONDON, at the Royal Sanitary Institute, 90, Buckingham Palace-road, S.W.

THURSDAY, April 29th.—6 P.M., Sir A. E. Shipley: Biting Insects and Children (illustrated by lantern slides).

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith, W.

MONDAY, April 26th.—2 P.M., Mr. B. Harman: Eye Department. 5 P.M., Dr. Morton: Carbon Dioxide Snow.

TUESDAY.—12 noon: Mr. T. Gray: Demonstration of Fractures, &c. 5 P.M., Mr. Banks Davis: *Clinical Lecture* (2).

WEDNESDAY.—2 P.M., Mr. D. Armour: *Demonstration of Surgical* Cases. 5 P.M., Mr. Addison: Ventral Hernia, Prevention and Treatment.

THURSDAY.—College closed. Annual Meeting, West London Hospital.

FRIDAY.—2.30 P.M., Dr. Pritchard: Demonstration of Medical Cases. 5 P.M., Dr. Burnford: Clinical Lecture with Cases.

SATURDAY.—10 A.M., Dr. A. Saunders: Medical Diseases of Children. 2 P.M., Dr. Owen: Medical Out-patients.

Daily:—10 A.M., Ward Visits. 2 P.M., *In-patient and Out-patient* Clinics and Operations.

K.—Dr. G. Keynes, Lond.; King's College Hospital Medical School.

L.—Mr. G. Lunan, Edinburgh; London (Royal Free Hospital) School of Medicine for Women, Asst. Sec. of.

M.—Ministry of Health, Lond.; *Dr. C. S. Myers, Lond.*; Ministry of Pensions, Lond.; Ministry of Agriculture and Fisheries, Lond.; Mr. G. Mayall, Belton; *Mr. A. McMillan, New Romney.* Dr. P. H. Manson-Bahr, Lond.; Miss H. Masters, Lond.

N.—National Safety Council, Chicago; Nurses' Co-operation, Lond.; Dr. H. B. Newham, Lond.; National Council of *Public Morals, Lond.*; National Association of Medical Herbalists of Great Britain.

O.—Miss K. O'Conor, Ware; Ophthalmological Society of the United Kingdom, Lond.; Dr. Orchard, Kingussie.

P.—Dr. A. G. Phear, Lond.; Capt. A. E. H. Pinch, Lond.; Dr. V. Pauchet, Paris; Mr. L. Paton, Lond.; Mr. J. H. Pringle, Glasgow; Dr. H. R. Phillips, Lond.; *Major W. J. Pearson, Lond.*

R.—Royal Society, Lond.; Royal Mail Steam Packet Co., Lond.; Mr. R. Robison, Lond.; Royal Faculty of Physicians and Surgeons, Glasgow; Royal Medical Benevolent Fund, Lond., Sec. of.; Royal Microscopical Society, Lond.; Royal Army Medical Corps Fund, Lond., Sec. of; Royal College of Physicians, Lond., Registrar of; Royal Infirmary, Manchester, Sec. of; Dr. W. Robinson, Sunderland; Dr. Rollier, Leysin; Royal Institution of Great Britain, Lond.; Royal Academy of Arts, Lond.; Royal College of Surgeons in Ireland, Dublin.

S.—Society for the Propagation of the Gospel in Foreign Parts, Lond.; Société des Sciences Médicales et Biologiques de Montpellier; Save the Children Fund, Lond.; Dr. E. Sayer, Lond.; Dr. H. Spencer, Lond.; Prof. W. Stirling, Manchester; Dr. G. F. Still, Lond.; Dr. A. H. Stephenson, Dickson, Tenn.; Sir Patrick Dun's Hospital, Dublin, Hon. Sec. of.

T.—Mr. H. M. Thornton, Lond.

U.—*University of Glasgow; University of Liverpool*, Appeal, Director of; United Services Medical Society, Lond., Sec. of.

V.—*Volta Review*, Washington, Associate Editor of.

W.—West London Post-Graduate College; *Miss Weir, Killybegs*; Dr. F. J. Waldo, Lond.; Dr. H. J. Walker, Brighton; Dr. R. T. Williamson, Manchester; Sir G. Sims Woodhead, Cambridge.

Appointments.

de Courcy, T. L., B.A., M.D. Dub., has been appointed Honorary Ophthalmic Surgeon to Royal Southern Hospital, Liverpool.

Puddicombe, T. P., M.B. Lond., D.P.H., Assistant County and School Medical Officer and Mental Expert under the Essex County Council.

Ryle, J. A., M.D. Lond., M.R.C.P. Lond., Assistant Physician to Guy's Hospital.

Saner, F. D., F.R.C.S., Surgeon to Out-patients, Great Northern Central Hospital.

Winton, W. B., M.D., B.C., M.R.C.P., Assistant Physician at the Hospital for Diseases of the Skin, Blackfriars.

Wyatt, R. B. H., M.R.C.S., L.R.C.P., Lecturer in Bacteriology in the University of Birmingham and Bacteriologist to the Queen's Hospital.

Certifying Surgeons under the Factory and Workshop Acts: Jones, E. P. (Roscommon); Moran, M., L.R.C.P. & S. Irel. (Tipperary); Murray, J., L.R.C.P. & S. Edin. (Consett); Quinn, R. A., M.B., Ch.B. St. And. (Caldbeck).

Vacancies.

For further information refer to the advertisement columns.

All Saints' Hospital (for Genito-Urinary Diseases), 49–57, Vauxhall Bridge-road, Victoria, S.W.—H.S. £100.

Ashton-under-Lyne District Infirmary.—Asst. H.S.. £200.

Barnsley, Beckett Hospital.—Jun. H.S. £200.

Bath, Royal Mineral Water Hospital.—Res, M.O. £250.

Battersea General Hospital, Battersea Park, S.W.—Res. M.O. £250.

Belfast, Municipal Sanatorium, Whiteabbey.—Res. Med. Supt. £650.

Birkenhead Borough Hospital.—Jun. H.S. £170.

Birmingham, Children's Hospital.—Res. M.O. and Res. Surg. O. £120.

Birmingham General Hospital.—Res. Surg. O. £180.

Birmingham, West Heath Sanatorium.—Med. Supt. £500.

Birmingham, Yardley-road Sanatorium and Anti-tuberculosis Centre.—Second and Third Asst. Res. M.O.'s. £450 and £400.

Bootle Borough.—M.O.H., &c. £800.

Bradford Children's Hospital.—H.S. £180.

Bradford Royal Infirmary.—Two H.S.'s £200.

Bridgend, Glamorgan County Asylum.—Jun. Asst. M.O. £350.

Brighton, Royal Sussex County Hospital.—H.P. £150.

Burton-on-Trent County Borough.—Asst. M.O. £500.

Buxton, Derbyshire, Devonshire Hospital.—H.P. £250.

Cairo, Egyptian Government, Ministry of Education.—Professor of Pathology. L.E. 1200–1400.

Camberwell Infirmary, Brunswick-square, Camberwell.—Locum Tenens Asst. M.O. £7 7s. weekly.

Cambridge, Addenbrooke's Hospital.—H.S. £130.

Cancer Hospital, Fulham-road, S.W.—Three Anæsthetists.

Canterbury, Kent and Canterbury Hospital.—Res. M.O.'s. £200.

Cardiff, King Edward VII. Hospital.—Female H.S. £200.

Croydon Union.—M.O. for South Croydon District. £200.

Derby, Derbyshire Hospital for Women, Bridge-street.—Hon. Asst. S.

Durham University.—Asst. in the Dept. of Bacteriology. £600.

Elizabeth Garrett Anderson Hospital, Euston-road, N.W.—Female Jun. Asst. P., Clin. Assts., Two H.S.'s, H.P., and Obstet. Asst. £50 each.

Evelina Hospital for Children, Southwark, S.E.—H.S. £160.

Evelina Hospital for Sick Children, Southwark Bridge-road, S.E.—Medical Radiographer. £120.

Exeter City.—Asst. Tuberc. O. and Asst. M.O.H. £500.

Fulham Infirmary, St. Dunstan's-road, Hammersmith, W.—Jun. Asst. M.O. £300.

Gloucestershire Royal Infirmary and Eye Institution.—H.P. £175.

Great Yarmouth County Borough.—Asst. M.O.H. £500.

Hereford County and City Mental Hospital.—Second Asst. M.O. £350.

Hospital for Sick Children, Great Ormond-street, London, W.C.—Surg. Registrar. £200.

Huddersfield Royal Infirmary.—Asst. H.S. £150.

Inverness District Asylum.—Jun. Asst. M.O. £250.

Ipswich.—Asst. County M.O.H. £500.

Ipswich, East Suffolk County Education Committee.—Dent. S. £450.

Isleworth Infirmary and Workhouse and Central Scattered Homes.—Two Asst. M.O.'s. £300.

Leeds City, Tuberculosis Sanatorium, Killingbeck.—Med. Supt. £500.

Leeds Public Dispensary.—Res. M.O. £200.

Leeds University.—Demonstrator in Exp. Phys. £250.

Lincoln, Lindsey County Council.—Female Asst. M.O. £550.

London Temperance Hospital, Hampstead-road, N.W.—Cas. O. £120.

Loughborough and District General Hospital and Dispensary.—Res. H.S. £200.

Macclesfield, Cheshire County Asylum, Parkside.—Asst. M.O. £350.

Macclesfield General Infirmary.—Res. H.S. £200.

Maidstone, Kent County Ophthalmic Hospital.—H.S. £250.

Manchester County Asylum, Prestwich.—Asst. M.O. £450.

Metropolitan Asylums Board, North-Eastern Fever Hospital, Tottenham, and Western Fever Hospital, Fulham.—Consulting Otologist. £250.

Middlesbrough, North Ormesby Hospital.—Asst. H.S. £175.

Middlesbrough, North Riding Infirmary.—H.S. £200.

Mount Vernon Hospital for Tuberculosis and Diseases of the Chest, Northwood, Middlesex.—Asst. Res. M.O. £200.

Newcastle-upon-Tyne, City Hospital for Infectious Diseases.—Res. Med. Asst. £350.

Newport, Mon., Royal Gwent Hospital.—Fourth Res. M.O. £180.

Norfolk County.—Tuberc. O. £600.

Northampton General Hospital.—H.S. £150.

North Riding of Yorkshire County Council, Education Committee.—Asst. Sch. M.O. £500.

Northumberland County.—Sch. Med. Insp. £500.

Norwich City.—Asst. M.O.H. and Res. M.O. at Isolation Hospital. £450.

Norwich, Norfolk and Norwich Hospital.—Cas. O. £200.

Nottingham Education Committee.—Sch. Dent. £500.

Nottingham, Notts County Council.—Female Asst. Child Welfare M.O. and Asst. Sch. M.O. £500.

Oldham Royal Infirmary.—Third H.S. £200.

Peterborough City and Borough.—M.O.H. £650.

Portsmouth Royal Hospital.—H.S. £150.

Preston Royal Infirmary.—Jun. H.S. £180.

Queen Charlotte's Lying-in Hospital, Marylebone-road, N.W.—Asst. Res. M.O. £60.

Queen Mary's Hospital for East End, Stratford, E.—H.P.

Rochester, Kent, St. Bartholomew's Hospital.—Jun. Res. M.O. £150.

Royal Free Hospital, Gray's Inn-road, W.C.—Sen. Res. M.O. £200.

St. John's Hospital for Diseases of the Skin, 49, Leicester-square, W.C.—Two Asst. P.'s.

St. Marylebone General Dispensary, 77, Welbeck-street, Cavendish-square, W.—Res. M.O. £200.

St. Mary's Hospital for Women and Children, Plaistow, London, E.—Res. M.O. £200.

Salford Education Committee.—Asst. Sch. M.O. £400 to £600.

Salford Royal Hospital.—H.S. £150.

Sheffield, East End Branch of the Children's Hospital.—H.S. £150.

Sheffield Royal Hospital.—Asst. Cas. O. £150.

Sheffield Royal Infirmary.—Two H.S's and one Ear, Nose, and Throat H.S. £150.

Shoreditch Hospital, 201, Hoxton-street, N.—Two Res. Asst. M.O.'s. £400 and £350 respectively.

Stamford, Rutland, and General Infirmary, Stamford.—H.S. £200.

Stoke-on-Trent, North Staffordshire Infirmary.—H.S. £200.

Sunderland Royal Infirmary—H.P. £200.

Swansea General and Eye Hospital.—Two H.S.'s. £200.

Torquay, Torbay Hospital.—H.S. £200.

Trowbridge, Wilts County Council.—Third Sch. Dent. £400.

University of London, King's College, Department of Physiology.—Demonstrator in Physiology. £300.

University of London, St. Mary's Hospital Medical School.—University Chair of Physiology. £900.

Wells Asylum, Somerset.—Sen. Asst. M.O., . £400.

West Bromwich and District Hospital.—Res. H.S. £200.

West Ham Union.—Two Specialist Consultants. £150.

Western Dispensary, Rochester-row, S.W.—Vacancy on Med. Staff.

Wimbledon, Borough of.—Asst. M.O.H. £500.

Wolverhampton and Staffordshire General Hospital.—Hon. P. Also Hon. M.O. for X Ray and Electro-Therapeutic Department. £100.

Woolwich Tuberculosis Dispensary, Maxey-road, Plumstead, S.E.—Asst. Tuberc. O. £500.

Worcester County Borough.—Asst. M.O.H. £500.

Worcester County and City Mental Hospital, Powick.—Jun. Asst. M.O. £300.

The Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Blarney, Kingston-on-Thames, Menai Bridge, and North Berwick.

Births, Marriages, and Deaths.

BIRTHS.

Benson.—On April 17th, at Fiddington House, Market Lavington, the wife of J. R. Benson, F.R.C.S., of a son.

Easton.—On April 7th, at a nursing home, the wife of Wilfred A. Easton, M.R.C.S., L.R.C.P., L.D.S., Wimbledon Park, of a son.

Farnfield.—On April 14th, at Ashburnham-road, Hastings, the wife of Dr. J. S. Farnfield, of a son.

Martin.—On April 7th, at Park-gardens, Glasgow, the wife of Captain W. Strelley Martin, M.C., R.A.M.C., of a daughter.

Pinnock.—On April 12th, the wife of Dudley Denham Pinnock, F.R.C.S., of a son.

Pridham.—On April 12th, at the Nursing Home of St. Andrew's Hospital, Dollis Hill, the wife of J. A. Pridham, M.C., L.R.C.P., M.R.C.S., of a daughter.

Vlasto.—On April 15th, at 29, Porchester-terrace, W. 2, Chrissy (née Croil), the wife of M. Vlasto, F.R.C.S., of a daughter.

Wilkinson.—On April 16th, the wife of Dr. Stephen Harold Wilkinson, of a daughter.

MARRIAGES.

Abraham—Francis.—On April 21st, at St. Martin-in-the-Fields, London, J. Johnston Abraham, M.D., F.R.C.S., C.B.E., D.S.O., to Lilian Angela Francis, F.R.M.S., eldest daughter of Dr. H. A. Francis.

Edwards—Hoskin.—On April 13th, at the Chapel Royal, Savoy, Arthur Tudor Edwards, M.C. Cantab., F.R.C.S., to Evelyn, only daughter of the late D. Theophilus Hoskin, J.P., and Mrs. Hoskin, of Cumberland-mansions, W., and Cornwall.

Garman—Locke Lancaster.—On April 15th, at St. John the Evangelist, Notting-hill, Dr. Edwin C. Garman, to Florence, widow of Robert Locke Lancaster, and daughter of the late Rev. Canon Gandell.

DEATHS.

Collis.—On April 14th, at Sandown, Isle of Wight, Dr. Robert William Collis, in his 65th year.

de Castro.—On April 14th, suddenly, at Drummond-road, Bournemouth, George de Castro, M.R.C.S., L.R.C.P.

Henderson.—On April 19th, at Littlecot, Harnham Hills, Salisbury, Thomas Bonhote Henderson, M.A., M.B., F.R.C.S.

Hunt.—On the 17th April, at Uplands, Tettenhall, Staffs (the residence of his brother-in-law), Joseph William Hunt, M.D., B.S. (Lond.), formerly of Woodchester, Upper Clapton, aged 68. No flowers.

Tyrrell.—On April 14th, at Alexandra-road, N.W., Walter Guy Beauchamp Tyrrell, M.R.C.S., L.R.C.P., D.P.H., of Hilmarton-road, N., in his 59th year.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

LAMBETH MEDICAL DEGREES

IN the Middle Ages degrees in divinity, law, and medicine were granted by the Popes of Rome independently of the universities, and prior to the Reformation the Archbishop of Canterbury exerted his right to confer academic degrees in this country by virtue of his position as *legatus natus* of the Holy Father After the break with papal authority, this privilege of the See of Canterbury was confirmed by statute in 1534 (25 Hen VIII c 21), which provided that the Archbishop of Canterbury shall have power to grant "all manner such licenses, dispensations compositions, faculties grants, receipts, delegacies, instruments, and all other writings for causes not being contrary or repugnant to the Holy Scriptures and laws of God, as heretofore hath been used and accustomed to be had and obtained by your Highness or any of your most noble progenitors, or any of your or their subjects at the See of Rome " Degrees are understood to be included in the term "faculties," and the episcopal privilege has, during the four centuries which have elapsed, never been abrogated The Index to the Statutes in Force still speaks of the "power of the Archbishop of Canterbury to grant Dispensations and Licenses "

But although always existing, the right has been exerted in very varying degrees at different times Cranmer is known to have commissioned the Bishop of Norwich to confer the degree of D D on a certain Eligius Ferrers Prior to the Restoration there is record of only seven bestowals, none of them being medical degrees In 1660 Archbishop Juxon conferred an M D and an M B degree, and between his death in 1663 and the year 1848 there were 451 Lambeth graduates, 31 of whom secured the right to place M D Cantuar after their names, and one—namely, Peter Dent, of Trinity College, Cambridge—became M B Cantuar in 1678

In 1858, when the right to practise medicine became strictly limited by statute, a section in the Medical Act provided for the registration of Lambeth medical degrees if granted prior to the passing of the Act The gentlemen eligible for such registration are contained in the following list of Lambeth doctors of medicine, which is complete from the beginning of last century up to the passing of the Medical Act —

Year of conferment	Name and other qualifications so far as known
1803	Robert Pope
1806	Thomas Day
1817	Whitlock Nicoll, M R C S, M D Aberd and Glasg
1818	John Day
1819	Carr Ellison Lucas
1822	William Oliver Locke
1824	James Rumsey
1825	Daniel Jarvis
1826	Edward Grimstone
1827	Sir Charles Mansfield Clarke, Bart, M R C S *F R C P Lond*
	William Chandler
1828	William Samways Oke L R C P M R C S, L S A
1836	Sir David Davies, K G H, L R C P
1840	Robert Hull, L R C P, M R C S
1841	Sir William Hyde Pearson
1849	Joseph Laurie, L R C S Edin
1850	William Bayes, M R C S, L R C P
	Edmund Charles Johnson, M R C S, F R C S
1851	Frederick Gilder Julius M R C S, L S A, F R C S
	John Green Bishop, M R C S
1854	George Canney, M R C S, L S A
1855	John Hodgson Ramsbotham, M R C S, L S A, M D Erlangen
	Ralph Barnes Grindod, L S A, M D Erlangen
1856	William Sharp, M R C S, L S A
	Edward Phillips, M R C S
1858	Edward Cronin, M D Dub
	Edmund Smith, M R C S, L S A.
	William Baker

Shortly after the passing of the Act three further degrees were conferred, viz —(1861) John Rayner, L S A, M R C S, M R C P Edin, and Edward-Westall, (1862) William Sherwin But the practice then ceased, and it is now nearly 60 years since an M D Cantuar has been granted, and, as far as we know, the death of the last holder was recorded in the columns of THE LANCET of April 18th, 1896 —

> SHARP —On April 10th at Llandudno, William Sharp, M.D Lambeth, F R S of Rugby, aged 91

With a few possible exceptions, it will be seen that in all, or nearly all, of these pontifical conferments the legal right to practise medicine was already there This was certainly so in the case of Sir Charles Mansfield Clarke, to whom Archbishop Manners Sutton granted an M D in the year 1827, and who had held the diploma of M R C S since 1802 On this occasion a letter signed "Peter Permissus," addressed to Sir Henry Halford, P R C P, appeared in THE LANCET (April 12th, 1828), in which the writer admits that no class of men understand better the value of learning than the clergy, and goes on —

> 'The whole of the existing bench of Bishops have been educated at Oxford or Cambridge, and they feel reluctant in ordaining such as present themselves from other universities The College of Physicians insist on a residence at certain universities and a previous diploma before they will proceed to the examination of a candidate Why then should the mitre, in defiance of these wholesome establishments interpose an unrepealed abuse, an obsolete remnant of monkish fraud and imposture, to sanction a probable depredation on the health of his Majesty s loyal subjects?

He further inquires concerning the ceremony "Did his Grace's chaplain plumb his depth in Latin? Did he sound him in Greek? or did he gauge his orthodoxy? What was the nature of the holy diploma obtained?" And although "Peter Permissus" seems to have been misinformed in regard to the previous medical training of this particular candidate, there may be a point in his blunt questions.

THE RHEUMATIC SCHOOL CHILD

IN the course of a lecture on Medical Inspection in Schools at the Day Training College of the L C C, Southampton row, London, W C, on April 14th, Dr F S Langmead pointed out that rheumatism is essentially a disease of children, the simulating symptoms at other ages being frequently due to different causes, such as arthritis and rheumatic gout Rheumatism and tuberculosis are both common diseases among school children, said the lecturer, both very liable to recur after apparent cure, and both leading to considerable crippling Among the causes of rheumatism he placed hereditary influence, damp houses, and low lying districts A chart of the distribution of the disease throughout London showed that the cases were most frequent in the neighbourhood of buried rivers, along the Thames, Wandle, and the tributaries, and along the sites of the Fleet and the East and West Bourne The proportion of girls to boys affected was about 2 to 1 The organism causing the disease gained entrance into the body of the susceptible individual chiefly through the tonsils in all probability, tonsillitis was often the precursor of acute rheumatism An investigation made by the lecturer on 2556 children of all ages had confirmed the observation that the tonsils were enlarged four times as frequently in rheumatic as in normal children Rheumatism not infrequently followed scarlet fever, which also produced sore-throat and tonsillitis Other possible modes of ingress for the infection were the throat, the nose, the naso pharynx, mouth, and perhaps also the bowel Rheumatic children formed a fairly definite type, being often bright and intelligent, though not up to standard in consequence of loss of time by illness They were excitable and nervous, worked in fits and starts, and showed want of application, as well as being fidgety and imaginative Imagination showed itself in disturbed dreams The manifestations of the disease were numerous, and included fever, swelling of joints, sweating, furred tongue, a curious sour smell, and painful and tender joints There might be pains in the limbs, as distinct from joints, in the muscles and in the bones The so called growing pains were rheumatic symptoms, showing that the foundation for future rheumatic trouble was being laid In addition there might be bleeding from the nose, pains in the pit of the stomach, increasing pallor, anæmia, chorea, and, most important of all, heart disease Statistics showed that among the physically defective in schools heart cases constituted about a third of the physically defective children and heart conditions were the chief cause of death The heart cases in our hospitals had their foundation in school life Precaution should be taken to prevent a fresh attack of rheumatism, but it was, of course, impossible to mend a damaged heart The children should be protected from cold and wet and receive medical treatment at the first manifestation of disease Chorea might occur without any other symptom of rheumatism, its differentiation from habit spasm or tick was important The symptoms of tuberculosis must be carefully distinguished from those of rheumatism, observations in this connexion should be especially directed to family history, want of gain in weight (not necessarily loss of weight), anæmia, poor appetite, tiredness, indigestion, and cough as symptomatic of tuberculosis At home restless sleep and a good deal of sweating might be noticed and should be inquired into An essential difference in the treatment of the two diseases was that while rheumatic children should be protected from the weather consumptive ones should be in the open air at all possible times

THE INVENTOR OF THE INCUBATOR.

THE death of Mr. Charles Edward Hearson on March 27th, in his seventy-fifth year, should not pass unnoticed by medical men. Mr. Hearson's name is indissolubly connected with the incubator for hatching eggs, for it was the simplicity and ingenuity of his heat regulator which brought the incubator into popular use; and when the science of bacteriology was in its infancy some 40 years ago he was asked by a leading bacteriologist to adapt his thermostat for the cultivation of micro-organisms. Since that day Hearson's incubators have been in use in every research laboratory throughout the world, while the first thermostat constructed by him still survives in working order in a London laboratory. Besides the biological incubator he designed a number of other appliances to meet the requirements of the bacteriologist. Early in the war the firm with which he was connected supplied at 12 hours' notice the apparatus required for the equipment of a special laboratory to cope with the outbreak of cerebro-spinal fever. Another popular and useful invention was the "thermostatic nurse," in extensive use for feeble and premature infants. Mr. Hearson was for eight years the representative of Camberwell on the Metropolitan Water Board, and during part of that time was chairman of the Works and Stores Committee. During his chairmanship he cut the first sod in the construction of the Island Barn reservoir and presided at the public opening of the Walton pumping-station. Little known to the public, his life greatly conduced to the advancement of medical science.

DUBLIN RADIUM INSTITUTE.

A BRIEF report by Dr. Walter C. Stevenson, of the Radium Institute of Dublin, has just been published as an appendix to the report of the Council of the Royal Dublin Society for the year ended Oct. 31st, 1919. The quantity of radium emanation issued during the year amounted to 3215·4 millicuries, and it appears that the work of the institute is carried out entirely by means of emanation tubes and applicators, no radium salt apparatus being employed. The report is in such general terms that no indications are given as to the line of treatment adopted, and the dosage and exposures employed in the various conditions—an omission which is disappointing. Much energy has been expended on the treatment of military orthopædic cases, the statement being made that radium therapy shortens the period of convalescence following gunshot wounds, and that it aids recovery by softening scar-tissue, improving the nutrition of the injured part, and exerting an analgesic effect on painful and tender scars. Two of the Government patients were treated for cancer, one suffering from advanced condition of carcinoma of the tongue. The treatment caused considerable local improvement, and enabled the patient to recover sufficiently to go home for a fortnight's leave, though he died three months later. The list of civil patients comprises 19 cases of malignant disease, most of them in so advanced a stage as to preclude any cure; the treatment was palliative, and the majority was lost sight of. One tongue case is recorded as having been seen four months after treatment, and looking almost well. The report also alludes to cases of cancer of the œsophagus and of Hodgkin's disease, in which definite, though apparently only temporary, improvement followed upon radium treatment. The report is worthy of perusal by all interested in radium therapy.

THE INCISION OF SMALL-POX PUSTULES.

Dr. C. G. S. Baronsfeather writes from Pakhoi, South China, under date Feb. 25th: We are having a serious outbreak of small-pox here just now, for, although the Chinese believe in vaccination, coolies, women, slave-girls—regarded by them as "trash"—are only vaccinated when convenient. As a result we see some serious cases, including confluent types.

One little girl in the isolation ward of the C.M.S. Hospital here seemed so miserable with a mass of pustules which were confluent in places that, remembering the misery caused in my own youngster by a single scabies pustule and the immediate relief when it was opened, I opened about 30-40 of the pustules on the face. Next day the child was remarkably better, her eyes were open, and she had ceased groaning. After waiting to assure myself that the improvement was lasting, I took a sharp-curved bistoury and opened some 30 more, in some cases the pus squirted out, and a mixture of olive and eucalyptus oils was then rubbed over the head and face. On the principle that pus under tension should always be released, and variola being a disease confined largely to the skin, death ensuing from toxic absorption, common sense suggests this method of treatment, although condemned in text-books as old-fashioned and useless. A dilute solution of iodine tincture was painted over the face in all cases during the opening days, but did not give appreciable relief.

PUBLIC HEALTH IN SOMALILAND.

No reliable information is available as to the Somali population in the Protectorate, but 300,000 is generally quoted as an approximate figure. A Census of the alien community (excluding Europeans) was taken in the three coast towns in 1911, the return then being as follows Indian, 741; Arabs, 1857; and mixed population, 798.

The general public health during 1918-19 was not as good as in previous years, the admissions to hospital showing a great increase. The influenza epidemic visited Somaliland early in November, 1918. The disease was first noticed at Berbera, whither it had doubtless come from Aden, where it had been present for some time. From Berbera it spread very rapidly throughout the Protectorate, and within a fortnight had reached all outlying stations. The epidemic had subsided by the end of December. The disease was often complicated by pneumonia, which accounted for most of the deaths recorded. It is estimated that at least 50 per cent. of the Somali population contracted the disease and that 5 per cent. died. There were no deaths among the Europeans in the Protectorate.

There was an appreciable decrease in the number of malarial cases recorded. There would appear to have been an increase of relapsing fever among the natives, and, as usual, nearly all the cases occurred at Hargeisa, where the *Ornithodorus moubata* tick is found. It is probable, however, that the apparent increase is due to the fact that greater attention is being paid to the disease and that the natives are beginning to realise the benefits of early treatment.

Excellent results have been obtained from intravenous injections of galyl or salvarsan. In many cases one injection effected a cure, although more chronic cases did not respond so readily. Hardly any cases occurred among the troops or police owing to the preventive measures taken.

An epidemic of small-pox was kept well in hand by preventive measures, but by March 31st, 1919, some 70 deaths had been recorded, mostly at Burao. A few cases of mumps were recorded during the year; a very similar disease is seen among camels in Somaliland and possibly elsewhere. The prevalent diseases are pulmonary tuberculosis, venereal diseases, chronic rheumatism, bronchitis, conjunctivitis, and ulcers. Scurvy occasionally occurs, but is very much on the decrease.

The total rainfall in Berbera in 1918 was 1·93 in.; in the interior it was considerably more than this, but up to the present it has not been practicable to keep records, except in Berbera. The highest shade temperature recorded was 114° F. in July, while the lowest was 59° in January. Away from the sea coast the climate is chiefly remarkable for its very dry character, and in the interior it is comparatively healthy throughout the year; but in the coast belt during the *Kharif* season—i.e., from June 1st to mid-September—the climatic conditions are exceedingly trying, particularly for Europeans, the effect on the nervous system being very marked. During this period terrific gales of hot sand-laden winds are prevalent and the heat is intense, the thermometer registering 105° to 115° in the shade, and seldom falling below 100° at night. During November, December, January, and February the climatic conditions at the coast greatly improve.

The general health of Europeans was not good during the year; the average number resident was only 36, and eight were invalided to England.

THE MEDICAL STUDENT'S GENEROSITY.

To the Editor of THE LANCET.

SIR,—The case of blood transfusion before operation, as cited by Dr. H. Williamson in his article in THE LANCET of April 17th, is certainly interesting and instructive, and he is to be congratulated on his successful treatment of the case. As blood transfusion is likely to become popular in the future and donors will be much in request, I beg to suggest that the students should not be permitted to be the donors for the following reasons: 1. A medical student's life, especially whilst attending hospital, is not one of the healthiest, and he requires all his reserve strength for his immediate work and for his future struggle in life. 2. It is the duty of the relations of the sick person and not the duty of the student to sacrifice themselves; the former can practically always be called upon if the emergency arises. 3. Venesection is not always such a safe and simple procedure as described in medical literature. I have seen several patients whose wounds have not healed by first intention, and whose convalescence has been tedious and prolonged. 4. It is very difficult for a student to refuse when requested to offer himself as a donor, as there is a chance of him being slighted by his seniors and scoffed at by his equals—a thing no man appreciates. 5. It is not fair to students' parents, who spend much money and care to keep their sons in good health for their future career.

I am, Sir, yours faithfully,

H. J. WALKER, F.R.C.S. Edin., M.R.C.S., L.R.C.P.

Brighton, April 18th, 1920.

ON Wednesday last Miss L. A. Francis, F.R.M.S., bacteriologist during the war to the Central London Ophthalmic Hospital, and eldest daughter of Dr. H. A. Francis, was married to Dr. J. J. Abraham, C.B.E., D.S.O., author of "The Surgeon's Log."

Dr. O. is thanked for his suggestion.

G. G. J.—The interesting table is receiving attention.

ROYAL A

THE LANCET, MAY 1, 1920.

Milroy Lectures
ON
THE HIGHER FUNGI IN RELATION TO HUMAN PATHOLOGY.

Delivered before the Royal College of Physicians of London

BY ALDO CASTELLANI, C.M.G., M.D.,
M.R.C.P. LOND.,
PHYSICIAN TO THE TROPICAL HOSPITAL (MINISTRY OF PENSIONS);
LECTURER AT THE LONDON SCHOOL OF TROPICAL MEDICINE.

LECTURE III.

Delivered on March 4th, 1920.

THE rôle played by fungi in skin diseases is of extreme importance; it suffices to bear in mind the various trichophytoses, the blastomycoses, the sporotrichoses, the mycetomas. It is interesting to note, however, that though, of course, during recent years the all-important rôle played by the higher fungi in dermatology has been amply recognised, not many decades ago most authorities denied them any importance, some considering such organisms to be merely saprophytes, and others going so far as to state that the so-called fungi found in the epidermis and the hairs did not exist, these structures merely representing a granular degeneration of the epidermial cells.

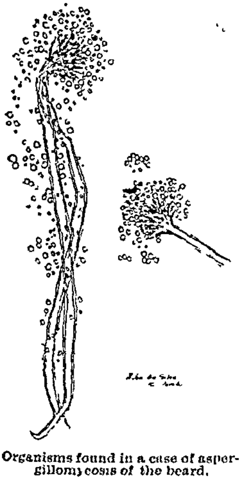
These affections may be separated to a certain extent into two groups: (1) The trichomycoses; (2) the dermatomycoses *sensu stricto*.

THE TRICHOMYCOSES.

Of this group I shall say a few words on (1) aspergillomycosis of the beard, and on (2) trichomycoses axillaris, flava, rubra, et nigra.

Aspergillomycosis of the Beard.

FIG. 1.



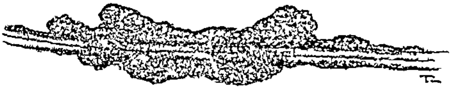
Organisms found in a case of aspergillomycosis of the beard.

Aspergillomycosis of the beard and moustache appears under the form of minute dark-greyish nodules, one or several on each individual hair. The first case I saw in Equatorial Africa in 1902 in an Indian merchant; later Chalmers and myself observed several such cases in Ceylon. The fungi found are generally of the aspergillar type (Fig. 1), but occasionally organisms of genus *Penicillium* may be seen. The simplest treatment consists, of course, in shaving, but if the patient does not wish to shave turpentine will be found useful..

Trichomycoses Axillaris, Flava, Nigra, et Rubra.

This condition has been known under the term lepothrix for many years, but until recently the various types were not differentiated and the ætiology was not completely cleared. In the large literature on the subject the affection is ascribed to the most diverse germs: Elsner describes a diplococcus, Payne, Patterson, and Pick various bacilli, among which is *B. prodigiosus*. The condition is characterised by the presence on the hairs of the axillary region (occasionally of the pubes also) of small nodular formations. These nodules may be, in my experience, yellow, or black, or red. I have therefore differentiated three varieties of the affection: Trichomycosis axillaris flava, Trichomycosis nigra (Figs. 2 and 3), Trichomycosis rubra.†

FIG. 2.



Trichomycosis axillaris flavis

FIG. 3.

Trichomycosis axillaris nigra

At times one axilla may show the variety nigra, and the other the variety rubra or flava; occasionally, the same axilla and even the same individual hair may present two varieties at the same time. In Ceylon and Southern India the three kinds—yellow, black, and red—are common; in North Africa mostly the yellow kind is seen, and at times the red; the black variety seems to be absent in Europe.

During the researches I carried out in Ceylon in 1911 on the ætiology of *Trichomycosis axillaris* I came to the following conclusions.

The yellow variety, *Trichomycosis flava*, is caused by a fungus of the genus *Nocardia* (*Streptothrix*), which I called *Nocardia tenuis*. The black variety is caused by the same nocardia plus a black pigment-producing coccus, which lives in symbiosis therewith. This coccus I succeeded in growing; the colonies after a time become jet black. I called it *Micrococcus nigrescens*. The red variety is caused by the same *Nocardia* (*N. tenuis*) plus a red pigment-producing coccus, which I cultivated on various media. The coccus gives rise to red colonies and has been further investigated by Chalmers and O'Connell, who have paid me the compliment of giving it my name. Macfie has recently described a subvariety of Trichomycosis rubra: *T. fusca*.

Trichomycosis axillaris is an affection of little or no importance, but I have known European ladies in the tropics greatly distressed by it, as when they wear a low-necked dress the disfiguring red or black patches in the axillary regions are quite visible. It is a curious fact also that natives when affected with trichomycosis seem to regard it with disgust and readily seek treatment, and Chalmers and O'Connell have recently brought forward the suggestion that the general custom of shaving the axillary hair among certain native tribes may have originated in their profound dislike of this complaint. The treatment which I found most successful in Ceylon, apart, of course, from shaving, was dabbing the hair two or three times daily with a 1 per cent. alcoholic solution of formalin, with the application of sulphur ointment at night.

THE DERMATOMYCOSES SENSU STRICTO.

As regards the second group I propose touching briefly on the following: (1) tinea flava, (2) tinea nigra, (3) cryptococcosis epidermica, (4) acladiosis, (5) blastomycosis, (6) dhobie itch (tinea cruris), and (7) tinea imbricata.

Tinea Flava.

Ninety per cent. of the natives of the low country in Ceylon are more or less affected with this mycosis. It generally starts at a very early age, spreading slowly, and seldom, if ever, disappears completely. Variously shaped bright yellow spots are seen most commonly on the neck and chest, but any part of the body may be affected. In Singhalese poetical literature reference is often made to the tiny canary-coloured beauty spots present on the face of Ceylon young women. These spots, so much admired by native poets, who have coined a special poetical expression for them ("gomera"), are in reality merely minute patches of tinea flava, and are produced by the fungus I described under the name of *Malassezia tropica.* Sometimes all the patches of tinea flava coalesce together, giving rise to the diffuse form of the disease. Occasionally one is surprised to see a Singhalese or Tamil native with the face, chest, and trunk of much lighter colour than other natives; on closer examination it will often be found that this apparent lighter colour of the skin is merely due to a diffuse form of a very light variety of tinea flava. Tinea flava was considered to be, until recent years, identical with pityriasis versicolor of temperate climates. I separated it for the following reasons: (1) Tinea flava affects the face more frequently than any other region of the body; (2) it is extremely chronic, developing in early childhood and lasting for life; (3) it is most difficult to cure; (4) the fungus, which I called *Malassezia tropica,* seems to have almost a permanent disturbing action on the pigmentation processes of the skin, as even when the fungus has been destroyed the patches remain discoloured for a very long time, months and years, though they may in the end become again normally pigmented.

---

* Lectures I. and II. appeared in THE LANCET of April 17th (p. 847) and 24th (p. 895), 1920, respectively.

† See Castellani and Chalmers's Manual of Tropical Medicine, p. 2101.

The treatment, as I have already stated, is most difficult; turpentine is at times useful, and on covered parts of the body a chrysophanic ointment may be used.

Tinea Nigra.

This tropical dermatomycosis, fairly common in natives, is characterised by the presence of jet-black patches due to a fungus of the genus *Cladosporium* which I called *C. mansoni* in honour of Sir Patrick Manson. This fungus grows on glucose and maltose media, giving rise to black colonies. It may attack Europeans, as shown by the following case. A European medical man went to Burma for a pleasure trip. On coming back to Ceylon he noticed a roundish, very slightly elevated, black spot on the palm of his left hand. This spot slowly increased in size for two months, becoming the size of a sixpenny-piece. A single application of formalin made it disappear, but three months later it reappeared. A second application of formalin cured the condition permanently. From the patch, before treatment, cultures were made and a cladosporium isolated identical to that found in native cases.

Cryptococcosis Epidermica.

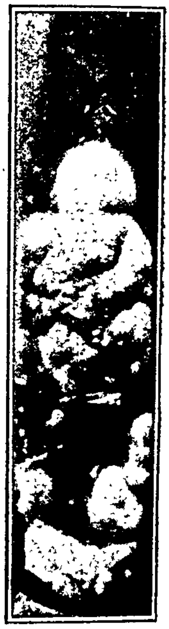
Many years ago I noticed on the skin of one of my bungalow servants several brownish patches, which looked very much like dirt. He told me, however, that they did not disappear on using soap. I made a scraping and saw that these patches consisted of a large number of budding cells which I believed to be saccharomyces. I found the same patches, not only in other natives, but also in Europeans, especially on the chest and arms, and called the condition saccharomycosis epidermica, which term I changed later into the more correct designation cryptococcosis epidermica. I did not succeed in growing the fungus. Recently Chalmers and others have confirmed my findings in the Sudan and North Africa, but the organism has not yet been cultivated. As to treatment, ordinary soap will not remove the patches; sand soap occasionally does. In obstinate cases the patches may be touched with an alcoholic solution of salicylic acid, and then a salicylic-sulphur ointment may be applied.

Acladiosis.

This dermatomycosis, described by me some years ago, is caused by a fungus of the genus *Acladium.* I grew the fungus from the lesions and sent cultures to Professor Pinoy, of the Paris Pasteur Institute, who kindly described it botanically, and honoured me by calling it after my name. I quote his description.

"The growth on artificial media (such as carrot, potato, glucose-agar) consists of many small roundish masses (Fig. 4) which later on may coalesce, and are covered by spiculated formations, giving them a prickly appearance, and consisting of erect, straight filaments, parallel to each other, or at times interlacing. These filaments are approximately 2 microns in diameter, and carry laterally pseudoconidia of variable shape, cylindriform, pyriform, or spherical, attenuated in size at their points of insertion. Most of these pseudoconidia are 4 microns in length, and have a breadth of 3 microns. This type of fructification recalls the type *Acladium,* described by Bodin in certain species of the genus *Trichophyton* (Malmeten, 1848). These pseudo-conidia become detached and then develop by sprouting, and mycelial filaments are formed. Certain filaments produce spherical chlamydospores arranged in small strings, as found in certain fungi of the genus *Fusarium.* These small chains of chlamydospores are very frequently terminal, the dimensions being variable —8-10 microns."

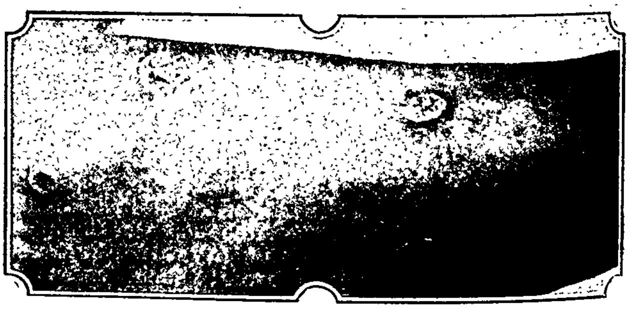
FIG. 4.



Growth of *Acladium castellanii,* Pinoy.

The affection is observed in Ceylon and the Federated Malay States, and during the war I found a case in Macedonia. Clinically, this dermatosis is very characteristic; in a well-marked case ulcerative lesions are present all over the body. The ulcers (Fig. 5) are roundish or oval, sharply defined, and with a red granulating fundus. There is often a fairly abundant purulent secretion, which dries up in thick bright yellow crusts covering the ulcers. Occasionally gummatous nodules and furuncle-like lesions are seen. The course of the disease is very long, and generally there is very little or no tendency to spontaneous cure. Potassium iodide when given in full doses is generally successful.

FIG. 5.



A case of acladiosis, showing characteristic roundish or oval ulcers, with sharply defined edges and a granulating fundus.

Blastomycosis.

The term blastomycosis is generally applied to affections due to fungi of the genera *Saccharomyces, Cryptococcus, Monilia, Oidium,* and *Coccidioides.* The clinical appearance may greatly vary; the cases I have seen may be classified into three principal groups: 1. The cutaneous type. 2. The muco-cutaneous type. 3. The gluteal blastomycosis.

1. *Cutaneous type.*—This type is characterised by verrucose patches with minute abscesses, is quite common in Ceylon and other tropical countries, and occasionally cases are seen also in temperate climates.

2. *Muco-cutaneous type.*—In this type the disease attacks not only the skin, but also the mucosæ, principally the oral mucosa and the pharynx, giving rise to numerous small verrucoid papillomatous or frambœsiform patches, which later may ulcerate. This type is common in South America, where it has been investigated by Splendore and others, but a very similar type is found also in Ceylon and other tropical and subtropical countries. Three weeks ago I saw a demobilised officer with lesions on the left angle of the

mouth, portions of the oral mucosa and of the tongue, which closely resembled a syphilide. The lesions had made their appearance in Egypt. The patient denied ever having contracted syphilis; moreover, in Egypt his blood was examined for a Wassermann three times, always with negative result. Notwithstanding the negative Wassermann the patient had several salvarsan injections and a long course of mercurial treatment without any benefit. In scrapings from the lesions I found a few yeast-like bodies, and culturally I have grown a fungus which resembles more a monilia than a saccharomyces or a cryptococcus. Under treatment by iodide of potassium the lesions are already very much better.

3. *Gluteal blastomycosis.*—This variety has been described by Kartulis in Egypt, and I have seen cases in Ceylon. The gluteal regions present a diffuse induration, and are riddled with numerous openings from which a thin purulent liquid exudes. Fungi of the genus *Saccharomyces* or *Monilia* are generally isolated from the pus.

As regards the prognosis, this is on the whole favourable in the cutaneous type provided an appropriate treatment is carried out—much less favourable in the muco-cutaneous and in the gluteal varieties. It must also be remembered that occasionally the organisms enter the general circulation and give rise to a pyæmia-like fever. Occasionally, in fact, one comes across cases of blastomycetic septicæmia without any skin lesion, and these cases, as a rule, terminate fatally.

Dhobie Itch.

I know of very few Europeans who, after one or two years residence in the tropics, have not contracted that most distressing and intensely itching condition of the inguino-scrotal region, which is known all over the East as dhobie itch, from the popular belief that it is acquired from underclothing and linen contaminated while being washed by the dhobie (native laundryman).

What is dhobie itch? It is in reality the old eczema marginatum described by Hebra. The history of the disease is briefly the following: About the middle of last century Hebra in Vienna described eczema marginatum of the inguinal regions. Later trichophyton-like fungi were found by various observers, and the condition was considered to be an inguinal localisation of tinea corporis, and the fungus was believed to be the same as *Trichophyton tonsurans*. In Ceylon in 1905, having found a fungus somewhat different from those observed in the usual types of tinea corporis, I suggested that the condition should be definitely separated from this disease. This fungus was characterised by its neglect to attack the hair or hair follicles and by the colour of its colonies on maltose or glucose-agar; these are of a peculiar lemon-yellow or orange-yellow colour. I called it *Tricophyton cruris*. In 1907 the same fungus was found by Sabouraud in France and called *Epidermophyton inguinale*. I sent cultures of the Ceylon strain both to Sabouraud and Pinoy, and they concluded that the French strains and the Ceylon strains were identical. According to the laws of nomenclature the correct name is *Epidermophyton cruris* and not *Epidermophyton inguinale*, as when a fungus is moved from one genus into another it does not lose its specific designation. As is well known, the generic designation of an organism may be changed, but the specific designation cannot be altered. In 1909 I found that certain cases of dhobie itch were due to a different epidermophyton (*E. rubrum*), and later I observed that a few cases were due to a true trichophyton (*T. nodoformans*). There are therefore three species of fungi which may give rise to dhobie itch—*E. cruris*, *E. rubrum*, and *T. nodoformans*.

1. *E. cruris*, as already stated, is characterised by its lemon-yellow or orange-yellow colonies.

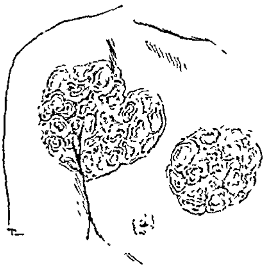
2. *E. rubrum*, which I described in 1909, is characterised by the deep-red pigmentation on glucose-agar.

3. *Tricophyton nodoformans* is characterised by the fact that the surface growth is white and powdery, while the submerged portion is of a brick-red colour, which, however, disappears after repeated transplantations. It is interesting to note that each species gives rise to a slightly different type of dhobie itch. *E. cruris* causes the common festooned variety identical with eczema marginatum of Hebra. *E. rubrum* causes an eczematoid-like variety; the edge is less raised and is made up of numerous small, close-set papules covered at times by minute bloody crusts. It has a great tendency to spread from the scroto-inguinal region to any part of the body and may, in fact, begin on practically any region. *T. nodoformans* induces an eruption with a very thick nodular margin, and the fungus may attack the hair follicles.

One word as to prognosis and treatment. An apparent cure is quite easily achieved, but a true cure is much more difficult. In patients who had dhobie itch in the tropics and have settled in Europe the infection may last for very many years, remaining dormant in winter, but breaking out regularly every summer; the best treatment consists, in my experience, in a salicylic-sulphur ointment and in very obstinate cases chrysophanic acid may be used.

Tinea Imbricata.

FIG. 6.



Tinea imbricata

This dermatomycosis, which is extremely common and of great practical importance in certain tropical countries, was first described by Dampier in his book, "A Voyage Round the World," in 1789. In Alibert's "Atlas of Skin Diseases," published in 1832, there is a very good illustration depicting the disease. In 1874 Tilbury Fox gave a description of the complaint under the term Tokelau ringworm. He detected in scales a filamentous fungus and considered it to be identical with the fungus of European ringworm. From that time discussion began and continued for many years on the subject, whether the disease was a separate entity or merely European ringworm modified by the different climatic conditions. The great majority of the European authorities, who, however, had no personal experience of the malady, were opposed to considering the disease a separate one, while the medical men practising in the tropics generally believed it to be a different affection from ringworm. Very valuable researches were carried out by McGregor in 1870 and Coniger in 1871, but Manson's researches in China during the period 1879–82 are by far the most important. He described the eruption in a masterly manner, and first introduced the very appropriate name of tinea imbricata. Moreover, he gave a very good microscopical description of the fungus, although, as might be expected, using the technique of that time, he did not succeed in cultivating it. He considered it to be a non-cultivable trichophyton for which Blanchard suggested the name *T. concentricum*. In recent years the malady has been generally considered to be a form of aspergillosis, especially after the well-known researches of Tribondeau, Wehner, and many other observers. Tribondeau described fructifications somewhat similar to those of an aspergillus and created for the fungus the genus *Lepidophyton*. Wehner described it as a true aspergillus (*Aspergillus tokelau*). I investigated the malady in Ceylon, and I think I may venture to say that I succeeded in proving that these aspergillus-like fungi have nothing to do with the disease, and that when they are present in the scales, as they often are, are merely saprophytes or contaminations. By using a special technique I succeeded in growing the fungi which I consider to be the true causative agents of the affection. I created for them the genus *Endodermophyton*, of which there are at least four species:

(1) *E. indicum*, (2) *E. tropicale*, (3) *E. concentricum*, and (4) *E. mansoni*. The fungi belonging to the genus *Endodermophyton* by their growth between the superficial and deep layers of the epidermis, form an interlacing felt of mycelium, which detaches the cornual and granular layers from the rete Malpighi. They do not invade the hair follicles and do not cause suppuration. Their cultures are similar to those of the genus *Achorion*. The difficulty in growing such fungi artificially is explained by the fact that they do not grow on solid media direct from the scales. These, after being treated with alcohol from five to ten minutes, must be placed in glucose-broth tubes, one scale in each tube. Most of the tubes become contaminated with bacteria, but in those which remain clear after a time (five to ten days) a few delicate short mycelial filaments will be seen originating from the scales. The growth slowly increases until after a few weeks it takes the appearance of a small white fluffy mass with a dark spot (the scale) in the centre. The fungi can then be transplanted on solid sugar media, on which they then will grow quite well and from which they can be subcultivated indefinitely. The species may be differentiated as follows:—

(1) *E. indicum*—glucose-agar cultures, deep orange or pinkish or red; white duvet often present.

(2) *E. tropicale*—glucose-agar cultures, amber-coloured; duvet absent or present only in very slight amount.

(3) *E. concentricum*—glucose-agar cultures after some weeks become black.

(4) *E. mansoni*—black pigmentation very rapid.

By inoculating cultures of the first two species I have succeeded in experimentally reproducing the disease in volunteer natives.

As to the predisposing causes as regards age, in my experience young adults are mostly affected, but children and very old people may contract it. Men are much more frequently infected than women. It is doubtful whether there is any racial disposition. In Fiji it is said, however, that the immigrant Tongas rarely contract the malady, while the indigenous Fijians are extremely prone to it. Some authorities believe that this relative immunity is due to the habit the Tongas have of anointing their skin.

As regards climatological influences, Manson has made the interesting observation that tinea imbricata is rife especially in those tropical countries and districts in which the climatic conditions are favourable for the growth of the coco-nut tree. I can confirm Manson's observations. In Ceylon tinea imbricata is not very common, but the cases one sees generally come from the coco-nut districts. There is no doubt that a hot, moist, equable climate is the most suitable for the fungi of tinea imbricata, as it is the most suitable for the growth of the coco-nut tree.

CLINICAL SYMPTOMS, DIAGNOSIS, AND PROGNOSIS OF TINEA IMBRICATA.

The development of the eruption is most interesting. At the very beginning one or several small roundish or oval dark-brown very small spots appear, generally on the arms, chest, or back. After a short time each brownish spot splits in the centre, and in this way a ring of flaky large scales attached at the periphery is formed; this scaly ring expands peripherally, and, while it does so, another brownish spot appears in the centre on the same site as the first brown spot; this new brown patch also breaks in the centre, and in this way a second ring scaly ring is formed, which expands towards the periphery inside the first ring; again in the centre a dark patch appears which splits, and a third ring is formed inside the second; and so on until a number of scaly rings develop. Sir Patrick Manson has aptly compared this development of concentric rings to the concentric ripples produced by a pebble thrown into a pool of water, and when the eruption starts from many points, as is often the case, owing to auto-inoculation, it is as if a shower of pebbles had fallen in the pond and many systems of spreading rings are produced which intersect each other. The scales are flaky, tissue-paper-like, large, up to half an inch in length, dry, and of a dirty-greyish or brownish colour. The fungus never invades the hair follicles nor, according to some authorities, the nails. I must say, however, that in my experience the nails are often affected, becoming discoloured and brittle, and this has also been Manson's experience. The eruption has not much effect on the general health of the patient, but the pruritus it induces is really terrible; the native patients refuse to do any work and remain in their compounds, where they can be seen squatting or lying down and scratching their bodies the whole day long. I have noticed that the itching is greatly increased by certain diets; for instance, the dry fish diet often given in Ceylon hospitals makes the pruritus absolutely unbearable.

The clinical picture of the disease is most characteristic, even when the eruption is of the diffuse type. The large, dry, tissue-paper-like scales, overlapping each other like tiles on a roof, are quite typical, but the diagnosis is certainly very difficult to the newly arrived European medical man, who may never have heard of the disease. On superficial examination the malady does not strike one as being of epiphytic origin, and the cases I generally had in the Colombo Clinic were often diagnosed by visitors—and naturally so—as cases of ichthyosis or of pityriasis rubra; it is, in fact, interesting to note that one of the many synonyms of this malady is "tropical ichthyosis." Of course, the microscopical examination of the scales will reveal the presence of an enormous number of mycelial filaments, and this will clear the diagnosis at once.

The disease, as I have already stated, has not at first a serious influence on the health of the patient, but the affection is chronic, and after a time the patient not rarely becomes anæmic, emaciated, and a nervous wreck owing to the continuous pruritus and loss of sleep. At any rate, the patient is not fit for any work, and this is of great practical importance, as it tends to decrease the labour force on low-country estates.

One word with regard to treatment. The disease never shows any tendency to spontaneous cure, and its treatment is most difficult, as every tropical practitioner knows. It is easy enough to obtain a temporary improvement and even a disappearance of the eruption; but as a rule a few days after discontinuing the treatment the eruption starts afresh.

In the Colombo Clinic I tried experimentally the most different drugs and ointments, and came to the conclusion that the best routine treatment is by resorcin dissolved in tr. benzoin. co. (resorcin ʒii, tr. benz. co. ad ℥i).

It is interesting to note that resorcin in ointment or in alcoholic solution has practically no action, and that tr. benzoin. co. alone has also practically no action, but when the resorcin is dissolved in the tincture good results are obtained.

PORTSMOUTH MATERNITY HOSPITAL.—A municipal maternity hospital was opened by the Mayor of Portsmouth on April 19th. A large and convenient house has been adapted for the purpose, providing accommodation for 12 patients. It is hoped eventually to have a much larger hospital. There is no intention of competing with existing nursing homes, as the new institution is for poor women who are unable to arrange for adequate help in their own homes. A fee of 30*s.* for a fortnight will be charged.

PSYCHO-NEUROLOGICAL SOCIETY, LANCASTER-GATE, W.—A clinical meeting was held on April 22nd, Dr. H. E. Davison being in the chair. The following cases were demonstrated. Dr. C. Worster-Drought: 1. Case of concussion of the spinal cord in the cervical region with Brown-Séquard syndrome and injury to the sixth and seventh left cervical nerve-roots. 2. Case of fracture-dislocation of the spine in the lower dorsal region with partial Brown-Séquard syndrome. 3. Case of proximal myopathy (Landouzy-Dejerine type). 4. Case of aphasia, agraphia, and alexia with right homonymous hemianopia in a man aged 30. 5. Case of early tabes dorsalis with double intention tremor. Dr. E. Danvers-Atkinson: Case of myotonia congenita. Dr. P. Bousfield: Case of motor aphasia and agraphia due to cerebral hæmorrhage in a young man.

THE PELLAGRA OUTBREAK IN EGYPT

I.—PELLAGRA AMONG OTTOMAN PRISONERS OF WAR.

BY A. DOUGLAS BIGLAND, B A CANTAB ,
M D LIVERP., M R C P. LOND ,
HONORARY PHYSICIAN, DAVID LEWIS NORTHERN HOSPITAL
LECTURER IN CLINICAL MEDICINE UNIVERSITY OF
LIVERPOOL HON CAPTAIN R A M C

IN a previous paper[1] I have detailed certain remarkable features occurring in Egypt among Ottoman prisoners of war during the summer, autumn, and winter of 1916. The appearances then shown I correlated under the heading "War Œdema" in order to bring this outbreak into line with others of a similar nature described in Europe during the recent war, and in other parts of the world at different times. In the paper referred to I showed that a few of the war œdema cases eventually developed symptoms of pellagra, as did also a considerable number of other prisoners who had not come under previous observation. In the winter 1916–17 the number of pellagra cases was large enough to warrant the use of the term "epidemic." This epidemic forms the subject of the present paper.

Incidence and Clinical Features of Pellagra.

Pellagra in this country is a comparatively rare disease. Small outbreaks have been described in asylums and similar institutions, while here and there in England and Scotland isolated cases have been described (Box,[2] Hammond,[3] Sambon,[4] and others). On the principle "whosoever hath not, from him shall be taken even that which he seemeth to have," the rarity of the disease increases its rarity because, contrary to what is usually taught, pellagra is extremely difficult to diagnose and often overlooked unless the possibility of its occurrence be kept in mind. It seems fitting, therefore, to increase the interest of this paper for English readers by the shortest possible outline of the disease as it is commonly seen.

Osler[5] defines pellagra as "a disorder of metabolism with periodical manifestations characterised by gastro intestinal disturbances, skin lesions, and a tendency to changes in the nervous system." This disease was first described by Cazal in Spain about 1762. The name then given to it was Mal de la Rosa In 1771 Frapolli, working in Italy, described the same condition under the name pellagra, or rough skin. Apparently pellagra first made its appearance in Europe about 1720, a date coinciding with that of the introduction of corn planting; this is a fact of some significance. Since then the disease has died out in some countries only to appear, or, perhaps, only to be recognised, in others It is now prevalent in Italy, Roumania, and the neighbouring States In Egypt Sandwith first reported cases in 1893, and it is now endemic in that country. In 1908 pellagra was first recognised in the Southern States of America as the same disease found in Italy. Stannus,[6] working in Nyasaland, reported cases there in 1910 And so the area of endemic pellagra grows, and it is more than probable that with increased knowledge of the disease this area will become still wider As regards the prevalence of pellagra in the countries named above, suffice it to say, that "there are probably 100,000 cases in Italy and 50,000 in Roumania" (Osler[7]). Also that in the last three months of 1914, in one State alone of the U.S A (Mississippi) there were reported 1845 cases (Niles[8]) Naturally, in such countries pellagra has become of supreme importance from a public health point of view.

The chief clinical features of pellagra can be summarised as follows.

It occurs chiefly, though not entirely, in the poorer classes, and for the most part in rural districts The disease begins in the spring or autumn, disappears after a short time, and reappears at a corresponding time the following year This periodicity may show itself for many years in succession Each attack tends to leave the patient in a worse condition than before Finally, these cases drift into asylums, develop some organic disease of the spinal cord, or die during one of the attacks, either from cachexia or from some intercurrent disease Of course, many cases may recover. The onset is characterised by general malaise with various morbid sensations referred to the digestive tract, soon followed by severe diarrhœa, often dysenteric in type, and most intractable Other derangements of the tract, such as sore mouth and tongue, anorexia, and vomiting, are usually associated with the diarrhœa The skin manifestations, without which the disease would never be recognised, soon make their appearance The rash begins as an ordinary sunburn on the exposed parts of the body, especially the hands and face, and its distribution usually shows the most perfect symmetry. At the onset of the rash burning is complained of in the areas affected Following the erythema appear marked pigmentation of the skin and desquamation In some cases vesicles and even bullæ may arise, a condition to which the name "wet pellagra" is given, always a sign of grave import Frequently the desquamating areas crack and deep fissuring of the surface may occur. After the attack is over the skin may return to normal, may hypertrophy, or may atrophy, leaving a condition resembling the skin of an old man in its papery texture and loss of elasticity.

Associated with the skin and gastro intestinal troubles there is great weakness and emaciation, together with nervous symptoms, the most common of which are great depression of spirits and psychasthenia An acute type of the disease is recognised, to which the term typhoid pellagra is applied

With this brief account of the history and clinical features of the disease, we may now turn to the specific outbreak under consideration, leaving the ætiology of pellagra to be dealt with subsequently. The work is divided into two periods: (1) from September, 1916, to June, 1917, after which I was unfortunately unable to carry out further investigations, and (2) during the winter of 1917–18 and spring of 1918, which I have studied from notes given to me by my friend and colleague, Dr J. I Enright.

The First Period of the Outbreak

This comprises work done on 64 cases. Firstly, should be cited a few facts bearing upon the ætiology of pellagra, a discussion of these being left to the section dealing with causation

Race —Turks, 46, Arabs, 8, Kurds, 5, unknown, 5

Native place —Scattered all over Turkey in Europe and Asia, Palestine, &c

Average period of war service —About 3 years

Place of capture —The Hedjaz, 41, Canal Zone, 18, Dardanelles, 4, Mesopotamia, 1

Date of capture —The Hedjaz cases were all captured at the fall of the three towns, Mecca, Jedda, and Taif, about June and July, 1916 The Dardanelles prisoners were captured in 1915, while those in the Canal Zone were captured for the most part in and about El Arish and Katia also in the summer of 1916 It will be seen that the prisoners from the Dardanelles had been in our hands nearly two years

Disposal of prisoners after capture —Some of these came direct to No 2 Prisoners of War Hospital, Cairo Others were sent to one of the two big prison camps in the Cairo district—viz, Heliopolis and Maadi Thirty two cases were analysed as regards their disposal Of these 14 were sent to Heliopolis Camp, 13 to Maadi camp, and 5 came direct to hospital

Incidence of pellagra —This point is extremely difficult to determine I carried out many and somewhat laborious inspections with a view to discovering, if possible, what percentage of Turkish prisoners at that time were pellagrins. Firstly I turned my attention to the camp at Heliopolis. Here I examined 3823 prisoners, of whom 24 were certainly pellagrins and 21 were doubtful. These inspections were performed in March, 1917. During the same month I visited the Red Crescent Hospital in Cairo. Here I examined 100 cases, of which not one showed any signs of pellagra. The Egyptian medical officer in charge told me that he had never seen a case in that hospital, though he admitted that during the summer of 1916 many cases had died of intractable diarrhœa.

In April, 1917, by the courtesy of the authorities, I was permitted to visit the Turkish women and children prisoners, numbering about 470. They had been captured in the Hedjaz during the summer of 1916 and all had suffered the horrors of siege. They ranged in social position from wives of superior officers to maidservants. I found no evidence of pellagra except that one case showed slightly suspicious signs.

It will be seen, therefore, that there were about 64 pellagrins in the winter 1916–17 out of some 4400 prisoners examined, a percentage of about 1·4.

The question whether this outbreak was merely a seasonal recurrence or the disease appearing for the first time is difficult to decide. In attempting to get a true history of his case from a Turk one feels almost sympathetic towards the gentlemen whose life-work it is to discover, if possible, the truth concerning our incomes. At best, in either case a good guess is the most that can be hoped for. In our country, too, a man's ignorance acts as a check upon his gift for telling lies, but with a Turk it is otherwise. Nevertheless, the statements of prisoners, in my opinion, are of some value when repeated cross-examinations are made at different times, and if when any discrepancies in the story arise the whole history is dismissed.

At the beginning of the outbreak I showed a few of the cases to one or two experienced observers, who gave it as their opinion that they were chronic pellagrins. Nevertheless, after examining many cases I am convinced that the majority were seen in their first attack. My reasons are as follows: (1) Out of the 64 cases 44 were positive that they had never had the condition before, 8 gave a doubtful history, 7 for one reason or another could give no history at all, while 5 were certain that they had had the condition once every year for some years. These statements were borne out by two Turkish officers and by an Armenian medical officer who had been attached to the Turkish Army. (2) All the cases had been soldiers engaged in an arduous campaign. Their average service was at least three years, some had been in the army seven years or longer, and chronic pellagrins could hardly support the strain of military life. (3) The fact that none of the women prisoners showed the disease, coupled with the fact that the disease is commoner in women than men, is very remarkable if pellagra had been endemic in the localities where they and the soldiers had lived. (4) The fact that two other epidemics occurred in Egypt during this war among communities that had not had the disease previously. I refer to the outbreaks at the Armenian Refugee Camp, Port Said, and at Cairo among German prisoners of war. (5) Chronic pellagrins usually show symptoms and signs pointing to organic disease of the nervous system. Organic nerve disease was extremely rare in this outbreak.

At this point I should like briefly to quote two cases, the first in favour of my view and the second one of the five cases which gave a clear history of previous attacks.

CASE 1.—Pte. S. K., 27 years of age. An Arab; previous occupation—butcher. Six years army service, all in the Hedjaz. Taken prisoner in Jedda, June, 1916. Three days after capture began to have diarrhœa, followed by malaria; admitted to hospital at Cairo August 8th, 1916, with malignant malaria and very severe anæmia. Marked œdema appeared, which lasted two months, and the patient nearly died. He gradually recovered and was discharged perfectly fit on Jan. 22nd, 1917. In February, 1917, I found the man at Heliopolis camp with a typical pellagrous rash on hands and face. This patient affirmed that he had never had the disease before, and a sergeant who had been in the same company with him for three years confirmed the story. This sergeant was chief Turkish orderly in the pellagra ward and, besides having a good knowledge of the disease, was an extremely intelligent man.

CASE 2.—Pte. H. A., 27 years of age. A Kurd; previous occupation—fellah. Three years service, all in the Hedjaz. This man states that he has had the same condition for the last eight years at this time of year. The condition lasts about two months, the attack beginning with itching of the skin and then the hands become a "blood-coloured red." After about seven days the skin fissures and cracks. Diarrhœa with blood and mucus is present at these times, also headache, night blindness, indigestion, pyrosis, nausea, and vomiting. This is a most perfect history of the disease, and he repeated it on more than one occasion without a slip. For eight years he had been getting thinner and weaker. This attack was the last, for he died on March 26th, 1917.

The onset of the attack.—Most of the cases had suffered from diarrhœa for a long period before the diagnosis of pellagra was made. It is only when the rash appears that the nature of the condition is made clear. The month of January, 1917, as the following table shows, was the most favourable time for the appearance of the rash.

1916		1917				
Nov.	Dec.	Jan.	Feb.	March	April	Unknown.
1	5	23	12	10	4	9

It may be interesting to note here the incidence of other diseases previous to the appearance of the rash. The figures are as follows: Malaria only, 1; dysentery only, 25; malaria and dysentery together, 8; neither malaria nor dysentery, 30.

The gastro-intestinal system.—The tongue in pellagra, as is well known, shows typical features, the edges and tip are bright red, while the papillæ stand out as little red dots. Later atrophy of the mucous membrane may occur. This condition was noted in 29 of the 64 cases. Burning in the mouth and especially in the œsophagus were common complaints, though the cause of the latter is obscure. The appetite was, as a rule, poor, but how much of this symptom was due to pellagra and how much to the extraordinary outlook of the Turk upon questions of disease and death it is impossible to say.

Diarrhœa, of course, was a prominent symptom, and it occurred constantly in the severe cases, usually with blood and mucus, though in the mild cases I was surprised to note its absence. Out of the 64 cases 24 had dysentery, 19 had diarrhœa without blood or mucus, and 21 had no diarrhœa at all.

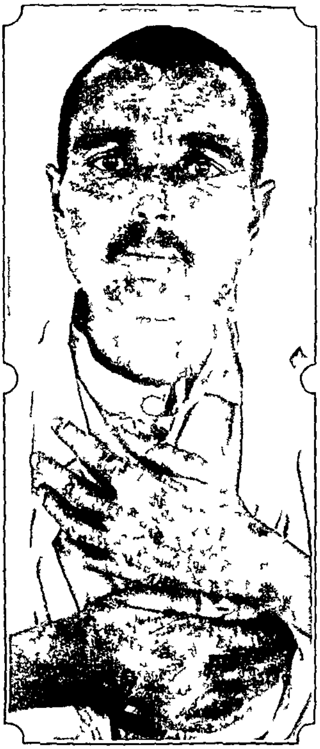
One very interesting feature remarked was the frequency of fæcal incontinence, the urine being held normally. This at first was accounted for by finding post mortem marked ulceration of the rectum extending even down to and involving the anal ring. That this is not the only explanation is proved by three cases, all showing incontinence, of which two showed normal intestines post mortem, while the third did not die and never had any blood in the motions.

Dr. Enright[9] has described a parotitis in pellagra. I noted only one case in my series and here the condition was unilateral.

Many observers have remarked how often pellagra is associated with intestinal parasites, especially the *Ankylostoma duodenale*. This parasite was never found in the post-mortem examinations, though always looked for, nor were its ova ever found in the stools. Dr. Manson-Bahr and myself made careful examinations of the stools in 39 cases in search of the ova of common parasites, our results being as follows: 28 nil, 2 lamblia cysts, 2 ascaris, 3 *Amœba coli* cysts, 1 *Tænia solium*, 2 *Trichocephalus dispar*, 1 *Oxyuris vermicularis*.

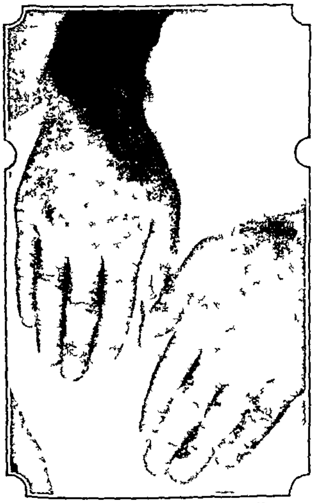
Skin lesions.—There can be no doubt but that the sun's rays play an important part in the production of the pellagra rash. This is evidenced by the frequency of the skin manifestations on the exposed areas, my figures for which are as follows: Out of the 64 cases 63 showed the rash on the hands, 30 on the feet (in the exposed part of the dorsum between the distal end of

FIG 1



Typical severe pellagrous eruption on face and hands Notice the perfect symmetry of the rash and the fissuring of the hands

FIG 2



To show desquamation of skin in pellagra

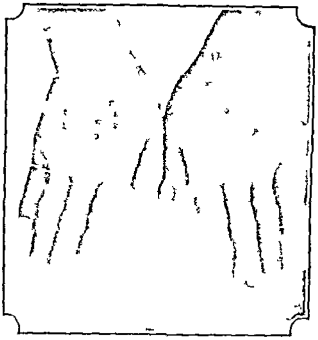
the *turned up* trouser and the proximal end of the Turkish slipper) (see Fig 4), 22 on the face, 16 on the neck 8 on the chest (where exposed), and 3 on the ears Bilateral symmetry was usually perfect

Though the sun's rays play an important part in the production of the rash, I was never able to make any skin changes appear at will, even after repeated trials with one arm bare or wearing a glove on one hand only I cannot account for this failure Pressure areas also show definite changes in the overlying skin, which becomes rough, thick, and deeply pigmented The commonest situations for these changes are the external malleoli, sacrum, knees, and elbows Thirty five of the cases showed these signs, and they lasted long after all other typical appearances had disappeared Many of the cases showed a curious fine branny desquamation over the body generally, even in those situations where no rash had been present One case showed a pellagrous eruption on the scrotum—interesting because this was the site where Goldberger's artificially produced pellagrins first showed the rash [10]

Lastly, under this heading I wish to describe a condition to which only one reference could be found (Marie [11]) In eight of the cases there was noted a peculiar seborrhœic condition, chiefly round the alæ nasi, sometimes scattered over the whole face (see Fig 5) In appearance this condition was likened to small sulphur granules raised above the surface of the skin This was not found among non pellagrous Turks

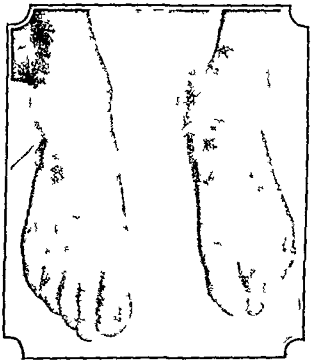
Nervous system—Of the 64 cases 50 were subjected to a routine neurological examination It was found that while hysterical stigmata were common, organic disease of the nervous system only occurred in 4 cases One became demented, one developed delusional insanity two showed evidence of pyramidal tract lesions, associated in one case with double optic neuritis going on to atrophy No evidences of central neuritis were forthcoming A slow lateral nystagmus was noted in a few cases, while night blindness was complained of only once Various paræsthesiæ, together with tenderness in the muscles of the back and legs, were frequent

FIG 3



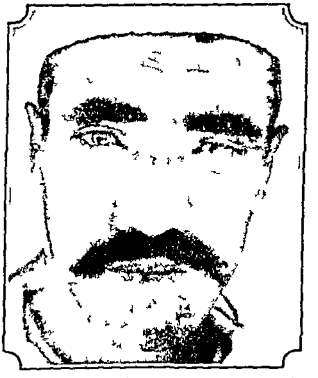
Showing more chronic stage of the rash—viz pigmentation and thickening of the epidermis

FIG 4



The rash in pellagra on dorsum of feet Notice that the rash is only seen on the area exposed between distal end of trouser and proximal end of Turkish slipper

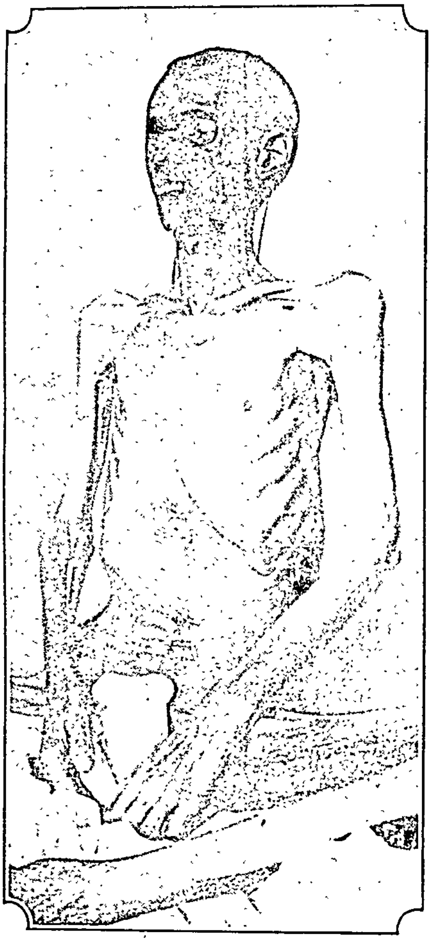
FIG 5



Showing a somewhat rare skin change in pellagra—viz seborrhœa of the face especially round the nose

Without doubt the most distinctive sign was a profound melancholy of a temporary nature associated with a mask-like face, and even sometimes with a Parkinsonian gait. Vertigo and sleeplessness were troublesome symptoms. Emaciation was very marked in the fatal cases (see Fig. 6).

FIG. 6.



Photograph taken post mortem to show the great emaciation in pellagra.

Œdema occurring in pellagrins.—From a study of the literature it appears that œdema in pellagra is a symptom of the greatest rarity. I can only find one reference bearing on the subject—Külz.[12] As will be seen, however, from the following extracts from my recent paper on war œdema,[1] this condition was quite common in the epidemic now under discussion.

Incidence of œdema.—Œdema observed, 36; œdema in history only, 7; no œdema observed or mentioned in history, 21.

Extent of œdema in these 36 cases.—General anasarca, 7; legs and feet, 29; legs and face, 0; legs and sacral region, 0.

Time relation between onset of œdema and pellagrous rash.—Total pellagrins with œdema, 43; œdema before rash, 24; synchronous with rash, 15; œdema after rash, 4.

The blood in pellagra.—Careful blood counts were made upon 25 cases: R.B.C. 1,500,000 and below, 2; R.B.C. up to 2,500,000, 2; R.B.C. up to 3,500,000, 9; R.B.C. above 3,500,000, 12. The absolute leucocyte count in the majority approximated to normal, but a relative lymphocytosis was present in some. Of the 25 cases, 17 had a lymphocytosis of over 30 per cent. and 10 over 40 per cent. The highest count was 60 per cent. Eosinophile cells were on the average 1·5 per cent., the highest count being 6 per cent. The colour index in 14 of the cases was normal, in 5 below 1, and in 6 higher than 1. For considerable help in the above counts I am indebted to Dr. Manson-Bahr.

The urine in pellagra.—No albumin, blood, sugar, or casts were found in 44 out of 46 cases examined. Indican was looked for in 37 cases. Two methods were used: (1) Calcium hypochlorite, (2) hydrochloric acid and chlorate of potash. In 24 the reaction was present but slight, in 5 it was marked, and in 4 it was absent. Variations were shown upon successive examinations. In view of the marked wasting I tried tests for acetone (both iodoform and nitro-prusside reactions) and diacetic acid (ferric chloride). Neither of these substances was ever found.

Blood pressure.—The resemblance of pellagra to Addison's disease suggested these examinations. In some of the cases very low readings were found, especially just before death. The lowest readings of systolic pressure in 3 moribund cases were 78, 80, and 86 respectively. Both the palpation and auscultatory methods were used.

Progress of the cases.—Of the 64 cases 26 died, 24 were discharged perfectly well, and 14 were still in hospital when I left at the end of June, 1914. It is interesting here to note that surgical cases with wounds show great difficulty in healing and fractured bones complicated with pellagra would not unite. So marked were these facts that after further experience severe limb injuries with pellagra were treated by immediate amputation.

Post-mortem Findings.

Of the 26 cases that died post-mortem examinations were performed in 24. For 14 of these I am indebted to Dr. Manson-Bahr. The results can be briefly summarised as follows.

Intestines.—Nineteen showed severe ulceration of a bacillary dysenteric type. Three presented a curious condition of small, scattered submucous hæmorrhages throughout the large intestine. In two cases the intestines were normal. In none was the ankylostoma found and in none was there any thinning of the intestinal wall so often described.

Liver.—Average weight 41 oz. Seven showed fatty changes. In one there was a large hydatid cyst.

Spleen.—Average weight 9 oz. Eleven showed perisplenitis (in one this was cartilaginous).

Kidneys.—Normal except in three cases, which showed miliary abscesses (*B. coli*).

Suprarenals.—Normal in all but one case, where there was hæmorrhage into both organs; in this case each gland weighed ½ oz.

Thyroid and *pancreas* normal.

Heart.—Singularly small. Usual weight about 5–6 oz.

Lungs.—Hilum phthisis, 3 cases; advanced phthisis with cavity formation, 1 case; tuberculous bronchial glands, 2 cases; pneumonia, 2 cases.

Brain and spinal cord.—These organs were examined in 12 cases. Of these, 9 showed a peculiar brown pigmentation around the medulla, most marked on the anterior surface. Dr. Warnock, director of the asylum at Abbassia, stated that this curious condition is very common in pellagra. Another feature that I have not seen described elsewhere was a gelatinous condition of the choroid plexuses resembling frog spawn. This was noticed in three of the cases. In one case the brain was œdematous and in four the amount of cerebro-spinal fluid was increased.

Dr. Manson-Bahr examined microscopic sections of all the organs except the brain and spinal cord. Unfortunately, we had no facilities for neurological research at that time. The intestines showed the usual changes associated with bacillary dysentery, while the other organs appeared for the most part normal. Dr. Manson-Bahr reports that he found almost constantly in the suprarenals a fatty degeneration of the cortex.

Treatment.

The therapeutics of pellagra is unfortunately very limited. In these cases I tried three lines of treatment.

(1) Arsenic, given in the form of Fowler's solution. The initial dose was 3 m. three times daily, increasing by 1 m. every other day up to 12 m. t.d.s. At this dosage all the 16 cases showed marked increase in diarrhœa. Two cases received 14 m. t.d.s., but they, too, then fell out owing to diarrhœa. An arsenic-free interval was ordered and then the treatment was begun again. This time, even when the dosage reached m. 4 t.d.s., diarrhœa became worse and the treatment was stopped. My experience was that arsenic is contraindicated in the acute stages of the disease.

(2) On the assumption that there was suprarenal inadequacy in pellagra adrenalin was tried in the absence of preparations of the whole gland. Hypodermic injections of 5 m. of a 1/1000 solution were given t.d.s. My opinion is that benefit was derived from this drug in many of the cases.

(3) Finally, on the assumption that pellagra is a food-deficiency disease a liberal increase in diet was tried without drugs. The ordinary hospital diet was altered to the following:—Breakfast: bread and milk (English

bread, milk 1 pint) with sugar, and one egg. At 10.30 A.M. one egg in ¼ pint of milk. Dinner: Vegetable soup, lean meat or chicken (½–¾ lb.), rice and vegetables sometimes, potatoes, and English bread. Supper: Bread and milk (English bread, milk ½ pint) and sugar and one egg. At 8 P.M.: One egg in ¼ pint of milk. Cheese with meals occasionally. I gave orders that these quantities might be exceeded, but that never less than 2 pints of milk, four eggs, and half to three-quarters of a pound of meat a day should be given. When severe diarrhœa was present the rice and vegetables were excluded, but not the soup; otherwise the diet remained the same. On May 1st, 1917, 10 bad cases of pellagra were placed on the above diet; 2 of these died, so 2 of the control cases were added. Observations of weight, the only sure criterion of progress in pellagra, were made at weekly intervals up to June 21st, 1917, when owing to illness I had to relinquish the work.

Leaving out of account the 2 cases which died, increase in weight was noted in 7 out of the 10 cases; 2 remained the same and 1 decreased by 19 lb. Of the 7 cases which gained weight the increase in seven weeks was as follows: 6 lb., 9 lb., 17 lb., 18 lb., 19 lb., 23 lb., 23 lb. Sixteen other cases were taken as controls; these were kept on the ordinary full diet of the hospital —viz., per diem: native bread, 937 g.; beef, 115 g.; vegetables, 120 g.; rice, 115 g.; milk, 200 g.; fat, 20 g.; sugar, 200 g.; salt, 15 g.; black pepper, 3 g.; onions, 20 g.; tomatoes, 10 g. Of these 16 cases, 7 were pellagrins, 9 were not. The 7 pellagrins showed slight changes only in weight except one, who gained 13 lb. in five weeks. The 9 non-pellagrins gained weight slightly on the average, the highest gain being 8 lb. It is clear, therefore, that the increase in diet was decidedly beneficial as a therapeutic measure.

Experimental Work.

Blood cultures.—Seven cases of pellagra with the rash at its height were studied by Dr. Manson-Bahr and myself. The blood was collected in the usual way and cultivated according to the following five methods. (1) N.N.N. medium for protozoa (Manson)[13]; (2) glucose broth; (3) bile; (4) blood serum; (5) anaerobic. The results were disappointing. Most of the cultures remained sterile throughout, while others were obviously contaminated by the dust so difficult to avoid in the Egyptian climate in summer. No trace of Tizzoni's strepto-bacillus[14 15] was discovered, nor did we notice any abnormal fluorescene of the blood serum.[16]

Examination of fæces for strepto-bacillus of Tizzoni.—This author[14 15] states that if pellagrous stools are heated at 80° C. for one hour most of the organisms are destroyed and a strepto-bacillus can be isolated. Like most other observers (Perroncito[17] &c.), I could find no such micro-organism.

Complement-fixation phenomena in pellagra.—For this section I am again indebted to Dr. Manson-Bahr. Attempts have been made by Cesa-Biancha,[18] Ormsby,[19] and others to discover a reaction similar to the Wassermann test in syphilis. So far the results have been negative. Firstly, 11 pellagrous sera were examined by the Wassermann test for syphilis and all found completely negative. Next, various antigens were made from the organs of pellagrous post-mortems—viz., thyroid, suprarenal, liver, spleen, kidney. The antigens were prepared in different ways: (1) thyroid, 10 per cent. in 70 per cent. alcohol; (2) suprarenal, 5 per cent. in 70 per cent. alcohol; (3) spleen, 5 per cent. in 70 per cent. alcohol; (4) liver, 5 per cent. in 70 per cent. alcohol; (5) kidney, 5 per cent. in 70 per cent. alcohol. (Also varying strengths of these antigen solutions.) The antigens were prepared by macerating the organs and leaving them to dry in the sun in sterile Petri dishes. Then the alcohol was added and extraction allowed to go on for varying periods, usually about three days. Saline extracts were also made as follows: Immediately after death the organs were macerated in 5–6 times their volumes of normal saline plus 5 per cent. phenol. These were then left seven days in the incubator, being stirred repeatedly. Finally, the solutions were filtered into sterile test-tubes. Many experiments were made using these antigens upon the sera of pellagrins, but no complement-fixation was observed.

Inoculation of rabbits with pellagrous sera.—In 1914 Harris[20] stated that he had produced pellagra in a monkey by injecting a Berkefeld filtrate derived from human pellagrous organs. Lavinder, Francis, Grimm, and Lorenz[21] repeated the experiment on many monkeys with only one doubtfully positive result. Dearman[22] claimed that after injecting rabbits with pellagrous blood in nine days symptoms developed, and in 23 days erythema, desquamation, and pigmentation of the skin followed.

We attempted to repeat Dearman's experiments, though at that time his work was unknown to us. Eight rabbits were procured, but seven died before the work could be started. The remaining rabbit received four intravenous injections of 2 c.cm. of pellagrous serum at two-day intervals. No ill-effects were noted up to its death from foot rot.

Diagnostic uses of maize extracts.—Much work has been done on this subject, using extracts of good and bad maize. The results so far are contradictory (Ormsby,[19] Raubitschek,[23] Rondini,[24] Finita and Novello,[25] Cesa-Bianchi,[18] Volpino[26]). I procured large quantities of maize, but all my efforts to render it bad failed. Extracts from good maize were prepared, but unfortunately this part of the work remained uncompleted.

The Second Period of the Outbreak.

For a description of this period I have used the notes which Dr. J. I. Enright has so kindly placed at my disposal. During this time 118 cases of pellagra were examined while in hospital. The great majority of them were Turks, six were Albanians, two Arabs, and one Greek. I was interested to find in reading over these notes records of two only of my old cases from the previous outbreak; both of these died. It is not my intention to give a detailed description of these cases, and I will only mention some of the more important features. Out of 118 cases:—

Gastro-intestinal system.—Diarrhœa with blood, 53, diarrhœa without blood, 33; no diarrhœa, 32.

The rash.—Hands, 114 (the remaining four cases had marked atrophy of the skin of the hands); face, 25; neck, 23; feet, 81; pressure areas, 30.

Tongue showed the usual changes in the majority of the cases.

Nervous system.—Apparently none of the cases showed signs of organic nerve disease.

Œdema.—The total number of cases showing this symptom was 38. The distribution was as follows. extremities, 32; anasarca, 11; serous cavities, 22.

Urine.—57 cases were examined. Albumin is noted as being present in considerable amount in 26 and in a trace only in 7.

Blood.—42 cases were examined both as regards absolute and differential counts. The results were practically the same as those found by other observers, except that the lymphocytosis was not so frequent or so high.

Besides the usual diseases common to a subtropical climate phthisis was noted as being present clinically in 17. The severity of this outbreak can readily be imagined when we see that 92 out of the 118 cases died.

Post-mortems.

Dr. Enright gave me notes of 32 *post-mortem* examinations from which I have extracted the following points:—

Lungs.—Phthisis, 10; pneumonia, 3; pleural effusion, 3; tuberculous bronchial glands, 2; bronchiectasis, 1 (with amyloid liver and spleen).

Heart.—Average weight 7 oz. Normal, except pericarditis, 2; mitral stenosis, 2.

Spleen.—Average weight 8 oz. (the largest 16 oz., the smallest 2 oz.; 8 showed perisplenitis).

Liver.—Average weight 40 oz.; fatty changes were noted in 13 and perihepatitis in 2.

Kidneys.—Normal, except for 3 which showed subacute nephritis and 1 which had tubercular lesions.

Intestines.—Dysenteric ulceration was present in 21 cases.

This concludes the second period. The next period is dealt with by the Pellagra Commission which investigated the disease among the prisoners of war from October, 1918, to December, 1918.

Remarks on the Causation of Pellagra.

For some years I have thought that the only way to discover the cause of a disease like pellagra was to make, as it were, an armchair study of all the cases the world over. The question will then resolve itself into a review of the similarities and dissimilarities presented by the various outbreaks, with the hope that in the end the search may reveal a factor common to all.

Consider the following instances: a woman in the Orkney Isles, an Egyptian peasant, a small boy in London, a native in Nyasaland, a lunatic in one of our London asylums, a governess in a well-to-do family in the Southern States of America. All these cases suffer from pellagra. What is the common factor here? It cannot be colloidal silica in the water they drink (Alessandrini[27]). Is it the bite of a fly? (Sambon[28] and others). What fly, except the common house-fly, is found in all these places? If the house-fly be the cause, why is the disease so rare where the fly is so common? And so on through all the various ætiological theories we go, finding that none will fit all the cases except two: (1) that the disease is due to the absence of something, possibly in the diet; (2) that it is due to the presence of something, possibly a toxin.

A consideration of the present outbreak, together with the fact that the German prisoners of war in Egypt showed the disease, must also bring us to the same two conclusions. Here you have two armies fighting over the same ground, exposed to the same climate and privations, and coming of a very similar race, the British and the Germans. The Germans develop pellagra, while the British do not. Three possible differences exist: (1) That the Germans were fighting alongside the Turks, some of whom were pellagrous at the time. It must not be forgotten, however, that with our army was the Egyptian Labour Corps, and pellagra is endemic is Egypt. This difference, then, is excluded. (2) That the Germans were suffering from the absence of something, probably in the diet, which our army possessed. (3) The Germans came under the influence of a toxin not affecting our army.

The Three Grades of Pellagra.

Before discussing these two possibilities, I wish to make clear two views which I hold regarding pellagra itself.

(1) It must not be thought that the disease is necessarily a clinical entity in the sense that it has one definite cause only in its production. It may be rather of the nature of a syndrome, for which more than one factor may be responsible. The lesson of beri-beri, however, teaches clearly that seemingly opposed views may in reality be one and the same. This disease at first was said to be due to eating polished rice. So it was. Others said it could not be due to eating rice, because those who did not eat rice were attacked by a similar disease. They also were right. The vitamine theory ultimately showed that both views were correct. Thus it may be with pellagra.

(2) The second point that I wish to emphasise is the extreme variability in the severity of the disease. This is acknowledged on all sides by saying the disease is mild, severe, &c. But I would point out there may be something more than this. I first realised that this was so after many discussions with Dr. W. H. Wilson, of the Physiological Department of the Kasr-el-Aini Medical School, Cairo. I wish to take this opportunity of thanking him for the insight he gave me into the ætiology of pellagra and to state that many of the views here put forward are due to his influence, as will be obvious from the Egyptian Pellagra Commission Report. After much thought upon Dr. Wilson's arguments I have come to the conclusion that pellagra is a syndome of three grades, with perhaps a different ætiology. Grade I. is exemplified by a small Egyptian gardener boy in the employ of Dr. Wilson. This boy developed pellagra and he was cured almost immediately by the simple device of adding one egg per diem to his diet. Contrast this with the sweetshop assistant who is allowed to eat sweets ad nauseam till she is cured of the craving. She develops glycosuria, which is immediately cured by stopping the excessive sugar intake. Grade II. is present when the pellagrin can be saved only by relentless over-feeding. The lost balance is regained and maintained in the same way as by carefully dieting an elderly diabetic we may prolong his life for many years. Grade III. is the stage when the balance is lost completely and nothing can re-establish it, as in the young diabetic. It is clear that these three grades of diabetes probably have a different ætiology. Is it possible that the same reasoning may be applied to the syndrome called pellagra?

With these possibilities in mind, let us discuss the two views concerning the ætiology of the disease.

Pellagra as a Deficiency Disease.

Firstly, then, pellagra may be due to the absence of something in the diet. Strambio in 1786 began the maize theory of the disease, which has adherents to this day. It has certainly been shown that those who have never eaten maize contract pellagra, but numerous observers still fail to read the lesson of beri-beri. There is evidence to show that there is something lacking in the dietary of those eating maize, but it is not true to say that either good or bad maize is the cause of pellagra. What is the substance lacking in such a diet? The work of Goldberger[10] is of enormous importance in the answering of this question. He persuaded a squad of 11 convicts to subject themselves to a certain dietary for a given period with the reward of a free pardon. Goldberger then instituted a diet which in essence was lacking in fresh animal protein, with the result that within five months 6 of the 11 volunteers developed pellagra. Not content with this, Goldberger then performed the converse experiment. An orphanage was chosen in which every year pellagra made its appearance. The diet of the inmates was then largely increased, chiefly in respect of fresh animal protein, and in the following season the disease was practically absent. I can find no record of the after-history of the six pellagrous convicts, but it seems that they belonged to Grade I. of the disease. The orphans, however, may have been Grade II. cases.

Further evidence regarding diet deficiencies and pellagra is furnished by the interesting observations of Külz,[12] a German medical officer, who himself contracted the disease during the war while on service in Roumania. This officer states that the German bread contained 20 per cent. of maize, and this bread, he claims, was the cause of his illness. The first symptoms were referred to the digestive tract, then followed œdema of the legs, and, finally, a pellagrous eruption. He was then invalided home and was perfectly well in three weeks. However, every time he ate army bread the œdema again appeared, and he seems confident that had he continued to eat it pellagra also would have reappeared. The exact order of symptoms here depicted was that noted among the Turks—namely, first diarrhœa, then œdema, then the rash.

Was there any food deficiency among the Turks? For the dietetic facts here quoted I am indebted to the report of the Egyptian Pellagra Commission. In this report Dr. Wilson introduces a comparatively new idea to which the name "Biological Value of Protein" is given. It is well known that though, outwardly, vegetable and meat protein are similar, actually meat protein is very much more readily assimilated than the vegetable variety. It is this assimilability of protein which constitutes its biological value. Dr. Wilson reports that "Pellagra occurs or does not occur according as that value was less or more than 40 g. per diem." The pre-capture diets of the Turks on the Sinai front showed 30·4 as the biological value of the protein; in 1918, on the Palestine front, it fell to 21, and we may be sure that it was as low or even lower in the Hedjaz. The diets for labour prisoners showed a value of 48·7, amended later to 53·8, and for non-labour prisoners 39 1, later amended to 44·6 The cases that I have described were non labour prisoners and received the non-amended diet. The interned women prisoners' diet showed a biological value of 41·9, and it will be remembered that they did not contract pellagra.

It is clear, therefore, that the Turks before capture were suffering from food deficiency and that for some time after capture they were subject to a diet not very much better. This may account for the fact that some were pellagrous when captured and others developed the disease after capture Even if it be asserted that all the prisoners were really chronic pellagrins, it appears that the diets supplied in our camps were not sufficient to inhibit recurrences

Sufficient has been said to show that there is a definite connexion between food deficiency and pellagra Sufficient also is the evidence that the Turks were subject to a food deficiency and that correcting this error caused great improvement in their condition. It only remains to draw the conclusion that the diet omissions were the cause of the disease

This evidence is enough to account for the majority of pellagra outbreaks. But here and there cases arise which have been in no way subject to any food deficiency. Such an outbreak of pellagra has been recorded by Dr. Enright among German prisoners of war in Cairo after capture. These cases both before and after capture were very well fed, the biological protein value of the post capture diet being at the beginning 49 4 and later being raised to 58·3 How can such cases be accounted for?

The Toxin Hypothesis.

This brings me to the second supposition regarding the ætiology of pellagra—viz., the presence of some toxic substance. I would suggest that such a toxin is present in these cases, and that it acts upon the intestines or the contents thereof in such a way that protein is not assimilated as it ought to be A man receives, for example, protein of biological value 58, but owing to toxin influences, the figure 30 may represent the amount actually assimilated. Accordingly he becomes pellagrous, not because there is an error in his diet, but because there is an error in himself. The end result is the same—protein starvation In my opinion, therefore, cases of pellagra occurring amongst those who have always had good food and plenty of it, do *not* negative the theory that pellagra is a food deficiency disease Perhaps, also, there is some such ætiological difference in the three grades of the disease

It only remains to discuss what is the nature of this hypothetical toxic substance. It must enter the body from without It cannot be the result of a metabolic error, because the disease occurs in epidemics It is difficult to imagine, for example, an epidemic of diabetes. It cannot be carried by the bite of an insect for reasons already stated It has nothing to do with malaria or dysentery because pellagra was unknown in our troops who suffered from both diseases It may be contained in ingested material, but, if it is, it must be something common to the whole world since cases occur in such different localities Its probable habitat is the digestive tract, as evidenced by the gastro intestinal symptoms which usually appear first, and the indicanuria, and by the fact that protein is found in the stools in abnormal amounts It may be, however, that this toxic substance makes its effect by attacking the endocrine organs, especially the suprarenals. The similarities of pellagra to Addison's disease are too obvious to detail. The toxin is apparently of the nature of a virus, since the nervous changes show unmistakable evidence of degeneration rather than of inflammation. That this substance is not transmissible is shown by two facts. (1) That no attendant on pellagrins has ever contracted the disease, and (2) the heroic experiments of Goldberger,[29] in which fæces, urine, scales from the skin, and all manner of horrible matters arising from pellagrins were eaten by volunteers with no evil results, even after injections and inoculation on mucous surfaces.

Conclusion.

I claim that there is some evidence to show that pellagra is a syndrome which occurs most often in the under-fed, using the expression in its scientific sense, and sometimes in the well-fed. I have also tried to show how this syndrome may vary in character, according as the food deficiency is from without or from within. I state emphatically that just as perilobular cirrhosis of the liver may occur in those who have drunk spirits to excess and in those who have never had a drop of alcohol in their lives, due, as it is supposed, to some derangement of the intestine, so may pellagra occur in the under fed and in the well-fed for a similar reason.

To show that I am fully aware of my presumption in trying to say anything new about pellagra, I will mention in conclusion a quotation which may be found in one of the late Dr. Sandwith's papers: "The field of pellagrous ætiology has been the playground of fledglings, whose intellectual judgment is befuddled because they have no real comprehension of the fundamental question, and therefore attempt to introduce into the ætiology of pellagra all sorts of things from bald banalities to the most wonderful fantasies"

My thanks are due to the authorities for the facilities they gave for this work, and especially would I mention again Dr. Manson-Bahr, whose energy and scientific devotion have inspired me to renewed efforts.

THE LATE DR. W. ALLEN.—William Allen, M D., M Ch & L M R U I, who died recently at his residence, Derwent House, Shotley Bridge, aged 63, was a student of Queen's College, Galway, and a graduate and gold medalist of the University of Ireland He qualified in 1877 and was for a time senior demonstrator of anatomy in the University of Glasgow. Some 36 years ago he went to Leadgate in Yorkshire, where he was medical superintendent of the infectious hospital and medical officer of health to the urban district council, as well as medical officer of health to the Benfield side urban district council Later he removed to Shotley Bridge where he built up an extensive practice, and where he will be much missed

INTRA-CARDIAC PRESSURE AS A STANDARD IN CARDIOTHERAPY.

BY I. HARRIS, M.D.,
HONORARY PHYSICIAN, CARDIOGRAPHIC DEPARTMENT, DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL.

IN spite of the progress in cardiology within recent years the treatment of heart disease is as unsatisfactory now as it was 20 or 30 years ago. What are the indications for the administration of any specific drug in the various forms of heart disease? How long should the use of that drug be continued? Which are the factors determining the exact dose of a drug to be prescribed? It is impossible to answer adequately these questions in the absence of a comprehensive principle from cardiotherapy on which we could rely as a guide. In this paper an attempt is made to determine whether by an application of exact methods to cardiotherapy it might not be possible to discover some principle which might act as basis for a more rational treatment of heart disease. The leading idea is to develop a standard by which the degree of abnormality in the cardiac mechanism can be gauged, and I shall attempt to prove that the intra-cardiac pressure supplies such a standard, not only for diagnostic but also for therapeutic purposes; for in determining the effect of a given drug on the intra-cardiac pressure, we shall at the same time be enabled to draw conclusions as regards its therapeutic effects on the cardiac disturbance.

It is clear that if an abnormal mechanism is to be corrected, it is desirable that the exact nature of its divergence from the normal should be known; it is equally clear that if a drug is to be prescribed for the purpose of remedying a defective mechanism it is necessary to ascertain the exact effects which such a drug exercises on that mechanism.

Estimation of Intra-cardiac Pressure.

First of all we shall have to find out whether the intra-cardiac pressure can with some degree of certainty be determined. I propose the estimation of the intra-cardiac pressure by ascertaining the duration of the diastole in relation to the systole.

The electrocardiograph offers an easy and accurate method of measuring the length of systole and diastole. It is assumed that a relatively long diastole in relation to a short systole signifies a high intra-cardiac pressure, since in a long diastole a large quantity of blood is permitted to be collected in the ventricles, which has to be expelled in a relatively short systole and therefore under higher pressure. It is true that the length of the diastole does not always stand in a definite relation to the quantity of blood which flows into the ventricles. Under increased venous pressure a relatively large quantity of blood will reach the ventricles, even if the diastole is of short duration. On the other hand, under the influence of digitalis the pressure in the jugular veins is so low that blood flows into the auricle at a slower rate. However, it is only in extreme cases where this factor is so considerable as to influence materially the relation between the length of the diastole and the quantity of blood which the ventricle receives. Moreover, there are two well-known facts which demonstrate conclusively that a long diastole strains the heart muscle to a greater extent than a short one. It is a general law in physics that the pressure in a fluid acts in all directions; therefore the tension caused by any given fluid on the walls of a closed vessel will increase with the diameter of the vessel. The total tension on the muscular walls of the heart will be greater the longer the diastole lasts. This is one fact. The other fact is concerned with the anatomical construction of the heart. With increased distension the walls of the heart become thinner, and the number of muscle fibres in a given area fewer, so that the longer the diastole the more strongly will each fibre have to contract in order to produce a given tension in the enclosed blood.[1] I think, therefore, we may safely assume, everything being equal, that the strain which the heart muscle has to bear during its systole will be proportionate to the length of the diastole. It is possible to some extent to supplement the data derived from the duration of the diastole in regard to the intra-cardiac pressure by measuring the pulse pressure.

The Two Types of Heart Failure.

I shall proceed now to ascertain the changes which heart failure produces on the intra-cardiac pressure, and will deal later on with the effects of some drugs on the tension of the heart chambers. We shall be then in a position to judge as to whether the knowledge gained from both could be usefully applied.

Two factors are concerned in the production of heart failure: the condition of the heart muscle and the intra-cardiac pressure. A moderate intra-cardiac pressure acting on a damaged heart might suffice to produce heart failure. An abnormally high intra-cardiac pressure acting on a healthy muscle should, theoretically at any rate, also be able to induce heart failure. To remedy such an abnormal condition either of two courses is open to us: we may decrease the intra-cardiac pressure or we may strengthen the heart muscle.

All cases of heart failure do not present a common symptomatology. Heart failure must be divided into two distinct types, with a characteristic group of symptoms for each. One type is commonly met with in young people with a moderate degree of hypertrophy of the left ventricle, the arterial blood pressure, which is never unduly high with these patients, becoming lowered along with failing compensation; the heart is dilated and the pulse frequency high. Œdema is often present in this type of heart failure and easily amenable to treatment. Præcordial pain might be present, but of a type different from that of the pang of angina. Sudden death is an extremely rare occurrence in these types of deficient heart action. The most striking feature of this type of heart failure is the normal condition of the arteries and the peripheral circulatory apparatus in general.

The other type of heart failure is common in patients which show either pronounced hypertrophy of the left ventricle or sclerosis of the heart muscle with a high arterial blood pressure. Deficient compensation manifests itself often by an angina-like pain at the cardiac region. The arterial blood pressure does not fall even with the advent of general œdema. I have observed in some cases even an actual increase of blood pressure after the appearance of œdema. The latter is less common in these cases, but when present stubbornly resisting treatment. The pulse does not show any acceleration. Sudden death is of common occurrence in this type of heart failure. But the most striking feature in this form of failing heart is the sclerosis of the arteries and the general pathological condition of the peripheral circulatory apparatus.

Changes in Intra-cardiac Pressure in Heart Failure with Normal Arteries.

If we now examine the different phases of the heart beat in the first type of heart failure we find the most characteristic feature of the abnormal mechanism is a considerable shortening of the diastole. The length of diastole may be equal to or even less than the length of the systole. As the pulse becomes quicker the diastole becomes shorter and shorter, whilst the length of the systole remains nearly the same as in the normal condition.

---

[1] Starling: Physiology.

However, as soon as a certain rate of acceleration is attained, the systole becomes suddenly shortened to a considerable degree, a kind of new rhythm sets in, with a somewhat altered relationship in the length of diastole to the systole, the duration of the diastole in relation to systole becoming somewhat longer, as was the case immediately before the sudden shortening of the systole. The intra-cardiac pressure in such cases must be very low, since, as we have already seen, the amount of blood contained in the ventricle at the beginning of the systole must bear some relation to the time available for the inflow of the blood from the veins into the heart. The low intra-cardiac pressure in this type of heart failure is significant. The symptomatology in this type of heart failure is in the nature of an adaptation, the rapid pulse acting as a safety-valve to obviate more serious consequences. As the heart muscle is unable to withstand a normal intra-cardiac pressure, the pressure falls so low that even a weak muscle is able to cope with the slight strain thrown on the heart during the systole. It is quite true the heart has to make up for the smallness of the output at each systole by an increased number of contractions during a given time. Sometimes, of course, the total output in rapid heart action does not compensate sufficiently for the smallness of the output of a single contraction, with the result that engorgement of veins and œdema make their appearance. These must be regarded as secondary effects of an otherwise beneficial process. We understand now why sudden death is uncommon in these cases. The more one surveys the symptomatology of a series of cases showing this type of heart failure, the more one observes the important part which this adaptation plays in heart disease. The one supreme aim of nature in these cases is apparently to prevent *at all costs the undue straining* of the diseased heart muscle, which would lead to fatal results.

There are a few additional facts. Cases with only a moderate degree of compensation react on work, as we all know, by a greater increase in the pulse-rate than the normal heart does in the same circumstances. The increased demand on the heart is met in the normal heart mainly by an increase in the force of the heart beat, whilst in the diseased heart the pulse-rate increases instead. The increase of force in the single beat would, of course, mean an increase in the cardiac pressure, which is to be avoided. On the other hand, cases which show the second type of heart failure do not react on work with the same rate of acceleration of the pulse.

The same adaptation is observable in cases where there is a permanently rapid heart action due to myocarditis. The arterial systolic pressure is quite normal in these cases, since the total output of the heart in a given time is normal. The diastole is extremely short in these cases, often even shorter than the systole; the pulse pressure is very low. Finally, we find the same adaptation in fevers, where the myocardium is not in a fit condition to resist the high intra-cardiac pressure. In these cases there is often a loudness of the first sound, which signifies, as it always does, an incompletely filled ventricle, and thus supplies additional evidence of the low state of pressure existing in the chambers of the heart.

In all these cases the heart is the primary organ to be affected; the condition of the arteries and the rest of the circulatory apparatus is either normal or only slightly affected. The protective adaptation develops in the interest of the central organ alone. The demands made on the heart by the various organs of the body are not complied with if these demands entail too great a strain on the heart muscle. Then œdema appears and the peripheral circulation is disturbed, the systolic pressure falls, and the work of the heart is actually less than normal. The heart is actually under less strain in this condition than normally. The adaptation in these cases is all in favour of the heart muscle. The feature which concerns us here mostly is the fact that the intra-cardiac pressure is very low in this type of heart failure. The object of treatment here cannot, therefore, be the reduction of the intra-cardiac pressure, but the strengthening of the heart muscle. Any drug which acts as a tonic of the heart, even if it raises the intra-cardiac pressure, would answer our purpose.

Changes in Intra-cardiac Pressure in Heart Failure Associated with Arterio-sclerosis.

Let us observe now the mechanism of the second type of heart failure. The pulse-rate is not increased. The length of the systole in relation to the diastole remains the same as before the onset of heart failure, the intra-cardiac pressure remaining very high. The two factors which are immediately responsible for the heart failure have not altered. This is the reason why sudden death is so common in this type of heart disease.

The clinical features of this type of heart are totally different from the foregoing one. The mechanism here, too, is an adaptation, but an adaptation of a different order. In cases which show the first type of heart failure the adaptation is entirely in the interest of the central organ. In the cases we are dealing with at the moment the adaptation is entirely in the interest of the peripheral circulation, which entails, however, effects reacting disadvantageously on the central organ. The chief characteristic of this type of heart disease is a disturbance in the peripheral circulation, sclerosis of the blood-vessels, and an increased arterial tension.

From the beginning the trouble which the circulatory apparatus had to contend with lay on the peripheral side of the circulation, and the adaptation accordingly developed in the interest of the latter. The high arterial pressure and the increase in force of the single beat are obviously beneficial arrangements to overcome an increased resistance in the peripheral circulation. They who depreciate the value of a high peripheral pressure should reflect for a moment on the causes which give rise to cardiac asthma. This is due to a fall of arterial pressure. The comparatively low pressure does not constitute a strong enough driving force to overcome the resistance in the sclerotic coronary arteries, which results in temporary weakness of the heart muscle. This is the reason why the attack takes place in the greatest number of cases at a time when the patient is at complete rest and the arterial pressure at its lowest.

But to return to our main theme. We have seen that the pulse is slow, the arterial pressure high, becoming often higher with the appearance of general œdema. But perhaps the most striking feature of a typical case of this kind is the entire absence of jugular engorgement even when the general œdema is very much marked.

In a case I have in mind general œdema was present for many weeks, and jugular engorgement was absent to the very last moment of life. Surely the absence of jugular engorgement could not be explained in a case so serious by the assumption that the right ventricle remained normal till the last. However, if we consider the duration of the diastole in relation to the systole we must really not expect any engorgement of the jugular vein, since a long diastole provides plenty of time and plenty of space for veins to empty themselves into the auricles. There can be no question of back pressure in their case, since the increase in the arterial pressure shows that the heart action remained at least as powerful as ever. Now the generally accepted theory of the origin of œdema is backward pressure from the auricles, which causes engorgement and increased pressure in the veins, a theory which is quite compatible with all the clinical symptoms of the first type of heart failure. But how could the backward theory be made to account for the œdema of a case where the jugular vein is not engorged at all?

Still another feature came under my observation in connexion with this type of heart. It was a case of high systolic pressure, arterial sclerosis, nephritis, and aortic regurgitation. There was general œdema, but the systolic pressure remained high. I applied pressure on one of the veins on the dorsum of the hand by means of the Hooker apparatus. As soon as the pressure on the vein reached a certain degree the distal end of the vein began to show marked pulsations; the latter have been powerful enough to lift the water in the manometer about a fourth of an inch. This will give us some indication of the height of tension existing in the part of the circulation which lies between the arteries and this vein. All these facts make it probable that the course and origin of œdema is different in this type of heart disease from the type mentioned before. The œdema in these cases could not have originated from back pressure, but is more likely to have been caused by forward pressure—that means, of course, if undue pressure in any part of the circulation is the cause of œdema at all.

We have seen before that the appearance of œdema in cases which show the first type of heart failure actually lessens the total output of the heart and the strain of the heart is correspondingly diminished. Here, however, the œdema does not lessen the output of the heart. The adaptation in the interest of the peripheral circulation continues, and since the peripheral resistance has increased, the arterial pressure correspondingly increases in height. Increase in arterial pressure not followed by increase of the pulse-rate means increase in force of the single beat. Increase in force of a single beat means a greater intra-cardiac pressure.

What we are concerned with here mostly is the fact that the increase in tension in the rigid and sclerotic chamber of heart continues, even when symptoms of heart failure manifest themselves. The indication for treatment is obviously here to administer such drugs as should lower the intra-cardiac pressure and at the same time interfere as little as possible with the peripheral pressure.

The Effect on Intra-cardiac Pressure of Certain Drugs.

I shall say a few words in regard to those drugs which are in frequent use in the treatment of heart disease, and indicate the effect they exercise on the intra-cardiac pressure.

Digitalis in larger doses delays conductivity, produces double rhythm, an inverted T, and an electro-cardiac depression at the height of the systole. The appearance of one of these signs might be an indication to discontinue the drug in almost all forms of heart disease. Digitalis administered in small doses increases slightly the systole, whilst considerably prolonging the diastole, at the same time the intra-cardiac pressure is not much altered. Digitalis administered in medium doses will actually decrease somewhat the length of the systole and prolong slightly the diastole, the pulse frequency remaining unaltered. Digitalis in large doses decreases both the systole and diastole, the latter to a lesser extent. Medium doses of digitalis increase the intra-cardiac pressure, whilst large doses lower it considerably.[2]

Strychnine.—After enjoying great popularity this drug has been in disrepute within recent years. I am not in possession of any records taken from the patient immediately after the administration of strychnine. The greatest part of my material on which the subsequent conclusions rest is derived from the out-patient departments of the Northern Hospital. A few records are from my private electro-cardiograph practice.

The following table is a characteristic record of the effect of strychnine on the pulse frequency.

	Lengths of Pulse in Seconds.
Before the administration of strychnine...	·74, ·68, ·72, ·76, ·68, ·68, ·68, ·68, ·68, ·68, ·68, ·68.
A week after the continuous administration of ♏ v. strychnine thrice daily	·72, ·72, ·76, ·72, ·74, ·74, ·72, ·76, ·68.
A fortnight after the continuous administration of strychnine...	·80, ·82, ·84, ·83, ·83.
A fortnight after the discontinuance of strychnine	·76, ·76, ·76, ·76, ·76, ·76.

Strychnine also seems to have a favourable influence on the irregular heart action. Before the administration of strychnine 40 beats showed 19 premature beats; a week after the administration of strychnine about the same number of beats showed 8 extrasystoles; the continuation of strychnine to another week had the effect of reducing the number of extrasystoles to 3. As the same phenomenon has been often observed it cannot be an accidental occurrence. Strychnine certainly does not lower the pulse frequency in every instance. But my record demonstrates that strychnine is capable of influencing the pulse frequency. It is important to note that strychnine never disturbs the relation of the different phases of the heart beat to each other, as is the case with digitalis.

Caffeine.—The chief characteristic of caffeine cardio-electrographically is the effect it has on the shape of T, which becomes markedly pronounced under its influence. I do not know the meaning of this phenomenon. (An inverted T in some leads is certainly a pathological sign, so also is the entire absence of T.) A well-developed T is found in young people. In the majority of my cases caffeine affected the relative size of the diastole to the systole, the latter increasing to a slight extent in length. Caffeine accelerates the pulse frequency. Caffeine certainly does not decrease the arterial pressure. The same drug can frequently be seen to neutralise some of the electro-cardiac peculiarities produced by digitalis. It will accelerate conductivity, remove digitalis depression, and prevent the inversion of T.

Camphor shows similar effects in regard to T as caffeine.

In regard to *atropine* I have not much to say. In accelerating the pulse frequency it also effects a shortening of the diastole and a considerable fall in the intracardiac pressure.

Conclusions.

Let us now see what use we can make of the principles enunciated in this paper. It is clear digitalis is indicated in cases which show the first type of heart failure. The tonic virtues of digitalis will act on the heart muscle before the intra-cardiac pressure-raising properties of digitalis can have an effect on the heart. The exact doses of digitalis can be regulated by taking as guide the state of the intra-cardiac pressure, particulars of which I have given elsewhere. If we come to cases showing the second type of heart failure it is obvious digitalis in such cases is not indicated. Any drug which might increase the intra-cardiac pressure would only aggravate matters. The most pressing symptom calling for immediate interference is the high intra-cardiac pressure. The best thing is to imitate nature's cure of the first type of heart failure. The ideal treatment in such cases would be one which would lower the intra-cardiac pressure and at the same time leave the arterial pressure unaltered. The prolonged use of nitrites is contra-indicated in such cases because they lower the arterial pressure so much. Caffeine seems to have all the properties we require for treatment of such cases, since it lowers the intra-cardiac pressure and does not decrease arterial tension. Clinical evidence, too, seems to confirm the usefulness of this drug in such cases. Unfortunately, many patients cannot take caffeine for any length of time on account of the nervous excitability which this drug induces. We have to fall back on atropin. This drug, by increasing the pulse frequency, diminishes considerably the intra-cardiac pressure. It is a good plan to treat the patient alternately with caffeine and atropine. As soon as the pulse-rate is considerably increased the intra-cardiac pressure falls proportionately. Small doses of digitalis are useful now, the drug to be continued till there is evidence of a consider-

---

[2] Harris: Quarterly Journal of Medicine, vol. xiii., No. 49, October, 1919.

able rise in intra-cardiac pressure. Digitalis benefits the heart muscle, even in rapid heart action. Atropin lowers the arterial blood pressure somewhat, but not to such extent as the nitrites.

The treatment of œdema by digitalis is contra-indicated in these cases, particularly as the dose required for this purpose would be a large one. Digitalis, of course, might lessen the œdema in such cases. But the cardiac pain, the great discomfort of the patient, and the danger of sudden death would increase under digitalis.

Puncturing of the lower extremities are useful and quite safe if the rules of asepsis are observed. I found adrenalin a most useful drug for removal of œdema in such cases. Adrenalin probably acts as a diuretic, and does not affect the intra-cardiac pressure. Where digitalis is indicated graphic methods will be able to guide us in respect to the exact doses of the drug it is safe to administer. Caffeine acts in many respects as an antidote to digitalis, and one is able to neutralise the objectionable features of the latter as manifested by electrocardiographic signs, by countering digitalis with caffeine.

Such is a crude outline of the value of exact methods in cardiotherapy, which I hope is capable of development.

TWO CASES OF
INTRAMEDULLARY TUMOUR OF THE SPINAL CORD,
WITH OPERATION.

By ANTHONY FEILING, M.D. CANTAB., M.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE; ASSISTANT PHYSICIAN TO THE METROPOLITAN HOSPITAL; CASUALTY PHYSICIAN TO ST. BARTHOLOMEW'S HOSPITAL.

TUMOURS of the spinal cord or its membranes are sufficiently rare to arouse interest at any time, and more especially when they are of the intramedullary type—that is, arising in the substance of the spinal cord itself. At the present moment, when the wounds of war have added to our experience of neurological surgery, it seems the more appropriate to record these two cases of intramedullary tumour. The cases themselves, both in their clinical course and from the nature of the tumours, present many points of great interest to the neurologist. Frazier's recent text-book[1] affords the most complete bibliography on the subject of spinal tumours yet available. Out of the 330 cases of spinal tumour in which an operation was performed only 36 examples of intramedullary tumour were found (10·9 per cent.). In Schlesinger's report of 35,000 autopsies at Vienna 135 cases of spinal tumour were found, of which 20 (14·8 per cent.) were of the intramedullary type. Since the number of spinal tumours formed only 2·06 per cent. of the total number of tumours of all kinds it will readily be seen that the condition is a rare one. Intramedullary tumours more commonly take the form of an infiltrating growth of the cord, though the encapsuled forms have been described. Out of the 36 cases collected by Frazier where operation had been performed 9 were examples of glioma, and this is stated to be the most common form of growth. The first case here described is a case of psammoma of the cord, and is, I believe, the first of such to be recorded.

CASE 1.—J. W. P., male, aged 18, was admitted to the Hospital for Epilepsy and Paralysis, Maida Vale, on Feb. 2nd, 1919, under the care of the late Dr. Fearnsides, after whose death he passed into my charge. The history of the case was as follows. About eight years before he had begun to lose the use of his legs; the onset of this weakness was very gradual and had not been accompanied by any pain at all. From July, 1912, to July, 1913, he had been a patient in the wards of the National Hospital for the Paralysed and Epileptic, Queen-square. I was allowed to see the notes of the case, and found that diagnosis of spinal caries with compression of the cord had been made. From that time until he came under observation at the Hospital for Epilepsy and Paralysis, Maida Vale, the progress was steadily downhill, until he gradually became unable to walk at all. Severe flexor and adductor spasms of the legs became a troublesome symptom, but no pain beyond a somewhat vague and ill-localised discomfort in the mid-dorsal region had been felt. He had occasionally experienced a difficulty in passing water, but there had never been involuntary escape of urine. He stated, however, that he did not feel his urine passing. There had never been any loss of control over the rectum. There was nothing in the previous history worthy of mention. In July, 1919, when I first saw him, the condition was as follows. He was quite unable to walk without assistance. He complained of a dull aching pain referred to the midscapular region, and also of cramps in his legs. These latter were really severe flexor and adductor spasms of the legs and thighs, which not only caused great discomfort but actually prevented sleep, and, further, were a not unimportant contributory cause of his inability to walk. No physical signs of disease could be found in the eyes, cranial nerves or upper extremities. Examination of the thoracic and abdominal viscera was negative. Both upper and lower segments of the recti abdominis were paralysed, and the abdominal reflexes were absent. The legs were in a condition of extreme spastic paraplegia, and when he was lying quietly in bed were usually extended. Any attempts at voluntary movement, however, or any handling of the legs produced violent flexor and adductor spasms. Both knee-jerks and both ankle-jerks were much exaggerated, and ankle clonus was obtained in both legs. The plantar reflexes were extensor, and the extension of the toes was accompanied by a general flexion movement of the whole limb. There was a gross loss of sensation present, but this was not constant and was variable in extent. No absolute loss of light touch sensation could be demonstrated, nor any complete loss to pinprick, but there was a blunting to pinprick as high as the costal margin in the anterior axillary line on each side.

Appreciation of heat and cold was defective as high as the nipple line; but here the limits were even more inconstant and vague. On the right side there was a narrow band of hyperæsthesia at the level of the seventh dorsal segment of the cord. The sense of muscle pain was preserved in the legs and the vibration sense only slightly diminished. The spasticity and spasm prevented any useful testing of the sensations of the position and passive movements of the joints. Examination of the spinal column displayed two curvatures—a scoliosis in the dorsi-lumbar region and a kyphosis in the dorsal region. No definite local, tenderness or rigidity could be found. From an X ray examination Dr. Gilbert Scott reported a slight curvature of the fourth, fifth, and sixth dorsal vertebræ and some loss of definition of these bodies. At this time there was no interference with the control of the bladder or rectum, except that the patient could not feel his urine passing. The Wassermann reaction in the blood was negative. The cerebro-spinal fluid was clear, reduced Fehling's solution normally, gave a negative test for globulin, contained no cells and no organisms, but gave a feeble but definitely positive Wassermann reaction. Diagnosis was naturally in doubt. I did not consider that the case was one of spinal caries, but thought rather that the cord was compressed either by some slowly-growing tumour or possibly by some localised inflammatory condition, with

---

[1] Frazier: The Surgery of the Spine and Spinal Cord (with complete bibliography).

perhaps an encysted collection of cerebro-spinal fluid. The absence of pain was a point against the diagnosis of extramedullary tumour, and the possibility of an intramedullary tumour was suggested but not maintained. No very material alteration in the patient's condition took place during the next six weeks, except a slight increase in the extent of the sensory loss. Thus, on August 18th the loss of sensation to pinprick extended to just below the nipples on the right side (dorsal 5) and on the left side to about two segments lower down. He now experienced occasional difficulty in passing urine.

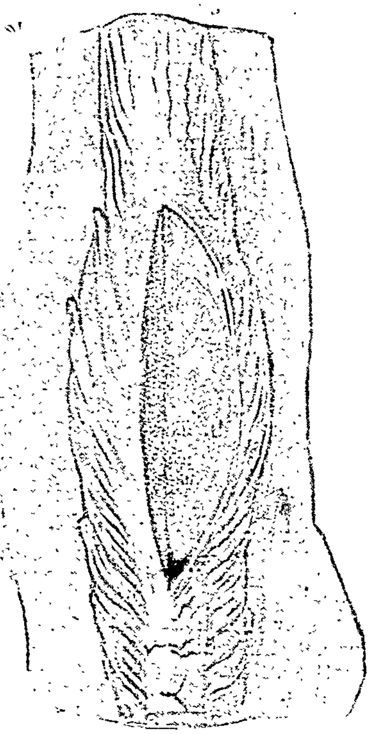

FIG. 1.—Intramedullary tumour (psammoma) of the spinal cord found post mortem in Case 1.

Operation was suggested and agreed to by the patient and his parents. In advising this I was fully conscious that an exploratory laminectomy was really what was being proposed, and I recommended it as the only course which might lead to cure or improvement. I therefore asked my colleague, Mr. Blundell Bankart, to operate and explore the cord at the level of the fifth dorsal segment. On August 23rd he performed the operation of laminectomy, removing the spines and laminæ on the first, second, third, and fourth dorsal vertebræ. To our great disappointment no tumour or other abnormality was found, and a probe appeared to pass readily up and down the theca in all directions. The cord itself was not incised. The wound was therefore closed. Next day there were complete paraplegia and retention of urine. On the 28th signs of an acute cystitis appeared. By Sept. 1st there were fever and pyuria. The legs became quite flaccid, and all the reflexes were lost with the exception of a feeble extensor response in the great toes. He died on Sep. 12th. A post-mortem examination was made soon after death. Death was due to infection of the urinary tract with consequent toxæmia. Both kidneys showed a well-marked condition of pyelonephritis with the formation of small abscesses; the ureters contained pus and the mucous membrane of the bladder was swollen, hæmorrhagic, and in several places sloughing. The operation wound was clean and well healed. The spinal cord was removed intact and hardened for several days before being examined. There was no sign of spinal meningitis. Further examination then revealed the presence of a fusiform enlargement of the cord, occupying as far as could be determined the first three dorsal segments; it was quite firm and harder than the ordinary substance of the cord itself. The incision in the dura mater made at operation was just ½ inch below the lower extremity of the tumour. A good idea of the extent and appearance of the tumour may be gained by reference to the accompanying sketch. (Fig. 1.) The tumour itself lies entirely within the cord, and is not in any way attached to the meninges. It is oval in shape, about 1½ inches in length, strictly-circumscribed, and of a peculiar greenish colour rather like that of chloroma. Dr. T. H. G. Shore examined it microscopically, and reported as follows: "The tumour consists of spindle cells of short type, together with some rounded cells; in places the spindle cells can be seen arranged in whorls, but most of these groups have undergone degeneration to form the spherical gritty particles so apparent to the knife on macroscopic section. These gritty particles form the striking feature of the section. The whole structure is typical of a psammoma."

CASE 2.—H. H., male, aged 14, was admitted to the Hospital for Epilepsy and Paralysis, Maida Vale, on Sept. 26th, 1919, complaining of weakness of the legs. The history was as follows: Until 6 years old he seemed perfectly well, after which he appeared delicate and did not gain weight. For about the last four years he had been observed by his parents to be clumsy on his feet, but this disability had not prevented him from playing games, &c. About a year or 18 months previous to admission to hospital a slight curvature of the spine was noticed. About six weeks before admission a marked weakness of the legs appeared, which rapidly grew worse, so that he became unable to walk at all. He had had no pain. There had been no retention of urine and the control over the rectum was not affected. Beyond an attack of whooping-cough as a child he had had no previous illnesses of any importance and there was no family history of any nervous disease or of tuberculosis.

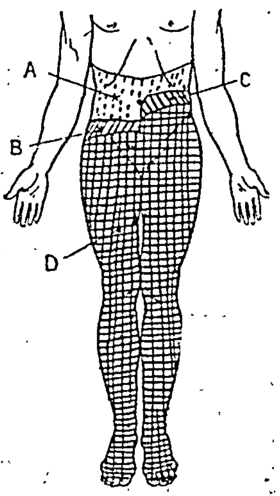

FIG. 2.—Chart showing loss of sensation in Case 2. A, Area of hyperæsthesia. B, Loss of touch sensation only. C, Loss of pinprick sensation. D, Loss of all forms of sensation.

On examination on Sept. 30th the condition was as follows: Examination of the eyes, cranial nerves, and upper limbs showed no abnormality. There were no physical signs of disease in the heart or lungs except a few scattered râles in the lower lobe of the left lung. The spine showed a slight kyphosis in the mid-dorsal region and a slight scoliosis, with convexity to the right. There was no tenderness on percussion of the spines and no rigidity of the spinal column. No signs of disease were found in the abdomen. Both upper and lower segments of the recti abdominis were acting, but the abdominal reflexes were not obtained. The legs showed a condition of flaccid paraplegia, and were extended flat in the bed. There was no obvious atrophy. A certain amount of voluntary power was still present. In the left leg tolerably good flexion at the hip-joint was still possible, extension was less well performed, and adduction and abduction were very feeble. Flexion and extension at the left knee-joint were possible but weak; there was no voluntary movement at the ankle-joint or at the toe-joints. In the right leg feeble movements of flexion and extension of the hip-joint alone were present. Both knee-jerks and both ankle-jerks were lost. On stimulation of the sole of the foot no definite movements of the big toes were obtained, but a general flexion reflex of the whole limb could be produced on each side by any nocuous stimulus; the receptive field of this reflex extended from the hips downwards and really embraced the whole limb. No reflex was obtained in the contralateral limb. There was a great loss of sensation present. This is best appreciated by a reference to the accompanying chart. (Fig. 2.) Briefly all forms of sensation were lost below the hips, while sensation of light touch and temperature were lost as high as the umbilicus; on the right side there was a narrow band of hyperæsthesia at the level of the umbilicus; on the left side the sensory loss extended about one segment higher than on the right. Micturition was normal; the urine showed no abnormality;

X ray examination of the spine revealed no abnormality. The Wassermann reaction in the blood was negative. Lumbar puncture revealed a very interesting alteration in the cerebro-spinal fluid. Only a very small amount, about 1 c.cm., could be obtained; this was clear and of a beautiful golden-brown colour, with a peculiar iridescence. After centrifugalisation only five lymphocytes and one polymorphonuclear cell were seen. No cholesterin crystals were seen. The Wassermann reaction was negative. The small quantity precluded further chemical tests, but the fluid did not show the heavy spontaneous coagulum described as part of Froin's syndrome.

The progress was steadily for the worse. By Oct. 13th complete retention was present and catheterisation was necessary; no automatic action of the bladder was present, and dribbling took place. By the 27th the urine contained a trace of pus. On the 28th the following note was made. Eyes, cranial nerves, and upper extremities all normal. Complete paralysis of the right lower limb; in the left lower limb the following movements are possible: at the hip-joint slight flexion, slight adduction and abduction and slight rotation; at the knee-joint slight flexion only; at the ankle-joint slight flexion and extension. Very feeble power of movement of the left toes. The upper segments of the recti abdominis were acting. Mild flexor spasms of both lower limbs present. Some general wasting of the whole body, but more especially of the legs.

Reflexes.—Arm-jerks present and equal. Abdominals. The right epigastric reflex only obtained, and that sluggishly. Bulbocavernosus and anal reflexes present. Both knee-jerks and both ankle-jerks lost. Typical flexion reflex obtained by stimulation of the sole of the foot. No response obtained in the contralateral limb.

Sensation.—No pain in the lower limbs; a dull pain in the back at the level of the third lumbar spine. No vasomotor or trophic changes of any importance to record. Retention of urine present, with overflow only when the bladder is allowed to become distended. No appreciable change in the level of the sensory loss, except that there is now a wider area of hyperæsthesia above the level of the loss of sensation, extending to just above the costal margin on each side.

The diagnosis naturally presented considerable difficulty, but after consultation with my colleagues I finally decided that the most probable cause was a tumour of the cord, very likely of the intramedullary type, and operation was decided upon. The level of the tumour was judged to be the ninth dorsal segment of the cord, but with the lesson of Case 1 before us and bearing in mind the general tendency to place the tumour too low a wide exposure, going well above the level of sensory loss, was decided on. Accordingly, on Oct. 30th Mr. Blundell Bankart performed the operation of laminectomy and removed the spines and arches of the fourth, fifth, sixth, seventh, and eighth dorsal vertebræ. The bone and meninges were normal. The cord was slightly rotated and exhibited a fusiform swelling about 1½ inches in length, at the level of the sixth, seventh, and eighth dorsal spines. In colour the swelling was dark red and proved to be an intramedullary tumour, covered by a thin shell of normal cord substance. An incision about an inch in length was made in the long axis of the tumour and down the postero-median septum of the cord. Some old and recent blood escaped and a small amount of rather sticky gelatinous material, some of which was carefully preserved for microscopic section. The incision into the tumour was left open, as well as the lower part of the incision into the dura mater, with the idea that it might act as a decompression of the cord, and in the hopes that the tumour might possibly extrude itself, as occurred in a case reported by Elsberg. The wound in the muscles and skin was closed without drainage. The operation was well borne. Complete paraplegia, however, naturally ensued, and the patient complained of a good deal of pain in the back. The urine fortunately remained free from infection in spite of the continual catheterisation which was necessary.

On Nov. 11th, 12 days after the operation, the condition was as follows: Abdominal reflexes absent; neither upper nor lower segments of the recti abdominis acting. Complete paralysis of the right lower limb; some return of power in the left lower limb, consisting of feeble flexion of the hip and slight up-and-down movements of the toes. Both knee-jerks and both ankle-jerks absent. Stimulation of the soles of the feet gave a feeble and easily exhausted extensor response, with a well-marked flexion reflex. No appreciable alteration in the sensory loss appeared. There was retention of the urine, with overflow incontinence, if the bladder was not emptied by catheter. Loss of control of the rectum was present after an aperient. Slow but steady improvement took place, and on Dec. 1st it was noted that the voluntary power in the left leg had increased, and that a certain amount of automatic action of the bladder was established, the bladder evacuating itself when it contained about 3½ oz. of urine. No urinary infection was present. A microscopic examination of the piece of material removed from the spinal cord at the operation was made by Dr. R. G. Canti, who reported as follows: "Section shows the structure of a glioma. The growth is necrotic and is supplied with large blood spaces. There is no normal tissue present." At the time of writing the patient is still under observation in hospital. The condition is about the same as when he was first admitted—that is, he seems to have recovered from the effect of shock to the spinal cord, while, as might be expected from the nature of the tumour found, no real improvement has taken place in the paralysis.

Remarks.

The first point of interest in these two cases is the striking difference in the clinical course exhibited by them. This difference may, of course, be explained by the histological characters of the tumours. The first, that of the psammoma, is characterised by extreme chronicity, eight years' duration, and but for the unfortunate result of operative interference and urinary infection life might have been prolonged for a considerable time, albeit with complete paraplegia. The second, that of the glioma, is marked by a rapid onset of symptoms, practically complete paraplegia being attained in six weeks, though premonitory symptoms had been present for some time before. The absence of pain, or at any rate of any severe pain, is a second striking fact and forms a valuable point of differential diagnosis from the more common extramedullary tumours. The inconstancy of the sensory loss in Case 1 was a noticeable feature, and is perhaps a point of some value, since extramedullary tumours usually lead by compression of the cord to a definite segmental loss, though this may often be of the Brown-Séquard type. In neither of the cases was the typical picture of a complete transverse lesion of the cord produced. Even in Case 2, where the mass reflex was typically present, some motor power still remained and distinct differences between the relative power of certain muscle groups could be easily demonstrated. It is interesting to note that a curvature of the spine was present in both cases. This may, of course, be a mere coincidence, but in view of the well-known association of spinal curvatures with syringomyelia, which is essentially an intramedullary gliosis, it may possess some diagnostic value. The lamentable termination of Case 1 emphasises the greatest danger to which these patients are subject—infection of the urinary tract—and illustrates the importance of operating early where operation is indicated. For sepsis in the urinary tract greatly diminishes the chances of successful surgical interference. Laminectomy in experienced hands is not an operation which need produce much shock, and the actual risks are being rapidly reduced to very small proportions by increasing skill and knowledge. Hence a somewhat bolder policy may be expected in the future in dealing with the possibilities of operation in doubtful cases. Localisation on the level of the tumour of course calls for the greatest care, and it is well to bear in mind the almost universal experience that there is a tendency to place the tumour too low in cases where any doubt exists as to the exact level of the growth. This tendency was well exemplified in Case 1. Cases of intramedullary tumour of the cord where removal of the growth is possible are likely to be very few, though attempts at doing so have been recorded by Potel and Veadeau and by Elsberg; the latter advocates an incision being made into the cord in order that the tumour may extrude itself and a decompression of the cord be effected. Robinson has recorded a case of intramedullary tumour of the cord which survived for two years after operation. Whether such operations are justifiable is a fair question. And it must be confessed in the two cases here recorded that the results are not very encouraging. But it is important to remember that all experienced observers are agreed as to the impossibility of making an absolute diagnosis in all cases between an extra- and an intra-medullary tumour. And the hopeless outlook for these cases, if unrelieved by operation, renders operation a perfectly just and reasonable course, if only in the hope that the tumour may prove to be of the extramedullary type and of a nature capable of removal. In skilled hands the actual operative risks should be small. Such operations, however, should only be undertaken by those who have had special experience of this branch of surgery, and, it is hardly necessary to add, not before the possibilities of diagnostic error have as far as possible been excluded.

In conclusion, I wish to express my thanks to my colleagues at the Hospital for Epilepsy and Paralysis, Maida Vale, who saw the patients in consultation with me, and especially to Mr. Blundell Bankart, who operated in both cases. To the resident medical officer, Dr. F. J. Hampton, I am much indebted, particularly in Case 2, where the results, so far encouraging, have been in no small measure due to his constant care and attention.

NOVOCAINE ANÆSTHESIA.

SOME DISADVANTAGES FROM A SURGICAL STANDPOINT.

By G. H. C. ST. GEORGE GRIFFITHS,
M.R.C.S., L.R.C.P. LOND.,
LATE SURGEON-LIEUTENANT, R.N.; ANÆSTHETIST AND SURGEON-LIEUTENANT "OPERATOR-IN-CHIEF" TO ROYAL NAVAL HOSPITAL, HASLAR.

IN writing these few personal observations I must apologise to the experts if any points mentioned seem to them elementary. No attempt has been made to describe details about injection or sterilisation of the solution used, as these and other equally important matters can be found in the larger text-books on the subject. In the following criticisms it might be thought that I am unfavourable to operating under local anæsthesia. The object of the criticisms is only to warn novices against the many avoidable pitfalls. I believe that some day, when "nerve blocking" is better understood, that any operation will be carried out under novocaine in order to avoid the always present risks of general anæsthesia. No one who witnessed the scores of resections for empyema at Haslar Hospital during the late scourge could doubt the brilliant future of local anæsthesia.

Preliminary Precautions: Strength of Injection.

An exceedingly important detail from the surgeon's standpoint is the careful preparation of the novocaine solution previous to injection. As this is frequently dispensed by men unfamiliar with asepsis, the risk of possible sepsis in the wound after operation must be considered. A clean but "septic" glass stopper or bottle may result in many heart-burnings.

Another difficult and delicate subject that is apt to arise is the anæsthetist's surgical cleanliness. Anæsthetists can grow careless over their asepsis in administering subcutaneous injections. Granted that these two extremely important points are attended to, the mode of injection may now be briefly described.

The use of novocaine solution in 2 per cent. and 5 per cent. strengths is recommended by various authorities. In experiments at Haslar Hospital perfect anæsthesia was obtained with 0·5 per cent. solution of novocaine, and this strength was adopted as routine for all operations performed under local anæsthesia. Each ounce of the solution had 5–10 minims of adrenalin (1–1000) added to act as a hæmostatic. These local measures were supplemented by a hypodermic injection of scopolamine gr. 1/150 and omnopon gr. 1/6} about 15 minutes previous to making the incision. This was sufficient to make the patient dazed or extremely sleepy. Occasionally a larger dose might have been given with benefit. The advantage of administering the hypodermic of scopolamine and omnopon, especially in nervous and apprehensive patients, is indisputable.

Difficulties at Operation.

To operate really successfully under novocaine requires more precision, neatness, and surgical skill than under general anæsthesia. A rough and clumsy operator could never succeed, except in frightening and giving considerable pain to his patient. Perhaps the most vital point to remember is the exact limits of the area of anæsthesia. For this the closest coöperation with the anæsthetist is essential to prevent the patient suffering unnecessarily. There are also certain characteristic minor difficulties which practice can alone render familiar. For instance, following the cutaneous incision, the underlying tissues never look normal owing to a peculiar œdematous and mucoid appearance of the fat and muscle. To this may be superadded an unnatural blanching of the same structures if adrenalin is used with the novocaine solution. These masking and deceptive appearances may result in anatomical errors being made until the operator is familiar with them.

Again, the non-relaxation of muscular tissue is bound to hamper the operator both in his speed and manipulations. In reference to speed, my average time for a Bassini's radical cure of hernia is 15 to 20 minutes, but is increased through the difficulties already mentioned to 25 to 30 minutes under local anæsthesia.

Special Post-operative Complications.

These may be divided under two headings: (1) Local; (2) General.

1. *Local complications.*—In this group reactionary hæmorrhage must be mentioned. I met this complication in a small percentage of cases operated on, although the proportion was always higher than with general anæsthesia. The hæmorrhage was never alarming nor serious, but varied from an extensive ecchymosis of the skin around the incision to a fair-sized hæmatoma in the cellular planes. Reactionary hæmorrhage always occurred in novocaine anæsthesia to which adrenalin had been added, the hæmostatic properties of the adrenalin being so effective that it occluded temporarily even the smaller-named arteries and veins. The occlusion obviously was due to vaso-motor constriction, and not to thrombosis, as I have often seen the blanched gaping ends of the small arteries pulsating, but showing no vestige of clot in their lumina. Eventually the vaso-constriction passes off, with the liability to reactionary hæmorrhage from the smaller-named vessels unless

ligatured There are two ways to prevent the possibility of this complication firstly, to withhold the adrenalin altogether This is certainly the safest method to avoid reactionary hæmorrhage It is a curious fact that primary hæmorrhage in the incision is far freer with novocaine alone than with a general anæsthetic The alternative remedy is to rub any probable sites of small named vessels to promote hæmorrhage with a view to applying a ligature to each unruly point discovered

Another phenomenon that appeared in practically all the cases operated on was a serous discharge from the incision This usually ceased about the seventh or ninth day In itself the discharge is unimportant as regards the future scar, except possibly when Michel's clips are used In these wounds the cutaneous margins are approximated so closely that no serous exudation can escape Serum collects in the field of the operation, and is further increased by osmosis from the neighbouring tissues by the salts of novocaine and adrenalin remaining in the tissues after operation In time the tension produced along the line of clips results in the Michel s clips being torn out or displaced The mechanical irritation produced, together with the fact that it is impossible to swab the incision with iodine owing to the presence of the steel clips, may result in sepsis of the wound at a later date The palliative remedy of removing a clip or two does not enhance the beauty of the scar It is far better not to use Michel s clips at all The last local complication to be mentioned is the presence of intense pain in the site of the operation which comes on some hours after the operation

2 *General complications* —Alleged insomnia was so common among my patients that it was proverbial for each patient to state next morning that he had not slept a wink The nursing staff had special orders to look out for insomnia, but the general rule was for patients to sleep for several hours the night after their visit to the theatre Intense headaches were also noted in a few cases Rather severe pain was often complained of in the lumbar region, especially with inguinal operations The theatre table was usually blamed for this symptom, although localised nerve shock may explain this more accurately Thirst as a symptom was frequently present during the actual operation, whereas flatulence appeared equally commonly on the following day

Retention of urine was far commoner after novocaine anæsthesia than after similar operations performed under a general anæsthetic, the frequency of the retention depending partly on the roughness of the surgeon in handling the parts

Reference must be made to chest complications During the years 1918-19 there was quite a long series of cases with coughs and bronchitis at Haslar Hospital following general anæsthetics It was partly to avoid chest phenomena that I adopted local anæsthesia so frequently Whether the years mentioned were especially prone to coughs and colds I do not know, but the number of chest complications under novocaine anæsthesia were almost as great as those that followed general anæsthesia An interesting but curious post-operative symptom was the appearance of a definite, but slight tint of jaundice in the conjunctivæ The jaundice set in always on the second day after the operation and occurred in at least 30 per cent of cases It eventually disappeared at the end of the week It never extended to the skin nor other mucous membranes The fæces were of normal colour, whilst bile pigments could never be found in the urine

The pathology of the condition requires investigating as only two similar cases followed general anæsthesia

Points in Relation to Special Operations

Lastly, there are two or three operations that require special mention In performing radical cure for hernia no painful stimuli need be felt by the patient until the neck of the sac is reached Any pulling on the neck almost always produces a momentary painful sensation for the patient The pain is never unbearable, and can be greatly reduced by gentle handling In operating for varicose veins it is doubtful whether the addition of adrenalin is a help to the operation Comparatively large veins, even an internal saphena, are so reduced in size by vaso constriction that some doubt may be expressed as to whether a small branch is being dealt with instead of the original vein to be operated on For hæmorrhoids novocaine anæsthesia cannot always be relied upon to give perfect anæsthesia To this must be added another handicap the non relaxation of the sphincter ani

Medical Societies.

ROYAL SOCIETY OF MEDICINE

SECTION OF PATHOLOGY

A MEETING of this section of the Royal Society of Medicine was held on April 20th Professor W **BULLOCH** the President, being in the chair, when Dr J A **MURRAY** demonstrated charts and sections of three New Growths from the Rabbit with which Autologous Transplantations had been carried out The bearing of the results on the treatment of cancer was discussed

Dr W W C **TOPLEY** read a paper on The Site of Formation of Antibodies and Dr H **LYON SMITH** one on Direct Hæmolysis a Test for Bacterial Toxins and for the Quantitative Estimation of Bacterial Vaccines

The Ætiology of Appendicular Concretions

Professor S G **SHATTOCK** made a communication in which he gave the results of the systematic examination of 25 concretions, the examination being carried out by delamination under water the concretions had at no time been allowed to dry When an arbitrary centre of the size of a hemp seed was reached this was cradled in glycerine between slide and cover glass, and studied microscopically In no instance was any nucleus present, the centre being of the same kind as the rest, and consisting of the undigested residues of plant tissues In two or three the number of stiff pericarpal hairs (like those in flour and oatmeal) was notable, but in no instance were they sufficient to constitute a nucleus after the manner of the oat hair concretions sometimes met with in the colon In no example were any particles of steel or of the enamel flaked from cooking utensils present The absence of these was opposed, therefore to the suggestions that had been put forward in regard to the ætiology of appendicitis in general—viz , that its increase was due to the introduction of enamelled ironware or of the milling of flour by means of the cylindrical rollers of steel now almost universally used An examination of the contents of 100 appendices taken from subjects over 40 years of age, and of 25 from those between the ages of 15 and 25 dying from causes unconnected with the appendix, gave equally negative results in this respect In a few of these small fæcal pellets were met with, which might be regarded as appendicular scybala Such appeared at times to furnish the starting point of concretions The ætiology of concretional formation, the speaker thought, resolved itself into neuromuscular faults of the appendix, a matter of much interest in regard to ectasia and constriction of the œsophagus, stomach, and intestine The entry of fæcal material into the appendix was presumably helped by the contraction of the cæcum upon its contents, whereas the exit depended upon the appendix alone

The factor of mechanical kink might be viewed as an exceptional one, since in concretional forms of appendicitis the organ retained its usual curvatures As to roller milled flour itself, the finest was passed between as many as 13 pairs of revolving steel cylinders yet Professor Shattock had found that no inorganic iron could be chemically demonstrated in it The skiagraphy of concretions after being taken out of the excised appendix, and not allowed to dry, or while still in the excised organ, the speaker found, gave results too variable to prove a negative in clinical application If the deposition of calcium carbonate and phosphate in the stercolith was at all pronounced, a laminated picture was equally so; but if little, the picture was so faint that such a concretion would certainly escape observation in the living body. If the appendix, again, happened to lie behind the cæcum the picture would be obscured by the contents of the latter.

SECTION OF ELECTRO-THERAPEUTICS.

The Mackenzie Davidson Memorial Lecture.

A meeting of this section of the Royal Society of Medicine, held on April 16th, was devoted to hearing the first lecture of the foundation established to perpetuate the memory of the late Sir James Mackenzie Davidson, delivered by Sir Ernest Rutherford, F.R.S. The chair was occupied by Dr. A. E. Barclay, the President of the section.

Sir Ernest Rutherford opened with a warm eulogy of the work done by Sir James Mackenzie Davidson, both in the direction of rendering the whole matter of radiology a subject of greater scientific precision and dependableness, and in elevating it to the position at which it has arrived as a much-requisitioned speciality. He said its followers had now arrived at a parting of the ways: the old haphazard methods, inseparable from a laborious emergence, would no longer suffice if real progress was to be made. Hitherto there had been no systematic teaching of the subject, but individual workers had surmounted the difficulties, and had acquired by much labour a working knowledge of the physical as well as the medical side. He referred with great satisfaction to the establishment by the University of Cambridge of a diploma in radiology and electrology, for which some 30 students in London had already entered. Until the scheme was well established it would be well, he thought, to institute instruction in the subject at two or three convenient centres. Lectures were now being given in London and Cambridge.

The Effects of Radiation on Matter.

The second part of the lecture was devoted to an exposition of Sir Ernest Rutherford's views on certain aspects of the effects of radiation on matter. The effects of X rays in various treatments were similar, in many respects, to those of the beta and gamma rays of radium, but in some cases radium was preferable on account of its ease of concentration on a particular region. The effects of X rays were probably not due to the rays themselves, but to the power possessed by the radiation to eject from matter electrons at a prodigious speed. Some years ago Mr. C. P. R. Wilson, of Cambridge, devised a method by which the trail or track of the ejected electrons could be traced and photographed, and the lecturer exhibited the technique. He compared it to the tracing of the track of a tornado by the path of destruction it left. To secure these remarkable pictures the rays were passed through a gas super-saturated with water vapour, and the electron-path was marked by a chain of minute water droplets. He considered that the rays possess the power of chemical dissociation of a fairly close chemical combination, like water; and that they also have the power of association or recombination, and he entered with attractive detail into his reasons for this view. The effects seen in water could safely be regarded as occurring in the human body when the rays were applied to it, except that the amplitude would be very much reduced, and not every part would be hit by the electrons. The main problem of radiology was to find out the conditions under which the rays passing into tissue would destroy the cells or the foreign organism, with the minimum of danger to healthy cells. Possibly the radiation might, in the case of a few organisms of disease, have the power of differentiating between the injurious cell and the healthy one; and he thought it ought not to be altogether impossible, by the introduction of certain salts or certain solutions into the patient, to produce chemical reactions which would not occur normally. Some such process seemed a condition of further definite advance in the therapeutic use of the rays. He hoped there would continue to be carried out earnest study of the subject, and that the coöperation between the physician, chemist, and physicist would be even more intimate than heretofore.

Cordial thanks were accorded to Sir Ernest Rutherford for his lecture, on the proposition of Sir Archibald Reid, seconded by Dr. Thurstan Holland.

SOCIÉTÉ DE THÉRAPEUTIQUE DE PARIS.

Severe Gout.

At a meeting of this society on March 10th, Dr. Guelpa showed a case of very severe Gout on the way to recovery. The patient was a woman, aged 34, who had suffered from the disease for the last ten years. When she first consulted Dr. Guelpa last November she presented almost complete ankylosis of the hips and knees, less advanced ankylosis of the shoulders, elbows, and feet, and some limitation of movement of the vertebral joints. Both hands showed a dislocation inwards of phalanges on their metacarpals, and both wrists showed an ulnar semi-dislocation. In the right hand the dislocations were more marked than in the left. Owing to the advanced ankylosis of the hips and knees the patient was unable to sit down and could only walk with difficulty. The following treatment was adopted. The patient was purged for four days in succession, and during this time was deprived entirely of food. She was then given an almost exclusively meat diet for four days. In addition muscular exercises were ordered, consisting either in walking chiefly uphill or in mechanical exercises. A drink was prescribed containing five or six drops of phosphoric acid in a glass of boiled water. At the end of a month considerable improvement had taken place and the starvation period was then prolonged till the sixth day, and the purges were given every two days with a beneficial result. Photographs and skiagrams taken at the commencement of the treatment were shown to prove the gravity of the attack and the remarkable improvement produced by the treatment.

Dr. G. Leven also showed a case of Severe Gout which had been cured for ten years. The patient was a man, aged 63, who had suffered from gout from the age of 18 to 53, the attacks becoming worse each year and being complicated by angina pectoris and intercostal neuralgia. At the commencement of treatment in 1909 he had complete loss of power in both hands and feet and there was a large tophus in the left elbow. The weight was then 101·2 kg. An almost complete cure was effected by diet without any drugs in the course of two months. The weight was now 89 kg.

The Treatment of Oxyurids by Intestinal Irrigation of the Sulphurous Spring Water of Luchon was described by Dr. F. H. Pelon, who alluded to the recent communication by Dr. Leven on the treatment of oxyurids by eau d'Enghien.[1] He attributed the beneficial action of the water to a slight extent to the sulphuretted hydrogen, and to a greater extent to the sulphites and sulphides, but mainly to the sulphur which was present in a natural state in the water. Although he regarded intestinal irrigation as the essential part of the treatment for oxyurids, he considered that ingestion of sulphurous water was also beneficial, as it had an undoubted action on the worms living in the small intestine, where fecundation took place.

Two cases of Fistula in Ano cured by Local Applications of Carbon Tetrachloride were reported by Dr. Goubeau, who said that the method might be tried with advantage before surgical intervention.—Dr. Jacquemet and Dr. Goubeau enumerated the following therapeutic uses of carbon tetrachloride, which Dr. Jacquemet had studied since 1906: 1. In surgery, in which it was a first-class antiseptic. It could be used for preparing the surgeon's hands and field of operation in a solution of iodine 1 g., CCl_4 100 c.cm. For protecting the surgeon's hands a solution of 1 g. of indiarubber in 40 c.cm. of the iodine solution was employed. It could also be used for keeping instruments and for the disinfection of infected wounds. 2. As a parasiticide. 3. In dermatology for the treatment of seborrhœa, pityriasis, acne vulgaris, and acne rosacea, either alone or with equal parts of xylol or ether.

Dr. Crespin and Mlle. Athias read a paper on Autohæmotherapy in Anæmia. In cases where normal horse serum and other measures had failed the method had produced considerable improvement in 48 or even 24 hours with a moderate and sometimes a considerable increase of red cells and occasionally of the leucocytes. Only a small quantity of blood was required:—viz., 5-10 c.cm. in adults and 3-5 c.cm. in children. In most cases a single injection was sufficient and it was only exceptionally that a second or third was needed. In the case of anæmic infants whose blood could not be obtained, their mother's blood was injected. It was a remarkable fact that the injections were only successful when the mother was markedly anæmic, no results being obtained when she was plethoric. That was due to the fact that the blood of anæmic persons contained active hæmatopoietic substances, the power of which was probably exalted by passage *into the subcutaneous tissue*

---

[1] The Lancet, March 6th, p. 553.

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION

A MEETING *of this association was held at 11, Chandos* street, W , on April 20th, Dr HELEN BOYLE in the chair

Dr LOUISA GARRETT ANDERSON, formerly chief surgeon at the Military Hospital, Endell street, gave an account, illustrated by lantern slides of the work at that hospital from 1915 to 1919 She stated that the surgical work fell into three groups In 1915 to 1916 large numbers of head wounds were received, and fractured skulls with every kind of complication, were treated , in 1916 and 1917 compound fractures of thigh were numerous, *while in 1918 a fine series of* penetrating wounds of joints—especially the knee joint—were admitted She emphasised the valuable results obtained by the use of bipp, which was first tried in 1916 It was used afterwards for a large number of cases of compound fracture and always with the best results It replaced *other* disinfectants It minimised the ward work enormously, as cases which previously had been dressed twice or thrice daily were left undisturbed with bipp for a week or more *It apparently altered the prognosis of* cases, and shortened the time of treatment in hospital Over 26 000 men passed through the hopsital, and 7000 operations were performed, 300 beds were set aside for orthopædic cases The speaker discussed the advance in the treatment of fractured thighs and wounds complicating joints By disciples of Sir Robert Jones—notably Major M Sinclair and Major J Everidge—the treatment of these cases had been revolutionised In 1914 a case of compound fracture of the femur *was a source of infinite anxiety* to the surgeon and great suffering to the patient, it meant dressings at frequent intervals, drainage tubes constant operations *for the* removal of sequestra, and, at the end of months of misery, a weak leg, considerably shortened, possibly with a stiff knee The modern treatment of thorough preliminary investigation and cleaning, followed by the application of bipp to the wound, suspension on a net bed or a Balkan frame, a well fitted Thomas splint, and early movements of the knee, was incomparably better The evolution of technique for dealing with penetrative wounds of joints *was equally striking In 1918 it was not uncommon to* regain a full, or almost full, range of joint mobility

CARDIFF MEDICAL SOCIETY

A MEETING of this society was held on April 13th, when Dr R PRICHARD read an interesting note on some cases of Fourth Disease (Dukes) which had come under his notice

Dr JEFFREY JONES showed a patient with Nodules on the *Legs, Hands, and Arms The first symptoms* had been œdema of the legs followed by nodules, and later by a similar condition *in the hands and arms* The patient was an Arab Dr Jones discussed the diagnosis and considered the following possibilities—syphilis, beri beri, and leprosy The Wassermann was negative there was no anæsthesia and there were no organisms on microscopical examination after removal of a nodule The Lister Institute of Preventive Medicine reported it to be a "spindle celled sarcoma of vascular *origin* '—During the discussion which followed Dr D J HARRIES *suggested the possibility of Baghdad* boil, and advised looking for Leishman Donovan bodies He stated that this condition may resemble a *growth on section*

Mr GEARY GRANT reported cases of Sarcoma of the Ulnar Nerve removed without *ill effect and of Secondary* Suture of the Ulnar Nerve He also showed a skiagram from the case of a man suffering from a nodule fixed to the skull Egg shell crackling was present, the patient having been previously operated upon for sarcoma of the humerus —During the discussion which followed it was generally agreed that the growth was from the meninges and that *removal* was not possible

Mr H G COOK showed a case of Sprengel's Shoulder and a specimen *of Ureteral* Calculus

Mr A W SHEEN showed a skiagram of a case of Sprengel's Shoulder and another *of a* Fractured Patella in a man who went on playing football for 20 minutes after the injury

HUNTERIAN SOCIETY —At the annual general meeting of this society held at the School of Oriental Languages (London Institution) on April 28th, the *following* were nominated by the council as Honorary Fellows Sir Archibald Garrod, Sir W Arbuthnot Lane, Sir George Newman

Reviews and Notices of Books.

INDUSTRIAL MEDICINE AND SURGERY

By H E MOCK, B S , M D London and Philadelphia W. B Saunders Company 1919 Pp 846 42s

THE habits and customs of society are so closely intertwined that changes affecting any part of the whole must influence the rest The productive work of the world with a steady and increasing insistency is *being gathered more and more within the walls of great* industrial establishments, expensive and specialised plant increases in complexity year by year, even agriculture, the greatest *of* all industries, is rapidly becoming wholly dependent on factory made machinery Where the plant is, there are the workers gathered together in ever increasing numbers, here they live that portion of their lives which makes them of economic value to the State, here they enjoy health or contract illness and sustain accidents which limit their usefulness The questions for the medical profession *to day are Does it know how this illness is contracted?* Does it know how to reclaim the disabled to be again wage earners? Does it know how life is lived within factory walls? We have in these columns previously pointed out the urgent need for industrial medical service, and *declared that in this country we are falling* behind in developing such a service

Production is the urgent need of the moment, production *depends on the health and activity of* labour Apart from labour itself, no portion of the community could do more to help than the medical profession if its industrial service were organised first, for selecting workers for their work—for preventing a C 3 person from overstrain at a process *needing* A 1 *labour, or an* A 1 worker being wasted on a C 3 process, secondly, for maintaining in health and vigour those selected, and lastly, *for returning* to useful work those whose health or limbs are damaged in the battle of life The need, as judged by news and by publications which reach us, seems to be appreciated more in America than in this country Here attention has been concentrated on *diseases peculiar to industry*, such as lead *poisoning*, anthrax, and dust phthisis , and there is a tendency to lose sight of the forest while paying attention to those few small and comparatively insignificant trees Yet we are aware that great advances were set on foot by our Ministry of Munitions, and that we possess an Industrial Fatigue Research Board We hope that our medical literature will soon show signs of industrial activity Meanwhile, the pages *of the Anglo American Journal of Industrial Hygiene* are chiefly occupied by American authors Quite recently we drew our readers' attention to a Government report issued by Washington on the medical and surgical care of industrial workers,[1] and we have *now before us a book* in which the industrial position is *plainly set forth* by Dr Mock, an industrial medical officer, who tells his own experience, *both startling and convincing*. He points out how the profession is ignorant of industrial work, its scope and possibilities "*Recognition of the relationship between* conditions in industry and the health of the people will become more and more essential in the teaching *of medicine* in the *future*." All that the profession knows, all it can do, should be at the disposal of the worker To morrow the State may have to enforce it, to day the privilege lies with the employers to ensure it, and the privilege carries with it economic gain and a *contented personnel* Dr Mock makes no claim he cannot support, and he gives figures which prove that through one branch of medical work alone—the careful examination of all applicants for work—after the cost of *entire* medical service was deducted, there accrued *to the employer an annual* profit of over a quarter of a million dollars through examining 118,900 applicants After that all is profit the improved health and greater efficiency , better time keeping; the elimination of septic injuries and lessened compensation; the increased output resulting from fitting round pegs into round holes; the sickness stayed by timely treatment; the accidents prevented by safety-first methods. Yet, again, the experience of a large railway corporation is quoted, who found that "the reduction in time lost due to immediate and competent medical care more than offsets the expense of this work." The wonder is that employers are so slow in developing and adopting this most paying proposition.

---

[1] The Studies of the Medical and Surgical Care of Industrial Workers Public Health Bulletin No 99 1919 Washington

The doctor in the past has waited for the patient to come to him. More and more is preventive medicine, with its great vision of health, pointing out that the doctor must be brought to the patient before he is a patient. Certainly the surgeon must be brought to the injured instead of the injured to the surgeon. In battle this may be impossible; in industry only organisation is needed and a surgeon on the spot. "Preventive surgery is a direct outgrowth of human maintenance in industry." Industry provides the means by which the health of the community can be easily controlled in groups, the means by which the gospel of health and the prevention of disease can be disseminated in every home in the land. Neglect to use means by those who possess them, neglect to employ talents, always has its nemesis. If employers continue to neglect their opportunity now as they have done in the past, let them not blame others than themselves when remorseless fate under whatever guise dethrones them. Ignorance of the facts will be no excuse, for the facts are known. All have stood aghast at the casualties of war, but after giving chapter and verse for his conclusion, Dr. Mock writes: "It may be safe to assume that the total number of amputations suffered by men in Pennsylvania's army in the field of war will be considerably less than the total number of amputations suffered in Pennsylvania's industries over an equal period"; and this industrial "list of honour" is constantly with us, and extends beyond the field of surgery over the whole region of medicine.

Dr. Mock's book deviates, as he points out, from the usual character of a text-book; it sets forth the reasons for, and the practicability of, industrial medicine and surgery. He tells what can be done from experience of what has been done; and he tells how it has been done; how the lives and limbs of workers can be conserved; how those, who through daily strife are disabled or maimed in health can be reclaimed to comfort, contentment, and efficiency. At times he writes rather as the apostle of a new creed than as a scientific teacher; for the spirit of the pioneer is upon him, the spirit of one who has found a great productive land, and would have others follow where he has blazed the trail.

Dr. Mock is essentially an industrial surgeon. He feels the great need to industry of preventive surgery. He is at his best when telling of his own work and his own organisation. What could be more convincing than his advocacy of iodine as first-aid treatment for every abrasion or cut however slight, with absolute prohibition of washing or other manipulation, when supported by such figures as these:—

—	1912.	1913.	1914	1915	1916
1. Total number of accidents.	2693	4970	5971	7760	7925
2. Total number of infections (95% hands).	772 (28·6%)	710 (14%)	655 (10%)	586 (7·5%)	610 (7·6%)
3. Infected cases where iodine was used in department and then reported at once to doctor.	No record.	18	16	5	10
4. Infected cases where iodine was not used in department but reported at once.	,,	28	28	12	12
5. Infected cases where these rules were not observed.	,,	668	611	569	588

He has also devoted much attention to the tuberculosis employee, to his detection and treatment. Particular stress is laid on after-care for the arrested and apparently cured, who he maintains should not be recommended for farm-work, for which they are not physically fit, but should be returned to their own skilled industry through the medium of model factories attached to every State sanatorium. Six years ago in this country action on these lines was advocated; the war intervened; we still wait. Compensation, insurance, and medico-legal phases are dealt with on broad principles; excellent cases are given, and valuable instances are quoted. The author desires compensation extended. "It can be irrefutably assumed that if compensation was extended to include all sickness, as proposed in health insurance, it would not only advance industrial medicine, but all medical practices. In fact, a beneficent system of socialised medicine would rapidly ensue."

When, however, Dr. Mock turns aside to speak of industrial medicine, of ventilation, of feeding, dust hazards and poisons, he is less convincing. He writes rather as one who has got up his subject, and we frankly consider he would have done better to have called his book Industrial Surgery and omittted all else. The book is well planned, but could have been usefully shortened by eliminating repetition and avoiding a tendency to classify duties of officers and methods of procedure. Much of this reads like efforts at appearing precise where no real precision is attained—efforts which the author was evidently too busy to edit sternly. A valuable and comprehensive bibliography is given at the end, and this is followed by the one blot in the book—an imperfect index. We thank Dr. Mock for finding time to give us this book, and recommend it to all members of the profession (too few, we fear) who take an interest in the social aspect of their work. Readers of this book will see there is work in industry for the medical profession to do.

INDUSTRIAL NURSING.

By F. S. WRIGHT. New York: The Macmillan Company. 1919. Pp. 179. 6*s*. 6*d*.

EACH advance in modern medicine has been associated with a corresponding advance in the nursing profession. One European war coinciding with the discovery of anæsthetics led to the evolution of the trained hospital nurse. More recently personal application of preventive medicine brought into existence the health visitor. And now another great war which threw a searchlight on the conditions of industrial life has developed the position of the industrial nurse whose work is distinct from that of either of her predecessors. In this last case the nurse is forging ahead of the doctor, and is often installed in charge of the ambulance work at industrial establishments to which no medical officer has yet been appointed.

A book has been published in America by F. S. Wright, an industrial nurse, setting forth the importance and wide scope of the work. She states truly that "industry needs a good nurse with a knowledge of methods of social work in addition to familiarity with methods of public health nursing." The position is discussed from the point of view of small factories, and therefore much which in a full organisation belongs to welfare supervision is included, but nothing is referred to which an industrial nurse may not find herself having to face in daily work. First-aid for cases of accident and the ambulance-room work have been the prime movers in creating the industrial nurse; but, once established, her sphere of work immediately expands, for an industrial establishment is an ideal organisation through which to carry out preventive medicine for adults. Medical cases as well as injuries gather to the ambulance-room; early symptoms which represent the curable stages of disease are seen here. Four groups of cases come under observation—minor injuries and more serious injuries, minor sickness, and more acute illness. In order to deal with them friendly relations have to be established with foremen; and a first-aid ambulance corps has to be organised and taught the importance of non-interference. From this beginning education in health widens out; and education is required, for "we cannot move people along the road of progress one bit faster than they see the need of being moved." The work does not consist in meeting a series of great emergencies, "as in reality the spectacular seldom does and never should happen", it consists rather in searching out what "is wrong, either in the health or habits of the worker, in his work itself, or in his surroundings or associates" The processes in the factory must be understood, the home conditions of the employees must be studied Coöperation must be established with outside agencies, medical practitioners, hospitals, dispensaries, charity organisations, health officers, creches and welfare centres, school medical officers, labour exchanges, religious bodies, lodging and boarding house keepers Health talks in the dinner hour, informal gatherings of nursing mothers, home visitation of the ailing, organisation of recreation, supervision of the canteen and starting domestic cookery classes, all come within a nurse's sphere of activity Then there are careful records to be kept of accidents and illness, and investigations to be made from these records into causation and prevention The condition of the sanitary accommodation is her care, the cloak room provision and means for drying wet garments must be looked after, the equipment and use of the washing accommodation call for attention

Each of these matters is discussed in practical detail in the book now under notice Employers, and we include mine owners, who have not appointed a nurse should read this book, it will be of value to the nurses whom they will forthwith engage Factory medical officers will find therein much useful information Industrial nurses already at work will obtain from it inspiration for furthering their daily activities and clear instruction as to the means to adopt

THE SOCIAL WORKER

By C R ATTLEE, M A London G Bell and Sons, Ltd 1920 Pp 286 6s,

THIS volume is the first of a series of handbooks on social service published under the ægis of the University of London Ratan Tata Department of Social Science and Administration The volume before us forms an introduction to the series As stated by the author in the preface, it is an attempt to show what are the qualifications and training desirable in the social worker Beginning with the social reform movement of Robert Owen, the author makes a concise introductory survey of the field of social service from the early Victorian era down to the recent developments of the trade unions, the coöperative societies, and the friendly societies In so doing he justly points out that the rise of democracy has changed the outlook of the social worker Formerly social work was done *for* the working classes, now it is or should be done *with* the working classes in a spirit of comradeship and not of superiority The most valuable contribution to social service which this book makes is the insistence on a right point of view The spirit of goodwill is the keynote of service

In writing an introductory volume of this character it must be difficult to decide how much to include and how much to leave out The author has, perhaps wisely, left out most of the detail, and has contented himself with a broad outline drawing Modern researches into such problems as those of poverty, factory conditions, crime, and social psychology are barely touched upon Doubtless they will be adequately dealt with in the later volumes of the series We trust also that these later volumes will give us a subject index which the present volume lacks

We recommend the book to all students who are embarking on a course of study in social service Its perusal may help to widen the horizon of medical practice

POPULAR CHEMICAL DICTIONARY.

By C T KINGZETT, F I C, F C S London Baillière, Tindall, and Cox 1920 Pp 368 15s

Mr Kingzett's aim has been to produce a popular dictionary to serve as a general work of reference for practical chemists as well as for the larger body of the public who take an interest in the subjects and substances which he describes Incidentally, the book is designed to be an advanced companion to a previous book entitled "Chemistry for Beginners and School Use" For the latter purpose it may be regarded as entirely successful The verbal accuracy of the dictionary is remarkable, we have only been able to find the single word *Kieselguhr* incorrectly given The author's claim to be a satisfying guide to those of the younger generation who are in search of knowledge is less convincing He does little more than hint at the wider views of chemistry and physics revealed by such moderns as Curie, Rutherford, and Mackower. The illustrations in the book, all precisely and accurately rendered, depict files, tripods, flasks, wash bottles, and pieces of wire gauze, while the subject of catalysts is dismissed in half a page devoted chiefly to platinum black, and the indestructibility of energy is mentioned without an explanation of its gradual degradation into its lowest form of heat To the word salvarsan is added 606 in quotation marks, but the aspiring reader would like to learn the name of Ehrlich and to hear of the 605 compounds elaborately investigated before he made his great discovery Altogether, the book as it stands may be described as a safe but unimaginative vade mecum We trust that in his next edition, which is certain to be soon required, the author will feel free to let himself go a little in the realms of chemical adventure There is one trifling error of judgment, in that two proprietary articles, and two only, are named in the text

PULMONARY TUBERCULOSIS

Second edition, revised and enlarged By MAURICE FISHBERG, M D, Clinical Professor of Medicine, New York University and Bellevue Hospital Medical College Philadelphia and New York Lea and Febiger 1919 With 100 engravings and 25 plates Pp 744

THE brevity of the interval between the appearance of the first and second editions of this book is the measure of its popularity It is well deserved Indeed, it would be difficult to find a more compact yet comprehensive review of the subject It has not, however, been brought quite as much up to date as the year of publication demands The author has, no doubt, been obliged to omit references to much recent work of doubtful value, but it is disappointing to find the names of Jacobæus, Brownlee, and Morriston Davies absent from the index of authors consulted The subject of surgical operations for phthisis, for example, is dismissed in less than two pages In his preface to this edition the author claims to have revised nearly every chapter and to have rewritten several A comparison with the first and second edition shows that he has adopted the plan of printing in italics statements of cardinal importance

New chapters on tuberculosis of the pleura and on pneumothorax have been added, and the differential diagnosis has been given more space than before Several additional plates have been inserted, illustrating the pathology of the disease, and many of the radiographic plates have been replaced by new ones The experience gained by the author between the publication of the first and second editions with reference to influenza and tuberculosis adds appreciably to the value of the present edition His view in this matter appears to be that only the mortality, not the morbidity, of pulmonary tuberculosis has been increased by the recent successive waves of influenza, and he has not seen a single case of tuberculosis engendered by influenza He possesses the courage of his convictions to a degree rare in the writers of text books In many matters he is dogmatic, but as his dogmatism is usually supported by well sorted evidence it is excusable and even helpful His verdict on such doubtful remedies as tuberculin is always incisive, and he refuses to be impressed by the volume and pretensions of the literature of any given remedy He ridicules the complexity in which the administration of tuberculin has become involved, and he refers with a smile to the practice of some authors who use "logarithmic tables for their calculations, as if they were dealing with an exact science" In his opinion tuberculin is at present given chiefly for its psychic effect—a comment which may apply to other drugs prescribed for chronic maladies

MECHANICAL DENTISTRY.

A Practical Treatise on the Construction of the Various Kinds of Artificial Dentures. Seventh edition, revised. By CHARLES HUNTER. London: Crosby Lockwood and Son. 1920. With 102 illustrations. Pp. 266. 5*s*.

THIS book has been before the dental profession for many years, and has proved of great value to those engaged in acquiring the art of mechanical dentistry. It is a little disappointing to find that the present edition has not been brought up to date, but even with this defect it is still a most useful manual.

JOURNALS.

Parasitology. Edited by GEORGE H. F. NUTTALL, F.R.S. Vol. XII., No. 2. March, 1920. C. F. Clay: Cambridge University Press. 15*s.* net; yearly subscription, £2 5*s.*—The number opens with a short note on Intestinal Helminths in Indians in Mesopotamia, by Charles L. Boulenger, who had the opportunity of examining the stools of 1180 individuals, chiefly dysentery cases. *Anchylostoma* and *Necator* are shown to be the commonest parasites (18·5 per cent.). The author calls attention to the fact that *Hymenolepis nana* is the commonest tapeworm met with in Indians, and that *Trichostrongylus* is a much commoner parasite in man than is generally supposed.—In the paper On some Nematode Parasites of the Zebra, the same author describes five species of nematodes, three of which are new (*Cylicostomum zebræ*, n.sp., *C. montgomeryi*, n.sp., and *Craterostomum tenuicauda*, gen. et sp.nn.). The author finds that the nematode parasites of the zebra consist of several species known in the domestic equines, as well as others which are only found in zebra.—In the article on a Parasitic Spiral Organism in the Stomach of the Cat, R. K. S. Lim describes a new spirochæte living in clusters within the lumina of numerous ducts and glands of an apparently normal cat's stomach. The organism, which morphologically resembles the genera *Spironema* and *Treponema*, is 4 to 8μ long with regular closely-set spirals. They were not seen in any other part of the intestines except the very beginning of the duodenum, or in any other organ. The mode of infection remains unknown. Attempts at cultivation of this organism failed. A somewhat similar organism was previously found by Bell and Ruquet in the stomach of the dog.—The article, On a Filaria, *Loa papionis*, n.sp., parasitic in *Papio cynocephalus*, by C. H. Treadgold, deals with a new filaria found in the yellow baboon imported from the French Guinea to Paris. Of the 55 animals examined, only 13 were infected, of which 10 yielded the adult forms of parasite (*Loa papionis*), while 12 contained the larval stages (*Microloa papionis*). In one case neither ♂♂ nor larvæ were present. The host does not resent the presence of the parasites; at the autopsy the internal organs appeared healthy, and even in the most extensively infested animals a distinct degree of eosinophilia was never encountered. The adults (*Loa papionis*) were usually found in the subcutaneous tissues. In the peripheral circulation the larvæ are invariably present at night, being less numerous or absent in the daytime. Three specimens of *Loa papionis* were found to be infected by bacteria. The paper contains a good description and figures of adult and larval stages of this parasite, which is also morphologically compared to *Loa loa*.—The paper On Fahrenholz's purported New Species, Sub-species, and Varieties of Pediculus, by G. H. F. Nuttall, contains a very severe criticism of the methods usually employed in the description of Anoplura. According to the author, all the species of *Pediculus* described by Fahrenholz, which are derived from different races of man and monkey, are synonymous with *P. humanus*, races *capitis* and *corporis*. All the characters upon which are based Fahrenholz's descriptions are thoroughly examined and proved to be valueless, as they are usally met with in a single lot of *P. humanus*.—The article On the Two New Gregarines: *Allantocystis dasyhelei*, n.g., n.sp., and *Dendrorhynchus systeni*, n.g., n.sp., parasitic in the alimentary canal of the dipterous larvæ, *Dasyhelei obscura*, Winn., and *Systenus*, sp., by D. Keilin, contains a description of different stages of the above-mentioned gregarines. *All. dasyhelei* differs from all the other known gregarines in possessing elongated sausage-shaped cysts of about 140–150μ long and only 20μ wide.—The paper on Spermatogenesis in *Ixodes ricinus*, Linn., by E. Nordenskiöld, deals chiefly with the cytological changes in the spermatids whilst developing into the full-grown spermatozoa, the latter, in the ticks, being of very aberrant shape, differing considerably from the typical flagellate form.—Mallophaga from South African Birds, by G. A. H. Bedford, contains a description of *Neomenopon pteroclurus*, n.g., n.sp., taken from a sand-grouse in the Transvaal, and of *Machaerilæmus plocei*, n.sp., collected from a passerine bird in Pretoria.—The number is concluded with a short note on Body-lice under Summer Conditions in Mesopotamia, by P. A. Buxton. It contains an account of seasonal variation in the number of lice in Mesopotamia, where during summer months the lice are very scarce, and towards the end of November suddenly become numerous. As this increase in lousiness coincides with the re-issue of winter under-linen, which is stored through the summer in ordnance dumps, an erroneous supposition prevails among the sanitary officers that the lice survive the summer as eggs in the stored clothing. The author points out the incorrectness of this view, as it is well known that the duration of the egg period is very short.

La Medicina Italiana. Istituto Editoriale, Milan. L.2.50.—There seems to be an influx of new Italian medical journals lately, and the first issue of this monthly periodical came from the press at Milan last January, consisting of 78 pages. The entire front cover is taken up by a photographic reproduction of Professor Augusto Murri, of Bologna, of whom there is a eulogistic biographical notice from the pen of Professor Antonio Gnudi. The collaborators of the journal are very numerous, and include most of the well-known names in Italian medicine. The papers in the present issue contain: Disease and Individuality—a Diagnostic Formula, by Professor L. Zoja; The Diagnosis of Petechial Typhus, by M. Segale; The Relationship between Infection and Immunity, by Professor E. Centanni; and the Cultivation of Tissues in Vitro, by G. Levi. A large section is devoted to discussion of present-day medical topics and news.

Il Mondo Medica. Piazza St. Croce, Roma. L.1.50.—This monthly journal entered its second year on Jan. 1st, 1920, having changed its somewhat unwieldy large quarto for a crown octavo, with a new artistic and semi-allegorical cover containing a hand grasping a flaming torch surmounted by a shield bearing a reproduction of the historic wolf suckling the infants Romulus and Remus. The editor is Professor Michele Pietravalle, Parliamentary deputy. The January issue contains articles by Professor Fichera on a case of Friedreich's disease; by Dr. Gianturco on surgical lesions of the kidneys and urinary passages; by Professor Arena on cystinuria; by Dr. G. Poppi on adenoids. Compulsory insurance against illness is discussed in an editorial with the report of the Commission appointed to deal with this subject. It may be noted that while the Commission fully recognised that a complete system of reform should include orphan and lunatic asylums, the majority were of opinion that it was not suitable to attempt too large a measure of reform at first.

L'Ospedale Maggiore. Via Ospedale, Milan. L.1.—The size of this illustrated monthly review has been increased from a small post octavo to a small quarto of about 40 pages. The editors are Professor Icilio Boni and Professor Enrico Ronzani, with Avv. Mario Rolla as editorial secretary. In the July, 1919, issue there is an editorial on the condition and salaries of nurses in England, referring to the report on this subject by the committee of the College of Nursing; no independent comment, however, is made on it. In the last number which reached us there are articles on Diabetes, by G. Vigevani; on Pulmonary Cancer, by D. Cassarini; in the August number on Tuberculoma of the Optic Thalamus, by Ugo Botelli. The illustrations are not numerous but are distinctly good.

Archivos Rio-Grandenses de Medicina. Orgao da Sociedade de Medicina de Porto Alegre. Numero 1, January, 1920.—We have received the first number of the *Archives of Medicine of Rio-Grande*, the official organ of the Society of Medicine of Porto Alegre. The journal is intended to serve as a means of communication among members of the profession in the south of Brazil, and to stimulate discussion on topics of general medical interest. It is the aim of the editors to provide a medium for recording the results of research carried out in Rio-Grande, and to collect papers on clinical and pathological subjects which would otherwise remain unpublished. No very striking original work appears in the present number. Perhaps the most interesting contribution is a short article by Professor Roger on the Rôle of the Portal Vein in Pathology. The effects of ligature and obstruction of the vessel are discussed, and the author inclines to the view put forward by Le Play and Ameuille that cirrhosis of the liver is secondary to infection of the spleen.—In a paper on Toxic Effects following Arsenical Medication in Syphilis Dr. Ulysses de Nonohay advances the theory that adrenal insufficiency is responsible for many accidents. This insufficiency is said to be due either to the virus of syphilis or to the depressing effect of arsenic on the gland. The conditions for which the suprarenal is called to account are varied, since they include urticaria, œdema, hæmorrhages, lepto-meningitis, meningitis serosa, paralysis, blindness, syncope, and epileptiform convulsions.—The remainder of the journal is concerned mainly with detailed studies of clinical cases by various professors of the Porto Alegre clinic. Interspersed between them are notes on treatment, medical aphorisms from various sources, and an epitome of current medical literature.

THE LANCET.

LONDON: SATURDAY, MAY 1, 1920.

Hospital Principles.

THE announcement by the Minister of Health in the House of Commons on Wednesday of last week that he had given his consent to the establishment of a municipal hospital at Bradford may have created a flutter in the world of hospital administration, for it has been hailed by the daily press as a kite showing the direction of the wind in the high places where decisions are made. The decision certainly shows which way the wind is blowing in Bradford. But this was hardly in doubt before. The wind has for long blown from the bracing quarter of municipal administration in that great worsted emporium of 250,000 inhabitants. It is not the war or post-war conditions that have killed the voluntary system in Bradford. Its Royal Infirmary, an old and insufficient fabric, has long been inadequate for the needs of the city, but funds for rebuilding on a new and better site were coming in none too fast before the war. Since then the Poor-law hospital of St. Luke, itself standing better than the infirmary, has been much enlarged and ennobled as a military hospital. The total beds of both are needed, and urgently needed, for general medical and surgical cases. Here is a situation in which a municipality of advanced views, already accustomed to the support of medical institutions on a large scale out of local rates, was sure to intervene. Dr. ADDISON describes their scheme for the establishment of a municipal hospital as the one practicable method of providing the institutional accommodation necessary to meet the needs of the city. "I decided as I did because it was the only way of meeting the necessities of the case," were his actual words. The shouldering of the whole hygienic burden by citizens for citizens is the task chosen of its own free will by Bradford, and endorsed without question by the central authority with a wise acquiescence in the decision of local opinion.

While it would be hard to over-estimate the significance of Bradford's lead, it would be perverse to see in Dr. ADDISON's attitude any change of policy in regard to voluntary hospitals elsewhere. No particular perspicuity is needed to guess that the Advisory Committee over which Lord DAWSON presides will be willing to suggest more power for local sanitary authorities in providing hospitals where such are needed and for coördinating the work of all the institutions lying within their borders. And it is equally certain that the Health Services Bill, when it is drafted, will provide the statutory powers for putting such recommendations into effect. But good faith and common sense alike will ensure the survival of any voluntary unit willing and able to take its place in the scheme. Regional survey must form the basis of coördination; there can be no talk of the creation of new units when sufficient material of all kinds, whether of bricks or hands or brains, cannot be had for love or money. And regional survey must take account not only of the community's needs in medical, surgical, and special beds per 1000 of the population, not only of the existence of trained personnel, the medical and nursing staffs and the great body of able lay administrators, but also of the local type of social service. A community trained by heredity to give of its superfluity in money or kind or personal effort will not be coerced into the penny-on-the-rates or the twopence-a-week-on-wages mould. Local habits of philanthropy are woven into the very fabric of society and cannot be unravelled without destroying the material. The ideal will be to secure, in the first place, that each area gets the hospital which it deserves, and local freedom of action will assuredly be sanctioned in so far as it results in the common good. Liberty can and will be retained under central guidance.

The cardinal principles justifying local autonomy are efficiency and avoidance of overlapping, and on these two things the Ministry of Health has insisted and remains adamant. In London, which always constitutes an exception, although an exception larger than most rules, it is agreed that there should be institutional coöperation, in return for which State-aid will have to be granted, and, for the present, on a large scale. The voluntary principle is as firmly rooted in London as the coöperative principle in the Midlands or the municipal principle in the north. To take a single example. Of the 200 infant welfare centres in London 154 are carried on by voluntary agencies, and although the focus of each is well defined its sphere of influence is often nebulous enough. The voluntary principle has many and conspicuous virtues and only one besetting sin, the deplorable failing of overlapping. Hardly any Government subsidy would be too large to offer as the price of reformation in this respect. The municipal principle never overlaps; on the contrary, it is apt to become the dog in the manger. The medical officer, who is a whole-time civil servant, jealously restrained from consultation with fellow-practitioners of his art, is too apt to lose contact with the larger professional view to the narrowing down of his outlook and interests. Research has as yet never blossomed as freely on the municipal soil. In these things there is a lesson for the wise and consolation for the faint-hearted. Medicine has obtained its greatest triumph in the foundation of a Ministry of Health and in making its voice effectively heard in the counsels of the nation. Let its disciples offer the twin fruits of efficiency and economic effort, and their gifts will not be spurned.

Scientific Cardiotherapy.

THE application of exact methods to the clinical investigation of disorders of the circulatory system has greatly enriched our knowledge of both the physiology and pathology of the circulation, and in consequence the diagnosis of cardiac disease has been rendered more exact and more rational. We publish on p. 954 of this issue of THE LANCET an interesting paper by Dr. I. HARRIS, in which an attempt is made to apply the increased knowledge thus acquired to the problems of the treatment of heart disease. Dr. HARRIS commences his article with the rather striking statement that, "in spite of the progress in cardiology within recent years the treatment of heart disease is as unsatisfactory now as it was 20 or 30 years ago." Many of our readers may not be prepared to subscribe to such a sweeping statement, since the recognition of the value of large doses of digitalis in the treatment of auricular fibrillation is alone sufficient to render it an exaggeration. At the same time a careful perusal of Dr. HARRIS'S suggestive article would seem to show the need for a careful examination of the modes of action of the various drugs used in diseases of the heart and vessels in the light of the newer knowledge of these conditions if we are to obtain the maximum benefit from their use. It is important to recognise that there are two distinct aspects of the circulation to consider both in health and disease—namely, the purely physical or hydrodynamic and the strictly physiological or vital. The physical conditions involve the consideration of the pressures in the different parts of the circulatory mechanism, the amount of input into the cavities of the heart at each diastole, and the actual force of systole. The vital aspects of circulatory problems concern the rate of the heart's beat, the time relations of systole and diastole, and the adaptation and adjustment of the blood flow to the needs of the organs and to varying conditions. In his search for some rational and scientific basis on which to assess the value of drugs in cardiac disease and to provide criteria or standards for their effective use, Dr. HARRIS has selected the intracardiac pressure as the most suitable means. He points out that the electrocardiograph offers an easy and accurate method for measuring the lengths or duration of systole and diastole, and he suggests that these data afford a means of estimating the relative intracardiac pressure. He assumes that a relatively long diastole in relation to a short systole signifies a high intracardiac pressure. We may refer our readers to the original paper for the reasoning on which this assumption is based, but it is of interest to note that as a result of his observations Dr. HARRIS differentiates two distinct types of heart failure, with different and characteristic symptoms and intracardiac pressures. The first of these he finds chiefly in young people with moderate hypertrophy of the left ventricle and an arterial blood pressure never unduly high, and becoming lowered when failure of compensation occurs. The heart is dilated in such patients, and the pulse-rate is high. Œdema is common and readily yields to treatment, while the arteries and peripheral circulatory apparatus in general are normal. In such cases sudden death is rare. Dr. HARRIS finds that the most characteristic feature in the different phases of the heart beat is a considerable shortening of diastole. As the pulse becomes quicker the diastole becomes shorter and shorter, while the length of systole remains nearly the same as in the normal condition. Dr. HARRIS argues that the intracardiac pressure in such cases is low, and he sees in the symptoms of this condition a protective adaptation, the rapid action serving to obviate more serious consequences. The engorgement of the veins and œdema which may appear in these cases he regards as secondary effects of an otherwise beneficial process due to the fact that the total output in rapid heart action does not compensate for the smallness of the output of a single contraction. In this type of case the adaptation which occurs is in the interest of the heart muscle, and the intracardiac pressure is low. The indication for treatment is to strengthen the heart muscle, and any cardiac tonic drug may be of use.

Dr. HARRIS'S second type of heart failure is one which occurs in patients with marked hypertrophy of the left ventricle or sclerosis of the heart muscle associated with high arterial blood pressure. Angina-like pain is common and there is no fall of blood pressure, even when general œdema supervenes. The pulse does not become accelerated and sudden death is common. By contrast with the other type the sclerosis of the arteries and general pathological condition of the peripheral circulatory apparatus are very marked features. Examined by the method suggested by Dr. HARRIS, it is to be noted that there is no increase in the pulse-rate when failure occurs in these cases, and the length of systole in relation to diastole remains the same as before the onset of failure, while the intracardiac pressure also keeps at a high level. Dr. HARRIS maintains that the adaptation which occurs in this type of failure is in the interest of the peripheral circulation, with secondary results often to the disadvantage of the heart itself. He points out that the high arterial blood pressure and the increased force of the individual beats are adaptations designed to overcome an increased peripheral resistance. Dr. HARRIS believes that the most striking clinical feature of a typical case of this kind is the absence of jugular engorgement, even when there is marked general œdema. He supposes that this is due to the long diastole, which allows ample time and space for the veins to empty themselves into the auricles. He claims that there can be no question of back pressure as a cause of the œdema, and suggests that it is more likely to originate from forward pressure. This part of his contention is perhaps a little obscure and is possibly open to criticism, as also is his dictum that the indication for treatment in such cases is to give drugs which may lower the intracardiac pressure, but which interfere as little as possible with the peripheral resistance.

The concluding portion of Dr. Harris's article deals with the effect of certain drugs on intracardiac pressure. This section is of particular interest, since in it are examined in some detail the actions of various drugs upon the heart's functions. Digitalis is so valuable in the treatment of many forms of cardiac embarrassment that it is, perhaps, not sufficiently recognised that its effects are complex and that they are not invariably beneficial. The fact that it depresses conductivity is now generally admitted, and its use in conditions of "blocking" is contra-indicated; indeed, it may induce this condition if injudiciously employed. Dr. Harris refers to certain effects of large doses of digitalis shown by the electrocardiograph, which suggest its discontinuance in any case in which they appear. He finds that medium doses of digitalis increase the intracardiac pressure, whilst large doses lower it considerably, and he brings forward some observations which show that strychnine has a definite action upon the frequency of the heart beat, lowering it in many cases and having a favourable influence on some forms of irregular heart action. Dr. Harris is of opinion that his observations prove that digitalis is indicated in cases which show his first type of cardiac failure, whereas it is to be avoided in those of the second type. In the latter he thinks that caffeine is a useful drug owing to its effect in lowering intracardiac pressure without decreasing arterial tension. At the same time he admits that many patients cannot take it for any length of time owing to its action on the nervous system; and under these conditions he recommends atropine. Even the occurrence of œdema he does not regard as indicating the use of digitalis in this class of case, and he advises puncture of the legs and the use of adrenalin. Dr. Harris's paper raises many points of interest for discussion, and puts some known conditions in a new light. On these grounds alone it should be of interest to our readers, and may well stimulate further observations on similar lines to establish, modify, or controvert his contentions.

◆

An Antimalarial Campaign in Palestine.

The 21st Army Corps of 70,000 men lay for nearly a year (November, 1917, to October, 1918) in Palestine, occupying the course of the river Auja from its mouth across the Valley of Sharon to the foot-hills. Several deaths from subtertian malaria occurred in December, and 20 cases of malaria were reported weekly from two brigades during January, the patients coming from an area covered with orange-groves and provided with numerous wells; they came from units camped near the wells, and were all of them men in billets near the mouths of the wells. It was clear that malaria threatened to be a great danger, and in January, 1918, Major E. E. Austen, D.S.O., was directed to make a mosquito survey of the country. The mean day temperature was below 60°F., and it was found that anopheles were not breeding in the pools and streams, but in the warmer wells, and that adult anopheles, eager to bite, were sheltering in these wells. The wells were dealt with, and malarial infections became for the time a negligible cause of sickness. It had been intended to make an April offensive, which, however, was postponed owing to events in France. Clearly, then, the 21st Corps must remain in this area during the summer, and the prevention of malaria became at once the most important problem.

The corps was situated in one of the most malarious districts, and unless extensive works were undertaken malaria would destroy the corps. The area abounded in mosquito breeding-places, marshes and pools and sluggish streams overgrown with weeds and brushwood. The natives could not live in the valley in summer as malaria was rife; much less could the new comers. Young anopheles larvæ were found on April 12th in open water. All these things had been considered beforehand. On the day the advance was counter-ordered a survey of the whole area was put in hand, and in a few days drainage works were commenced under the direction of the chief engineer, General R. P. T. Hawkesley, to whose energy the successful result is largely due. The area slopes very gently to the west. It is seamed with small ravines, in which are many springs, and drained by sluggish streams often overgrown. These ravines had to be cleared of brushwood, to be banked, to be cleaned out, and to be kept clean, so that water could always run away. The marshes had to be drained, one of them could not be naturally drained, but an old tunnel through the barrier was found and utilised. It appeared that this tunnel harboured hibernating anopheles. They were killed with two cylinders of chlorine gas—with them were killed frogs, snakes, and small birds. Large numbers of men were put on this work—the sum total of which may be numerically expressed as 222,480 men-days—and the cost is estimated at £40,000. What did this expenditure achieve? Not so much, certainly, as if the work had begun one or two months earlier, but that was impossible, plans in February being so different. But, as we have seen, no time was lost; the best was done with the time there was. In spite of it, malaria did occur. The first attacks seemed due to the appearance in June of swarms of anopheles which had been hibernating, and which appeared while mean temperature was low and before free breeding in open water had begun. The drainage works had begun too late, so these June mosquitoes were able to breed, but by August the works undertaken had become effective, the pools and so on had been drained, and larvæ and adult mosquitoes had fallen to a minimum, instead of rising to the normal maximum appropriate to the season. It is pointed out by Colonel E. P. SEWELL and Major A. S. M. MACGREGOR (who planned this campaign, and give a lucid account of it in the *Journal of the Royal Army Medical Corps* for February and March), that the very best work, limited to the English area, could not wholly prevent malaria, as some of the valleys led up to the Turkish lines and could not be denied to mosquitoes, though at great risk oiling was often carried out right up the Turkish wire. In fact, mosquitoes came over from the Turks and infected the British advanced posts.

Malaria did occur in the summer, as had been expected by all the experienced—10 per cent. of strength was lost in the 21 weeks of summer to Sept. 19th; the corps was not destroyed, as undoubtedly it would have been had it been forced to remain through the summer without anti-mosquito measures in its previous position. It must not be forgotten that General Headquarters had helped by sending the 21st Corps two malaria diagnosis stations, whose services were invaluable. The striking success of Lord ALLENBY'S coup in September, 1918, was in the main due to his skilful plan and the valour of his troops. But that his troops were there to carry out his plan is in great part due to the excellent work done in the 21st and other corps throughout his army, by the Royal Army Medical Corps to keep the troops free of the malarial infections, which have long lain like a pall over the country and prevented its profitable development. And how small was the relative cost of prevention! £40,000 to protect 70,000 men, to prevent 60,000 cases of malaria; 12s. per man for prevention. Quinine for the treatment of each case would not have cost less than 20s., and the deaths that would have occurred if the epidemic had broken out would have been a tragic loss. We are indebted to the authors of a valuable paper.

◆

THE COMPLIMENTARY DINNER TO SIR GEORGE MAKINS.

MAY we remind our readers that this dinner will be held on Monday, May 10th, at the Wharncliffe Rooms, Hotel Great Central, at 7.30 for 7.45 P.M., and add that there is no leader of our profession, who has more clearly merited a public compliment from his colleagues. Any of Sir GEORGE H. MAKINS'S friends, and any who have reason to know the great value to the public as well as to the profession of the services which he has rendered, will be welcome. They are asked, if they have not already done so, to notify Mr. C. MAX PAGE, 134, Harley-street, W. 1, of their intention to be present. This information is essential in order that seating arrangements can be made. Payment for the dinner (1 guinea, not including wine) to be made at the Wharncliffe Rooms. Sir CUTHBERT WALLACE will preside, and no tickets will be issued.

Annotations.

"Ne quid nimis."

LONDON AS A POST-GRADUATE CENTRE.

THE organisation of medical post-graduate education in London has now been coördinated by the Fellowship of Medicine upon the lines laid down at its foundation meeting. One of the original aims of the Fellowship was the establishment of a central bureau from which information respecting post-graduate facilities in Great Britain could easily be obtained (see THE LANCET, Jan. 4th, 1919, p. 26). This position has now been reached, and the Fellowship has become a recognised centre, at which inquiries from medical men in all parts of the world are received. Most of the correspondents wish to map out courses of work in London and the provinces. Those who not only write but arrive are growing in number, and visitors from the continent and from overseas have now acquired the habit of proceeding to the offices of the Fellowship within a few hours of their arrival. In short, the energies of a year's hard work are bearing gratifying fruit, and the post-graduate students who attended the London hospitals and schools last summer have mostly gone home with a satisfactory account of their reception. Many of the men coming over to-day from the Dominions and the United States come with personal introduction to the Fellowship from previous students, and the reputation that London has suffered under for inhospitality—a reputation which has done great harm to post-graduate work in this country—is being corrected.

The last issue of the weekly Bulletin of the Fellowship shows the possibilities of the post-graduate work as now coördinated. A student, assisted by the daily programme, can plan a course of study in any department and at almost any hour of the day, granted that the promises of the schedule are kept. Curiously enough these advantages are not being fully appreciated by the medical men in London, or even by the home country. Whilst the courses in the metropolis are attracting post-graduates from overseas and from the continent, they have not yet aroused the enthusiasm of men who are within easier reach of the facilities offered. Not long ago, when many correspondents reflected upon the obvious dearth of post-graduate facilities in London in comparison with those offered, for example, in Germany, we had no suggestion to make. Now we advise all our readers to write to the secretary of the Fellowship of Medicine, 1, Wimpole-street, London, W. 1, for a copy of the Bulletin, that each may see for himself how far the special department of work in which he is interested is met by the arrangements of the Fellowship. If he is in any doubt as to his methods of procedure he should make inquiries, and certainly if he considers that any promises are not kept he should notify the laches at headquarters.

LEAD POISONING AND COMPENSATION.

THE recent trial before Judge Mulligan, K.C., at the Holt County Court (Norfolk), of a claim for compensation under the Workmen's Compensation Act, raised in an instructive manner the difficulties which may arise in cases of alleged lead poisoning. The medical evidence, while in harmony as to the existence of lead ingestion as a toxic factor at one period in the man's history, was at variance over its bearing on his present condition.

The applicant was a man of 23, who had been employed at Melton Constable Station, from April, 1911, to January, 1919, in painting engines, using white lead and sand-paper. In December, 1915, he had an attack of lead poisoning, as certified by the late Dr. J. Skrimshire, who attended him for six weeks. For a while after this he was given other work to do, but returned to the painting in June, 1916, when he developed a second attack of lead poisoning after scraping the inside of carriage roofs. On this occasion he was laid up for four days. He had a third attack in January, 1919, which totally incapacitated him until the following March; since then he had only been able to do light work, and he now stated that he suffered from weakness in the arms and legs and pain in the abdomen. The railway company had accepted the man's statement and the doctor's certificate of lead poisoning, and had paid him compensation for loss of work during the three attacks specified. But on being sent to see Dr. Barfoot Mills, of Norwich, in March, 1919, Dr. Mills certified that he was not suffering from lead poisoning, and the compensation was accordingly stopped.

When the case came on for trial Dr. Mills gave evidence that he had found no sign of lead poisoning, but that the man was suffering from neurasthenia and weakness of the heart, and that the best thing he could do was to get back to work. The idea of lead poisoning had been so drilled into the man's mind that he put all his troubles down to that cause. In cross-examination Dr. Mills admitted that if Dr. Skrimshire was right in certifying the man to be suffering from lead poisoning he would assume the neurasthenia to be due to that. Dr. H. J. Starling, assistant physician to the Norfolk and Norwich Hospital, who examined the applicant on March 24th last, found him in a very excitable condition, with disordered action of the heart but no organic disease. The condition of the abdomen was not due to actual pain, but to nervous contraction in anticipation of pain. There was no sign of lead poisoning, but if the conviction remained in the man's mind that he was suffering from it, the probability of his cure was very slight, and the best thing for him was work. Dr. R. T. Hales, of Holt, certifying factory surgeon, said he had examined the man, but found no evidence of lead poisoning, though from his story he presumed he was convalescing from an attack of lead poisoning. On the other hand, Mr. S. H. Burton, consulting surgeon to the Norfolk and Norwich Hospital, said he examined the plaintiff on Dec. 16th last, and again on the morning of the trial, and considered that his condition was compatible with the story he gave of his history. At the present time the man was neurasthenic, and in Mr. Burton's opinion light work in the open would do him good. Although he found no trace of lead poisoning present, yet he considered that the excited action of the heart from which he suffered was brought about by the man's lowered tone due to the lead poisoning.

The judge, in summing up, commented on the great importance of the case, lead poisoning being one of the diseases which under the Workmen's Compensation Act were placed under the same category as accidents, and compensated accordingly. There was, he said, a considerable difference of opinion in the medical evidence which he had heard, but he found as a fact that Dr. Skrimshire was right when he said the man was suffering from lead poisoning, and he accepted without hesitation the evidence of Mr. Burton that his present condition was due to the lead poisoning. The doctors had all agreed in saying that the plaintiff was neurotic and that he would not recover so long as he brooded on his illness. He could not go back to painting, but there was plenty of other work suitable for him. He awarded the plaintiff 12*s.* a week, to commence from Nov. 1st, with costs.

The problem presented to the judge in this case was a difficult one, and in our opinion he decided wisely and judicially. Upon the evidence put before him it would seem clear that the applicant had certainly had three attacks of lead poisoning, and that he had quite rightly been paid compensation for these. All the medical evidence pointed to the fact that the present condition of the man was one of neurasthenia with excitable or disordered action of the heart. The judge accepted the view that the man's condition was a sequel of his attacks of lead poisoning, and at the same time recognised that light work of a different character would be beneficial to him morally, physically, and mentally. We may express the hope that enlightened decisions of this kind may become the rule in cases where neurasthenia figures in compensation cases after accident, injury, or industrial disease.

EPSOM COLLEGE: THE RISE IN EXPENSES.

THE general increase in salaries and in the cost of living, as well as the alterations in the retiring grants to masters, on the lines of the Superannuation Act of 1918, have compelled the Council of Epsom College to increase the school fees. The increases will date as from September next, and will apply to all boys, whether entering the school for the first time or at present there. For the sons of medical men the fees will be increased from 70 guineas to 100 guineas; for the general boarders from 80 guineas to 120 guineas; and for day boys from 25 guineas to £40. We can quite understand that the Council had no alternative but to make these increases in the school fees, for the loss on the working of the school for the past year has amounted to £3779 15*s.* 10*d.* The charitable contributions in aid of the Foundation cannot, of course, be expended in defraying any of the expenses of the school beyond paying for the education of the foundationers.

CATHETERISM OF THE URETER IN CALCULOUS ANURIA.

IN the *Progrès Médical* of March 20th Professor Léon Thévenot, of Lyons, has selected for commentary two cases of calculous anuria treated by a method which, so far, has been seldom employed—ureteral catheterism.

A man, aged 35 years, was admitted into hospital on May 31st, 1909. He was addicted to alcohol, and had suffered for years from attacks of renal colic, during which he did not pass urine. After an attack in 1907 he passed two pieces of gravel of the size of a small pea. An attack of renal colic with anuria began three days before admission, and only 50 g. of urine were passed on the previous evening. The left kidney was painful, but not palpable. Two days after admission the patient was cystoscoped. On the left side the ureteral catheter was arrested at a distance of 6 or 7 cm. from the orifice of the ureter; on the right side nothing abnormal was noticed. On the following day the patient passed a large and irregular calculus, and the emission of urine became normal. On performing cystoscopy again the left ureter was found permeable.

In a second case a man, aged 47 years, was admitted on May 3rd, 1911. Since 1893 he had suffered from attacks of renal colic, especially on the left side, and hæmaturia, and had passed phosphatic calculi. In 1903 lithotrity was performed for stone in the bladder. A large calculus was removed from the right kidney. In March, 1914, he was readmitted for complete anuria, following renal colic. A catheter was passed into the left ureter as far as the renal pelvis without encountering resistance. On the following day 2½ litres of urine were passed. Radiography did not show any calculus in the left kidney. In June, 1915, he had an attack of anuria lasting two days, and passed 80 g. of urine on the third day. The ureteral catheter was passed after momentary arrest at a distance of 6 cm. from the ureteral orifice and yielded a discharge of 1 c.cm. of fœtid pus. It was passed as far as the renal pelvis, from which turbid urine flowed. In one and a half hours the patient passed 407 g. of turbid fœtid urine.

How ureteral catheterism acts is not easy to say, because the pathogenesis of calculous anuria is not fully understood. The catheter may push back a calculus which is obstructing the mouth of the ureter, or it may give rise to contractions which cause the calculus to be expelled into the bladder. On the hypothesis that the secretion of urine is reflexly inhibited, the catheterism may reflexly re-establish it. Whatever be the explanation it is efficacious. Out of 40 recorded cases it was successful in 32. In the early days of the anuria Professor Thévenot thinks it is absolutely indicated. The injection through the catheter of boric solution or glycerine seems to have a favourable action in re-establishing the secretion of urine, which reappears immediately or in a few hours. Some writers have seen the anuria recur after removal of the catheter; therefore it ought to be retained for a certain time. If catheterism fails it may be repeated several times, as long as all signs of uræmia are absent. If the surgeon does not see the patient till about the fifth day catheterism may still be tried, but if it fails nephrotomy should be immediately performed. After the fifth day, or if the slightest signs of uræmia have appeared, Professor Thévenot recommends nephrotomy. Should catheterism be performed on one or both sides? It has rarely been performed on both sides, and the extra benefit derived does not seem to be marked. Professor Thévenot thinks that this procedure uselessly prolongs the operation. It should be reserved for cases of bilateral calculi or of failure of unilateral catheterism. Usually it is sufficient to catheterise on the side of the morbid phenomena, whether definite renal colic or dull pain. In numerous cases it has not only relieved the anuria, but led to the elimination of the renal calculus and the avoidance of nephrotomy.

THE BEST TYPE OF ARTIFICIAL LEG.

THOUGH an artificial limb must obviously conform to certain definite requirements, there is still margin for variation in the materials used in its manufacture. Moreover, the adjustment of the conflicting claims of great strength and light weight must be made with some reference to the expense involved. It is interesting to note that the weight cannot be reduced below a certain optimum figure—estimated at 4 to 6 lb.—otherwise the limb becomes difficult to control under unfavourable conditions such as heavy gusts of wind or long wet grass. In a letter addressed to Sir Arthur Stanley, Mr. Edred M. Corner, surgeon in charge of the Artificial Limb Department at St. Thomas's Hospital, states that over 90 per cent. of men with above-knee amputations experience greater benefit from the light metal artificial limbs used at this hospital[1] than from the wooden limbs provided by the Ministry of Pensions, and he pleads for the official issue of a metal leg. The main difficulty appears to be the expense, since not only is the initial cost higher, but the repairs are more difficult and costly, though, it is claimed, less frequently required. On the other hand, men can apparently do more work with less fatigue, and acquire balance and control of complicated movements with greater ease with a light metal leg, which is said to be specially useful in hot climates. A suitable leg for above-knee amputations can be turned out in five weeks at a cost of £27. An artificial arm made of light metal is already issued by the Ministry of Pensions, and the official adoption of an approved pattern of metal leg would seem a desirable outcome of the successful experiments at St. Thomas's Hospital.

SECONDARY SYPHILIS OF THE HEART.

ACCORDING to Dr. C. Oddo and Dr. C. Mattei,[1] of Marseilles, in descriptions of the effects of syphilis upon the heart, the tertiary manifestations alone have hitherto received much attention. They point out, however, that the increasing frequency of lesions supposed to have appeared in the tertiary stage suggests that the heart is more often affected in the secondary stage than has hitherto been realised. They report a fatal case of pericarditis in a man aged 54, who presented mucous tubercles of the lips and scrotum. The histological examination showed definitely that the lesions affected the pericardium and that the myocardium was not involved. The study of previous cases shows that secondary syphilis of the heart may assume different forms, some being mild and characterised by arrhythmia only, and others serious and fatal. The diagnosis is based on the history of the disease, the clinical course, the Wassermann reaction, and especially the effect of treatment. The prognosis should be as guarded as that of secondary syphilitic meningitis. Specific treatment, preferably by mercurial preparations, should precede the use of cardiac tonics. Salvarsan should be employed with caution, as it is very liable in such cases to give rise to cardiac collapse and pulmonary œdema.

NITROGEN IN WAR AND PEACE.

IN connexion with the scheme now on foot in this country for the manufacture of nitrates from the air at Billingham-on-Tees, involving the outlay of something like 5 millions of money by a powerful combine, the following note taken from the *Economic Review* (April 21st) on Chilean nitrates production is of interest:—

> *Chilean Nitrates Production.*
>
> The Chilean nitrate fields cover approximately 90,000 hct.; their resources are estimated at over 100 mill. t. Only the fields to the north of Antofagasta are being worked.
>
> The exploitation of the southern deposits was long hampered by the Government's refusal to build railways to that district, the object being to prevent over-production. The nitrate is obtained in surface workings; iodine is extracted as a by-product. During the war, production increased enormously. The export rose from 40 mill. quintals (46 kg.) in 1914, to 64·8 mill. in 1916; in 1917 it was still as much as 62·2 mill. Before the war the bulk of the export went to Germany. (*Korrespondenzbl.*, March 23rd.)

The Billingham-on-Tees site in county Durham was selected by the Government a year before the Armistice was declared with the view of increasing the output of nitro-explosives, and to some extent buildings, machinery, and plant were begun. The scheme, started for war purposes, will now, it is to be hoped, be developed for peace issues. It should be an important acquisition to British agriculture, and the promoters, we understand, are assured of the economy of the process and convinced of a large output of nitrate for fertilising purposes in the future. The fixation of nitrogen from the air on a large scale clearly means great national advantages, whether it be an answer to war or peace calls. We pray for the latter. In either case it is desirable to be independent of Chilean supplies.

---

[1] Bulletin de l'Académie de Médecine, March 30th, 1920.

LEPROSY IN INDIA.

Sir William Vincent has introduced into the Imperial Legislative Council a Bill to amend the Indian Lepers Act, which follows, as far as possible, the recommendations of the Conference on the leper problem held in Calcutta in February under the auspices of the Mission to Lepers. That Conference, the most important gathering of the kind held in India, had before it recent information regarding the treatment of lepers, both from the public health and the medical points of view. The findings of the Conference were clear and far-reaching. Proof having been given that leprosy is communicable in a variety of ways, the only way to rid a country of the disease is to isolate and to keep under supervision and control all persons afflicted with it. This has been done in Sweden, Norway, Iceland, and Germany with the most satisfactory results—namely, the practical stamping out of the disease. In the Philippines, which were quoted frequently at the Conference as an example which India should follow, there has been within the last few years a reduction of leprosy to an extent which suggests that in a few years it may disappear altogether from those islands, and in the Hawaiian Islands a similar state of things prevails. To secure such results, however, the complete isolation of all leprous persons has to be insisted on. In the asylums or settlements to which all such persons are relegated the utmost care is needed to keep the sexes apart and, as far as possible, to discourage the marriage of persons afflicted with leprosy, inasmuch as the fecundity of lepers, especially of females, is far in excess of the normal. Where it is impossible to secure this isolation the spread of the disease may be checked by removing from lepers all children as soon as possible after birth, because while the disease is communicable it is not necessarily hereditary—the children of lepers are not born lepers, nor need they become lepers if the precaution of removing them from leprous surroundings is taken early.

Unfortunately, in India it is not possible, for various reasons, financial among others, to act completely upon these findings: the compulsory segregation of all lepers is not possible, so the Act will confine itself to pauper lepers—namely, those who are found begging in the streets and actively endangering the health of the general public. The definition of leper received close attention from the Conference, and has been amended to include all leprous persons, and not only those suffering from ulcers, sores, or other cutaneous lesions, since the discovery was made that the disease is communicable at all stages in a variety of ways, but particularly by mucous nasal discharges. These steps having been taken, it follows naturally that there will be a great increase of lepers under detention, and provision will have to be made for their housing and treatment in properly equipped asylums, hospitals, and dispensaries. There are Government asylums in most of the provinces, and while nothing but good can be said about these institutions, the best results hitherto secured in the treatment of lepers have been in the institutions conducted by Christian missions. Here is clearly indicated an agency with which the Government may coöperate for this purpose. It is fortunate, too, that in the matter of the medical treatment of leprosy, India, thanks to the efforts of Sir Leonard Rogers and others working in the same field of research, has little to learn. The discoveries that have been made have been put into use in most of the asylums and hospitals with good results. But all existing institutions will be seriously crowded when pauper lepers are cleared off the streets, and steps will have to be taken to provide a staff of medical men with special training in the diagnosis and treatment of leprosy.

MEDICAL REVANCHE.

THE principle of individualism, of which we are reminded by the centenary this week of Herbert Spencer's birth, has little application at the present time. Our Paris correspondent writes that the medical profession in France is becoming restive under the constant discomfort, inconvenience, and hindrance in its work caused by strikes, especially by those involving transport. A spirit of resentment is arising in medical circles against the members of trade-unions, who do not hesitate to sacrifice to their own special interests those of the rest of the community, while at the same time counting on the unfailing supply of medical services. A number of medical societies have suggested an eight-hour working day for medical men, with increased fees for over-time. At a recent congress held at Quimper, the associated medical men of the department of Sud-Finistère decided to refuse to attend patients, rich or poor, in private or in hospital, to-day, May 1st, when the supply of practically all other commodities ceases. They added a rider to the effect that humanitarian considerations are no more binding upon doctors than upon those who hold up trains supplying milk to babes and sick persons. Our correspondent does not say why his colleagues, who are determined on drastic action, should not confine their reprisals in the first instance to the strikers and their family circles. The hardship to patients involved in granting an eight-hour day to the sister profession of nursing has already been felt in Paris, as our correspondent himself testified a fortnight ago.

MEDICAL INSPECTION OF HIGHER-GRADE SCHOOLS.

MUCH good should come of the issue by the Board of Education of Statutory Rules extending medical inspection and treatment to pupils in secondary and continuation schools throughout the country. These rules affect all the children in schools provided by the educational authority, including the pupil-teacher centres and the preparatory classes recognised by the Board for the training of teachers, the junior technical schools and day classes. Any other school or educational institute, whether aided by the local authority or not, may take advantage of the scheme and ask the authority to provide medical inspection and to make arrangements for attending to the health and physical condition of pupils. Educational authorities are requested to consider how far they can avail themselves of the services of private medical practitioners, and a warning is added against the establishment of a special service for domiciliary treatment. Provision must be made for medical inspection of pupils during their first term after admission, and then every succeeding 12 months. Where authorities are starting the work and time is limited, the Board suggests that preference be given to children just admitted or on the point of leaving. In London, where these children have been systematically examined for many years past, no difficulty has been experienced in getting defects treated and preventive action taken, and valuable information will result when the machinery is got going throughout the country. The Board of Education meets half of the yearly expenditure incurred.

BIOLOGICAL CONTROL OF DRUGS.

IN order to secure effective control of certain therapeutic substances, the Minister of Health has appointed a committee to consider and advise upon the legislative and administrative measures to be taken. The committee appointed consists of the following members:—

Sir Mackenzie D. Chalmers, K.C.B., C.S.I. (chairman).

H. H. Dale, C.B.E., M.D., F.R.S., head of department of biochemistry and pharmacology under Medical Research Council.

G. F. McCleary, M.D., medical officer, Ministry of Health.

A. B. Maclachlan, assistant secretary, Ministry of Health.

C. J. Martin, C.M.G., D.Sc., F.R.C.P., F.R.S., director, Lister Institute of Preventive Medicine.

The secretary of the committee is Dr. E. W. Adams, O.B.E., of the Ministry of Health, Whitehall, S.W. 1.

The quality and authenticity of a number of important remedial substances offered for sale to the public cannot be tested adequately by direct chemical means. It is possible, for instance, by the technique of an ordinary chemical laboratory to state that a sample of iodide of potash or of double cyanide of mercury is free from impurity and may be safely administered with the expectation of certain well-known therapeutic effects. The same cannot be said of many of the modern synthetic remedies, and this was so notoriously the case with arsenobenzol in its various modifications and aliases that administrative action was found necessary at the beginning of the war to protect both patients and administrators. Many of the alkaloids and hormones and all the vaccines and immune serums are in much the same position, and the time has now come to ensure the same protection against fraud and error in the case of complicated remedies that we already enjoy in the case of the simpler ones.

A MEDICAL SURVEY AT MIDDLE AGE.

THE annual report for 1918 of the county medical officer of health for the Soke of Peterborough compensates for its late appearance by containing suggestions of a piquant character. The author, in discussing the uniform decline in infant mortality throughout his area, states frankly that it is evident everywhere and "is as marked in areas where no ad hoc measures are taken as in those where thousands of pounds of the ratepayers' money are annually spent." He is evidently distrustful of the results of recent developments in the supervision of the infant and of the school child, for he adds that the nation has "to spend enormous sums on infant welfare, with results that, owing to our ignorance of the laws of heredity and prenatal hygiene, are, to say the least of them, unconvincing." His remedy is the compulsory examination and treatment of persons in early middle age—at or about the age of 40—when the commencing signs of disease which carry off a large number of individuals over 45 are easily detected, and still capable of treatment with comparative ease. There is evidently a little wavering in the author's mind as to whether this measure is all-sufficient or whether it needs special advocacy; for the Ministry of Health is at first blamed for not concentrating on this period of danger, while later caution again raises its head and proclaims that "medical examination and treatment should be provided for all at all ages instead of confining it to the most healthy period of life." Nevertheless, there is much sound sense in the suggestion of a medical stock-taking half-way through what we all hope may be our span of life. How much misery and ill-health might be avoided if a man could be advised in time that his arteries were ageing too rapidly, and that such and such measures should be adopted to maintain a sound body; how much early malignant disease in women might be caught in time and cured; how valuable would be advice and warning as to dietetic indiscretions now no longer trivial in their effects! As to the abstract value of such examination there can be no two opinions. But, having taken the horse to water, can you make him drink? Having, let it be supposed, provided the machinery for his examination at this mature age, will the average man of mature habits subject himself to its beneficent inquisition? In Germany, perhaps; but in this country we can say, with tolerable confidence, No.

THE Graduation Dinner of the University of London will be held at the Guildhall on Wednesday May 19th.

THE Scottish Secretary has appointed Dr. Norman Walker as Inspector of Anatomy for Scotland, a post which he has held in a provisional capacity during the last two years.

Sir Arthur and Lady Newsholme were passengers on the s.s. *Carmania*, which arrived in Plymouth on April 23rd from New York. Sir Arthur Newsholme has in the press a volume of American addresses on "Public Health and Insurance," which is being published by the Johns Hopkins University Press.

WE expect that Sir William Orpen's presentation portrait of the learned and veteran professor of medicine at the University of Cambridge may prove one of the principal pictures at the exhibition of the Royal Academy of Arts to be opened next week. The portrait of Sir Clifford Allbutt, it will be remembered, is the result of a subscription among medical men, and is to be given to Sir Clifford Allbutt alike to mark the general esteem and admiration of his colleagues, and to celebrate his long tenure of the position throughout the war of the Presidency of the British Medical Association. All those who have seen the portrait have admired it both as a likeness and as a dignified and decorative representation of a great man.

THE MEDICAL EXAMINATION OF THE CIVILIAN AERONAUT.[1]

AN explanation of the methods and standards now in use in this country for the examination of applicants for licences as civilian airmen was published, at the end of last week, under the authority of the Air Council. The Dominions and Colonies, who are now about to put into practice the principles laid down in the International Air Convention, have been especially in the eye of the Air Council in issuing a valuable brochure, but all the medical profession, and, indeed, the public, will benefit by learning the careful procedure whereby the intending aeronaut is selected for his dangerous and responsible career.

The pamphlet begins by reference to the

International Medical Requirements for Air Navigation.

An extract from the Convention relating to International Air Navigation, 1919, is quoted, setting out that the requirements are that pilots and navigators engaged in public transport shall be 19 years of age, of good family and personal history, free from mental, moral, or physical defect or hereditary nervous instability, and able to reach the standards required at a general medical and surgical examination and also at examinations into special sense acuity. The International Convention sets out that—

> (1) Every candidate before obtaining a licence as a pilot, navigator, or engineer of aircraft engaged in public transport shall present himself for examination by specially qualified medical men appointed by, or acting under, the authority of the contracting State.
>
> (2) Medical supervision, both for the selection and the maintenance of efficiency, shall be based upon certain requirements of mental and physical fitness. The aeronaut must neither suffer from any wound, injury, or operation, nor possess any abnormality, congenital or otherwise, which will interfere with the efficient and safe handling of aircraft. Nor may he suffer from any disease or disability which renders him liable suddenly to become incompetent in the management of aircraft. He must, therefore, possess heart, lungs, kidneys and nervous system capable of withstanding the effects of altitudes and also the effects of prolonged flight. Further, the aeronaut must possess a degree of visual and auditory acuity compatible with the efficient performance of his duties, and also possess free nasal air entry on either side.

The Convention, further, has provided that for the present each contracting State shall fix its own method of examination until the authorised medical representatives of an International Commission for air navigation shall decide on tests and standards. In order to ensure the maintenance of efficiency the aeronaut is to be re-examined every six months and the findings attached to his original record. In case of illness or accident there is also a re-examination, and no aeronaut may resume duty before being pronounced fit. Moreover, the date and result of each re-examination is recorded on the certificate. Lastly, the Convention provides that each contracting State may raise the standards as they like, but cannot lower them.

The British Methods of Examination.

The pamphlet describes the British methods for the examination of flying men in compliance with international medical requirements. The American Air Service has issued a full and profusely illustrated manual of the national procedure, and it is none too soon that the same is now done in this country. The physical and temperamental suitability of candidates for aviation engaged during the war the earnest attention of British doctors and physiologists, as in France, Italy, the United States, and Germany, and the desire of the Royal Air Force is to issue some pattern of general guidance for the future, having regard to the lessons of the past.

The pamphlet then sets out in paragraph form certain instructions taken verbatim from those issued to the medical officers of the Royal Air Force for the examination of aviation candidates. The special flying tests, which for a long time were carried out separately, fall for examination under the heading of the different systems to which they apply. The mental tests are not included, not because they are considered useless, but rather, it would seem, because it is better to leave their character to the discretion of the examiner; and the same may be said of special reaction time tests or muscle tone tests, which have not been adopted in this country to any large extent because further investigation is needed.

The methods of examination are then carefully described under the headings of family and personal history, age, general surgical examination, general medical examination, and special examinations of the eye, ear and vestibular apparatus, nose, and throat. Under the head of personal history, the following conditions are considered to require special mention:—

> *Head.*—A history of fracture of the skull should definitely disqualify for air work.
>
> *Neck.*—Scars, the result of removal of glands, should not be held as a cause for rejection, but the time which has elapsed since operation, the question of recurrence and signs of tubercle elsewhere, are all points needing attention and examination.
>
> *Chest.*—In cases of perforating wounds of the lungs, any signs of permanent injury to the lung tissue, while not necessarily constituting a cause for rejection, will indicate the need for special care with the tests for respiratory efficiency. A history of empyema, with resection of rib, calls for careful consideration of the cause of the condition and its effect on the lung expansion.
>
> *Extremities.*—Applicants suffering from the conditions mentioned below should not be accepted. (1) Amputation of thumb at carpo-metacarpal joint, (2) amputation of first and second fingers, (3) amputation of hand or arm, (4) injuries or operations leaving marked limitation of movement, (5) amputation of the leg above the knee, (6) operations on the knee joints, which have resulted in such limitations of movement at the joint as to interfere with the proper control of the machine.
>
> *Note.*—Amputations below the knee are not necessarily disabling, provided the movement at the knee joint is free; each case should be considered on its merits.
>
> In addition to the above, injuries which involve the trunks of the larger nerves, resulting in paresis, or which leave scars causing pain or cramp, are sufficient cause for rejection.
>
> *Abdominal operations.*—The fact of an abdominal operation having been performed should not, in itself, disqualify an applicant or airman, provided that no hernial protrusion or marked weakness of the abdominal wall has resulted.
>
> *A history of tuberculous disease* of joints or bones, recent or remote, should disqualify.
>
> *A dislocated semilunar cartilage* may prove a permanent disability, even after so-called successful operative treatment.

In respect of habits, the consensus of opinion is in favour of the strictest moderation in tobacco and alcohol among flying men. Any subject with a tendency to cardio-vascular or nervous instability should therefore be strongly advised in this direction, but gradual renunciation is probably more expedient in most cases than sudden and total abstention. The following is the text of the pamphlet:—

> *Smoking.*—It is recommended that careful record should be made as to whether "non-smoker" or "smoker," and if the latter whether pipes or cigarettes, or both, and whether moderate or excessive. The simplest method is to make a note such as C 10 or P 3—i.e., ten cigarettes or three pipes per day.
>
> *Alcohol.*—Questions under this head should elicit whether teetotaller or "takes alcohol." If the latter the form, e.g., spirits, wines, beer, or cocktails, and the records should give some idea of the average daily quantity.
>
> *Venereal disease.*—Any applicant or airman with a history of syphilitic disease should be deferred, and referred to an expert for an opinion before granting or renewing a licence.
>
> *Sleep.*—Enquiry should be made as to hours of sleep, the occurrence of dreams, nightmares, &c. If sleep is poor questions should be put as to the difficulty of getting to sleep, and the records should show the number of hours slept.

Athletic proficiency and familiarity with unsedentary pursuits will gain marks, as, of course, will a history of previous flying work. The minimum age of 19, as ordained by the International Convention is adopted, but no maximum age is suggested.

We need not put out the details of the general surgical examination and general medical examination, because all those who have to conduct the examination are certain to be familiar with them, but it is interesting to see how valuable the methods of body measurement advocated by Professor G. Dreyer in our columns[2] have proved themselves. It is considered that these methods provide an accurate means of estimating physical proportions, and should be applied practically at each examination and re-examination.

The Examination of the Respiratory System.

The examination methods for discovering the conditions of the respiratory system of aviators may be quoted verbatim:—

---

[1] The Medical Examination of Civilian Pilots, Navigators, and Engineers. London: His Majesty's Stationery Office. 1920. To be purchased through any Bookseller or directly from H.M. Stationery Office. 6d. net.

[2] THE LANCET, August 9th, 1919, p. 227.

(i.) *Condition of lungs.*—Evidence of chronic bronchitis, emphysema, or tuberculous lesions (quiescent or active) should absolutely disqualify an applicant. An applicant should not be accepted as a pilot if the chest expansion as a whole is bad, especially if the deficiency is due to malformation of the chest wall.

(ii.) *Breath holding.*—(Apparatus required: stopwatch and nose-clip.) The subject is asked to expire as deeply as possible (preferably audibly) and then to fill the lungs fully (but not to absolute distension), and to hold the breath with the nose clipped or held. The reason for the audible expiration is that it has been observed that some subjects suffering from stress have lost the power of expiring fully, and a marked shortening of time taken to expire as fully as possible may afford an indication of such loss of power. The time during which the breath is held is noted, and the subject is then asked the reason for giving up. This should be recorded. The significance of the test and the time that is expected must not be communicated, and on no account may any examinee time himself.

Reason for ceasing.—Normally an answer such as "I had to give up," "I felt I should burst," "I wanted to breathe" is given. Subjects suffering from marked disability at altitudes almost invariably return an abnormal answer, e.g., "I became giddy or dizzy," "Things went blurred," "The blood rushed to my temples," "I began to feel squeamish." Where the answer is deemed not to be normal the subject's own words should be given.

The average time the breath is held by the normal fit pilot is 69 seconds, the minimum time being 45 seconds. Generally speaking, a man who does not hold his breath 45 seconds should not be admitted as a pilot. As a matter of experience it will be found that very nearly all such cases will be rejected on medical grounds, apart from this test. The test is believed to afford indication of: (*a*) The stability of the respiratory centre, and indirectly of the nervous system generally. (*b*) The likelihood (when the time is short and an abnormal answer is given) of the subject suffering from oxygen-want at altitudes. (*c*) Resolution to "carry on" under conditions of stress.

(iii.) *Expiratory force.*—(Apparatus required: Mercury U tube.) The applicant or airman is asked to hold his cheeks with the thumb and forefinger of the left hand, and steadily to blow the mercury column of the standard U tube up as high as possible with the scale turned away. Several mouth-pieces should be kept in disinfectant and carefully cleaned for each subject. On no account must the applicant or airman be allowed to swing the mercury up violently, and in all cases the height of any initial swing is to be disregarded. The reason for holding the cheeks is that it has been found that in some cases the mercury may be forced up to abnormal heights by the action of the cheek muscles. The number of mm. Hg blown is recorded. The examinee is then asked to repeat the performance while looking at the column. The resolute subject may, under these conditions, considerably pass the effort which he did not see, in this way affording some indication of his mental make-up. On the other hand, a subject who is not trying may give very discrepant readings. With the manometer again turned away, he may, by encouragement, be made to surpass his previous efforts. But attempts made whilst looking at the manometer scale, will, if he is not really trying, fail to surpass previous efforts which he has seen.

The average for normal individuals is about 105 mm. Hg. When under 80 mm. Hg it suggests that the subject will probably be incapable of sustained effort in routine aerial work and should probably be rejected. The test, however, should be taken in conjunction with the results of the rest of the examination.

(iv.) *Fatigue test and pulse response.*—(Apparatus is given.) This test is performed as follows. The applicant is asked to empty the lungs, fill up, blow the mercury in the U tube to the height of 40 mm. and hold it there without breathing for as long as possible, the nose being clipped. The average time in the large number of cases tested is 50 seconds: below 40 seconds is unsatisfactory. An essential adjunct to this test is the behaviour of the pulse, which is counted every five seconds during the time that the mercury is sustained. Starting at the fifth second in the normal individual there is generally a steady slow rise in the rate of the pulse, or a fairly marked rise, which is sustained most of the time. For example, the pulse-rate may rise gradually from 72 to 96 or 108, according to the time the breath is held, or the pulse may rise almost at once from 72 to 96 or 108, and may be sustained there. A large rise in rate—e.g., from 72 to 132 or 144—is unsatisfactory. In cases of stress a characteristic response is for the pulse to jump up to a quick rate during the fifth to the tenth or fifteenth seconds, and then to fall away in rate to normal or even below normal.

Such a response is as follows: Normal at start, 84; 5th-10th second, 144—sometimes almost impalpable; falling away (say 20-25 seconds) to 72 or even 60. Such cardiometer instability is an adverse factor in aerial work and is an indication for rejection. Other points in the examination should, however, be taken into consideration. The test is to be recorded by first noting the number of seconds during which the mercury column is sustained, and then writing down the pulse-rate of 5 second intervals, e.g., 50—P.6677789888, the time taken to blow the mercury to 40 mm. being ignored.

This test affords information as to the stability of the medullary centres and of the power of resistance to fatigue.

(v.) *Flack's bag test and Dreyer's nitrogen test.*—Although these tests have proved themselves of great value detailed descriptions are not included here, partly because the time taken to apply them properly is considerable, and partly because they really require to be worked by trained physiologists. In the case of the Dreyer test, the apparatus is expensive and, at present, difficult to obtain. Should information be required as to the method of their use and results obtained, reference should be made to the publications of the Air Medical Investigations Subcommittee of the Medical Research Committee, Nos. 1, 2, and 5.

(*To be continued.*)

CHICAGO HEALTH REPORT.[*]

CHICAGO, which only had one white settler in 1804, and a population of 7,580 in 1843, is now a city of 2,596,681 souls, covering an area of 190 square miles, and increasing at the rate of 50,000 a year. Fifty-one per cent. of the population consists of males, and 97·9 per cent. are white men. As regards race, 62 per cent. were born in the United States, 14 per cent. in Germany and Austria, 6 per cent. in Russia, and 3 per cent. in Ireland. In 1918 the death-rate was 17·17 and the birth-rate 24·5 per 1000. But the latter figure is only a rough estimate, for birth registration has only been recently established, and in 1914 the reported births were 13,000 below the estimated. Accordingly, infantile death-rates are given in terms of total deaths, not of births. In 1918 14 per cent. of total deaths were under 1 year of age, which is 98 per 1000 of estimated births. The general death-rate, owing to the influenza epidemic, was the highest recorded since 1895, but infantile mortality was much less affected by the epidemic than the general mortality.

Functions of the Commissioner of Health.

The office of Commissioner of Health differs materially from that of the English medical officer of heath. The commissioner is the administrative head of the Department of Health, and is charged with the enforcement of all laws of the State, ordinances of the city of Chicago, and all rules and regulations of the Department of Health relating to the sanitary condition of the city. Infectious hospitals, public baths, laundries, and other health institutions are under him, and he is authorised to publish information concerning his work, the health of the community, and methods of preventing diseases. He thus combines, as regards public health, the functions of health committee, town clerk, and Asylums Board, with those of medical officer of health, and exercises more arbitrary power than any of these. He is responsible only to the mayor. Under him are an Assistant Commissioner and seven distinct bureaux, dealing respectively with (1) general administration, education, and publicity; (2) municipal laboratory; (3) medical inspection, including infectious disease, school hygiene, infant welfare, and day nurseries; (4) food inspection, with licensing of milk and food dealers; (5) birth and death registration and vital statistics; (6) sanitation, plumbing, housing, new buildings, public baths, and comfort stations; (7) isolation hospitals and ambulance service. Each bureau is under a bureau chief directly responsible to the Commissioner of Health. In addition to these bureaux which are directly under him, the Commissioner is the president or director of six correlated health agencies which work in coöperation with his department—viz., the Public Health Association, the Commission of Ventilation, the Tuberculosis Sanitarium, the Morals Commission, Board of Examiners of Plumbers, and Chicago School of Sanitary Instruction.

The Bureau of Vital Statistics controls funerals, undertakers, and cemeteries, and apparently depends more on this control than on the certificates of physicians for the reports of deaths. At any rate, statistics of deaths are said to have been complete since 1871.

For the control of infectious diseases the city is divided into 55 districts, with a health officer over each. He is required to inspect and quarantine all reported cases of diphtheria, scarlet fever, measles, mumps, and other infectious diseases. Cases of smallpox, typhoid fever, and infantile paralysis are at once removed to hospital and contacts kept under observation.

School Hygiene and Infant Welfare.

School hygiene and infant welfare are not separated as in this country, but are both under an assistant bureau chief, who supervises the medical inspection of school children, open-air schools, and "open-window rooms" at schools, the "field nursing service," the school dental service, and infant welfare service. There are 143 health officers, and about the same number of nurses, for the school work, or about one of each to every four schools. These school nurses during the two months' (July and August) school vacation help the Health Department nurses in health visiting. The work of the latter nurses appears to be similar to that of our health visitors. Each one has about a hundred infants under her care. The infants referred to her are those living in crowded districts, whose addresses are picked out from birth returns, and also bottle-fed infants and those confined by midwives. An average of 15 visits and re-visits is made in a day. There are four municipal infant consultation centres, and 22 under the Infant Welfare Society, but, says Dr. Robertson, 50 are needed. The object of both field and centre work is to keep well children well. Sick babies are only cared for in emergencies.

---

[*] Report and Hand-book of the Department of Health of the City of Chicago for the years 1911 to 1918 inclusive. By John Dill Robertson, M.D., Commissioner of Health. House of Severinghaus, 2141-49, Ogden Avenue. 1919. Pp. 1535. $5.

The Bureau of Food Inspection employs 77 food inspectors. All milk, cream, and ice cream sold in the city must be either "inspected" or "pasteurised." "Inspected" means complying with a fixed standard of purity, which is seldom reached, so that pasteurisation is the rule.

The Bureau of Sanitation deals with nuisances and insanitary conditions, and for this purpose employs 2 supervising and 35 sanitary inspectors. The bureau also exercises sanitary control over the construction and alteration of buildings, and all plans for habitable buildings must be submitted to it for approval *re* lighting, ventilation, plumbing, and draining. There are 4 ventilation and 17 plumbing inspectors, and plumbing work must be carried out by men who have been licensed by the plumbers' board of examiners.

Dr. Robertson's report deals in considerable detail with the work of all the different bureaux. It also contains four special reports on tuberculosis, venereal disease, the 1918 epidemic of influenza, and two outbreaks of acute anterior poliomyelitis (infantile paralysis) in 1916 and 1917. A foreword gives a general *résumé* of the most important problems of Chicago's health, and the report concludes with a historical chronicle and fairly complete index.

Water and Milk Problems

The health authority of Chicago, which now boasts of its being one of the healthiest cities of its class in the American continent, has had very great difficulties to contend with. The city was built on a plain slightly below the level of the lake of Michigan, and in order to make it possible to drain it by gravity the level of all buildings and streets had to be raised. This was done in 1855-6.

The problem of a pure water supply has not yet been satisfactorily solved. The water is drawn from Lake Michigan, which is continually fouled by the sewage of suburban towns, by bathers, and by careless steamboat officers. Five per cent. of non-treated water as supplied to houses would contain colon bacilli unless treated by chlorination; by carrying out the chlorine process "the colon content has been reduced to two-tenths of one per cent. in one cubic centimetre." The process is carried out at the street pumping stations, but the risk of the failure of an employee to fulfil his duty naturally causes anxiety to the Health Commissioner, and he recommends that the water should be not only treated with chlorine but also filtered. It is, indeed, curious that the rich and mighty city of Chicago should be no better off in the treatment of its water supply than an army in the field.

These observations recall the report of THE LANCET Special Sanitary Commission of Inquiry concerning the Water supply of Chicago, undertaken prior to the convention of a World's Fair, when thousands of visitors were expected to attend. The results were published in THE LANCET of April 8th, 1893. The pollution of the Chicago River was proved by numerous analyses made in THE LANCET Laboratory of samples of water obtained and forwarded to us by a responsible representative in the city. The water as supplied to the consumer hardly showed a clean bill, particularly in regard to suspended matter, and it is rather surprising to learn that after more than a quarter of a century has elapsed the problem of a pure water supply has not yet been satisfactorily solved. We suspect that one trouble at least arises out of the pollution caused by the drainage from the great stockyards of the city. This seemed to be the case with regard to the samples taken from the Chicago River, which served as a sewer, emptying directly into the lake. The work of analysis was under the control of Mr. (afterwards Sir) William Crookes, and later a series of articles appeared in our columns (the first of which was on Jan. 7th, 1905) from a Special Sanitary Commissioner of THE LANCET, who after visiting the St. Louis Exhibition took the opportunity while in the neighbouring State to investigate the Chicago stockyards and the condition of the abattoirs there. As his reports show, he was not favourably impressed with the sanitary regulations in force for the slaughter of the animals. His disclosures attracted considerable attention at the time and formed the text for a sensational novel.

Dr. Robertson appears to be satisfied with pasteurisation as the solution of the milk problem so long as this is efficient. By means of thorough inspection, rigid prosecution of offenders, and closing their establishments, he considers the attainment of efficient pasteurisation comparatively easy. Since "the practically perfect chlorination of its water and a complete pasteurisation of its milk we have not had a milk- or food-borne epidemic of any kind or description." The typhoid death-rate (0.01 in 1918) is the lowest in the large cities of the States.

Epidemic Diseases

Small-pox occasioned two deaths in 1917 and two in 1918. Vaccination is enforced through the schools, every child is examined once a year, and children found inefficiently vaccinated are referred to the family physician for vaccination or vaccinated by the school doctor. Small-pox had been absent for some years, but an outbreak occurred in 1917 and 1918, chiefly among coloured labourers imported from the South. Scarlet fever is a much more serious disease in Chicago than in London and caused more deaths in recent years than either measles or whooping-cough. Diphtheria is even more fatal, causing in 1917 and 1918 more than twice as many deaths as scarlet fever. The tuberculosis death-rate has fallen since 1907 from 1.7 to 1.4 per 1000, and the cancer death-rate, as on this side of the Atlantic, has risen persistently, and was 0.90 in 1918. The tuberculosis problem seems to be much the same in the States as in England, and is being met in Chicago in much the same way—by sanatoriums and open-air propaganda.

Tobacco and Opium Attacked

The health of a great city like Chicago continually presents new problems, and Dr. Robertson meets them undaunted as they arise. He has attacked nicotine by a successful request for the closing of "the dirty, filthy smoking compartments" on the railroads. He is now initiating a campaign against the abuse of opium, which he found was contained in 103,000 out of 400,000 prescriptions given in one month for influenza and pneumonia. President Wilson was asked that a stipulation should be made in the Peace Treaty for stopping the growth and importation of opium. Such an energetic reformer is bound to meet with opposition, and while congratulating Dr. Robertson on the fact that "a large majority of the aldermen have taken an active interest in the Department of Health," one would like to know more of the "very few instances in which 'they made improper requests of the Commissioner.'"

Conclusion

The report is illustrated by a large number of the pictorial health posters in which the American excels. The vital statistics, too, are mainly presented in the form of pictorial and block charts, which are a little embarrassing for those searching for exact figures. But it is impossible in a short notice to deal with all the noteworthy features of this valuable report. Those who wish for interesting information on placarding infected houses, detailed rules of quarantine, epidemics of influenza and infantile paralysis, a departmental "hearing board" for dealing with nuisance offences before prosecution, a system of promotion in the public health service by an elaborate scale of marks for ability, activity, reliability, &c., must be referred to the report itself, and we think they will not regret making fuller acquaintance with it. The total cost of the Chicago Department of Health in 1918 was $1,151,000, of which $430,000 were for the treatment and prevention of communicable diseases, and $240,000 for conservation of child-life.

Great Britain led the way in public health administration, but America has followed hard after us, and unless we imitate her courage in dealing with vested interests and in subordinating private privileges to public welfare, we shall soon have to take the second place.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Ireland and the Medical Research Council.

THE fact that, in the constitution of the new Medical Research Council, Ireland has been ignored is giving rise to comment in medical circles in this country. Ireland differs more in its social and health conditions from Great Britain than does Scotland from England, yet Scotland is, as is quite proper, represented on the Council. As each part of the kingdom contributes proportionately to the expenses of the Council, each should share in the advantages likely to accrue from its work. With the present constitution of the Council it is almost inevitable that problems of Irish importance will be overlooked. It is all the more important that there should be some one on the Council with special knowledge of Irish conditions in view of the fact that, whereas both England and Scotland have Ministries of Health which can press their interests, Ireland, although nominally possessing a Minister of Health, has as yet no Ministry. How actively the late Minister of Health for Ireland looked after her interests can be judged from his consenting to the constitution of the Research Council, without even, I understand, thinking it necessary to take the advice of the Irish Public Health Council, whose statutory duty it is to advise him in matters concerning the health of the country.

Pathology and Research in Belfast.

It is to be hoped that an arrangement may be made so as—following the example of Liverpool—to bring closer together the city of Belfast, in its public health aspects, and the University. This can be easily done by the latter supplying the Public Health Committee of the Belfast City Council with separate rooms in its pathological buildings, leaving the corporation to appoint its own officials, and making the professor of pathology and bacteriology the head and superintendent of the combined department. A joint meeting of the representatives of the Public Health Committee and of the University was held last week, and a deputation was appointed to place the above views before the City Council of Belfast.

Charter Dinner at the Royal College of Surgeons in Ireland.

On April 17th the President and Fellows of the Royal College of Surgeons in Ireland held their first Charter Day since 1914, the President, Mr. J. B. Story, in the chair. There was a large attendance of Fellows and guests, the latter including the Lord Chancellor of Ireland, the Provost of Trinity College, and Sir Archibald Geikie.

AT a meeting of the Torquay and District Anti-Vivisection Society, held recently, it was reported that little had been done during the past year owing largely to "lack of funds, interest, and enthusiasm, a kind of apathy having fallen on the branch since the war."

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Yellow Fever in India.

THE Yellow Fever Committee appointed by the Government of India has arrived at unanimous conclusions regarding the measures which, in its opinion, should be adopted in order to keep the Peninsula free from infection by the disease. The stegomyia mosquito abounds in India, but it is easier to reduce the number of this species than it is to effect a reduction of the anopheles which transmits malaria, since the stegomyia generally breeds in and about houses, especially in vessels used for the storage of water. Lieutenant-Colonel S. P. James, who was deputed to the Government of India to report on the whole question of yellow fever prevention, urged that the provision of a constant high-pressure supply of water in the various sea-ports, which would render the storage of water unnecessary, should be the first step taken to reduce the stegomyia. In his opinion, if the policy of reducing stegomyia in the ports proved successful, it would ensure permanent safety against yellow fever. Other questions involved are the establishment of quarantine stations at the ports, and the securing of information from the countries in which yellow fever is endemic regarding the movement of the infection to the East. Colonel James held that the only satisfactory method of obtaining this information was to station permanently in the endemic area a medical officer who would be constantly in touch with the consular and quarantine officers of the United States and other countries. This officer in practice would be attached to the British Consulate at Panama, and it would be his duty to report promptly any new danger threatening the East. A second officer might be posted at Hong-Kong, and a third at Singapore. The American Government have for years followed the practice of attaching officers of their public health service to their consulates in the ports of foreign countries, and it has been apparently attended by very satisfactory results.

Small-pox Preventive Measures in Calcutta.

The health officer, Calcutta, in a note on the preventive measures to be used in the present epidemic in Calcutta, says the epidemics tend to occur every four or five years in the town. The present outbreak is as severe as the outbreak of 1915, if not worse. In 1915 there were 10,000 cases and 2500 deaths. If the present epidemic assumes similar proportions 50 to 100 contacts will have to be registered, for as only a small percentage of cases are treated in hospital, under the circumstances it will be well-nigh impossible to avoid exposure to infection. Accordingly a vigorous vaccination campaign has been started on a well-organised basis. Special arrangements are being made for the vaccination of University students and school children. The health officer refers to the provisions made for extra hospital accommodation and convalescent homes, and states that a large supply of medicated oil has been prepared and distributed free of charge.

Leprosy in Cochin.

The Cochin local government has decided to close the leper colony in Venduruthy Island, Malabar, established 300 years ago, and to transfer the inmates to Calicut Mission Leper Hospital.

The All-India Medical Conference.

The presidential address at the Third All-India Medical Conference was given by Dr. M. N. Ohdedar, who entered the profession from the Lahore Medical College in 1879. The dominant note of the address was struck from the beginning, when, in an allusion to the Committee on Reorganisation of the Medical Services in India, that body was called a "packed committee," on which the views of the provincial medical services and private practitioners were not represented, disappointment being expressed at the prospect of a continued preponderance of Indian Medical Service officers in civil medical appointments. It is well that British readers should understand the native views on a very difficult point, and they were stated fully in the address. While special credit is allowed to the I.M.S. officers for the ability with which they have conducted the Medical Colleges in the country, it is claimed that "a large number of Indians have so well profited by the training imparted by these professors, and by their natural aptitude and desire to rise high in the profession, that they are in no way inferior to the average general practitioners in any country, while some will compare favourably with the best general practitioners anywhere." Exception is taken to the suggestion that medical degrees and qualifications in India do not in all cases represent the result of a complete medical education, such statements being logically regarded as "a strange commentary on the capabilities of the Indian Medical Service professors, by whom the Colleges in India have been wholly manned in the past, and are, to a very large extent, in the present."

With regard to the large number of Indian medical men engaged as temporary commissioned officers during the war, the President considered it matter for regret that only a small percentage are likely to be made permanent in the department; so long as officers of the R.A.M.C. are drafted into civil employ he urges that "the Association should make a vigorous representation, remembering that the child that does not cry gets very little attention." This remark is very apposite, but it can be read in a way which its author did not intend. Dr. Ohdedar went on to say: "It cannot be denied that the Medical Department in India is the only department in which the interests of the officers clash with those of their assistants and of the alumni of the medical colleges generally in this country; and it is owing to this stumbling block that the claims of Indian medical men for responsible posts have not yet been freely recognised." The thing that is of greatest importance is the efficiency of the Medical Service—that is, the care of the sick and the preservation of the health of the whole population, civil and military. To ensure this a contented body of officers of all grades is necessary, and, of course, every effort should be made to bring this about. Dr. Ohdedar frankly recognises "that the very high appointments in the Medical Department should for years to come be reserved for the officers of the Indian Medical Service, be they European or Indian," and his opinion is that "a great number of the civil surgeoncies and a good number of appointments in the sanitary and chemical departments might be well given to qualified natural-born Indian subjects of His Majesty with advantage both to the country and the finances of the Government of India." But when he goes on to say that "it is only when a man is not able to earn even as much as a panel doctor earns in his own country that he, nolens volens, accepts service in a foreign country," and to comment unfavourably on the scientific ability of the I.M.S. officers, he is talking nonsense, and nonsense which spoils some of his own best arguments. With regard to the selection to professorial appointments, everyone will agree that the very best men available should be appointed, whether European or Indian; also that they should not be liable to frequent transfers, and that they should be well paid. Dr. Ohdedar considers that at least half the professorial appointments should go to qualified Indians, paid adequately, and debarred from general private practice. He refers to the important researches that have been carried out by many members of the Indian medical profession in various parts of the country, and to the laborious "spade-work" of the "licensed medical practitioners" and "sub-assistant surgeons," which designations, he considers, should be abolished. But he is critical now and again of his own countrymen, as when he regrets that "many men in Government service should not have the ambition to distinguish themselves in surgical work; and that through fear of losing the insufficient pay they get, they should allow the I.M.S. officers without any protest to monopolise the whole of the important surgical work."

In conclusion, Dr. Ohdedar advocates the formation of an association in India, on the same lines as the British Medical Association, including medical men of all classes, that would carry on continuous propaganda work in a constitutional manner, "move the authorities to listen to the grievances of the locally trained men, whether in the service or out of it, and minimise the baneful influence that the British Medical Association has in the shaping of the medical policy of the Government of India."

Home for Indian Children.

Recently the foundation-stone was laid of the home for children at Matunga, near Bombay, to be built by the Society for the Protection of Children in Western India at a cost of Rs. 2,72,000. The Bombay corporation recently voted an annual recurring grant of Rs. 2500 and a building grant of Rs. 15,000 towards this institution.

Retention of Rank in the I.M.S.

An Army Instruction announces that it has been decided that the rules regarding the retention of rank contained in Army Order No. 376 of 1918 shall apply in the case of officers of the Indian Medical Service (whether holding temporary or permanent commissions) who have served satisfactorily during the war. This retention of rank will take the place of honorary rank granted hitherto.

ADVERTISEMENTS IN THE MEDICAL PRESS.

AT a meeting of the Worcestershire County Council on April 24th the Chairman (Mr. Willis Bund) said that the Council would recollect that in connexion with the medical service scheme for the county they authorised advertisements for ten doctors at salaries of £450 each. They obtained two officers, and they then proposed to repeat the advertisement, but when they sent it to the *British Medical Journal* and *The Lancet* they received letters stating that advertisements could not be accepted which offered a less salary than £500 per annum for such posts. The chairman said that he also had a letter from the Ministry of Health stating that tuberculosis officers should have special qualifications and experience, and they doubted whether the salary offered (£450) would be sufficient. He said that he objected to this sort of pressure being put upon local authorities. (Hear, hear.) A matter like this was nearly more than they could bear. When they had got two gentlemen for £450, who, he thought, were very suitable for the posts, then they got these letters trying to prevent them getting any more. He did not quite know what to do in the matter. He felt very averse to allowing the medical press to dictate to them as to what salaries they should give. (Hear, hear.)

Dr. Dixey said that not only the Ministry of Health suggested that they would be unlikely to get officers of the calibre they desired at the salary they offered, but Dr. Fosbroke (the medical officer of health), in his report on the scheme, said that he was by no means certain that they would get thoroughly competent officers at £450. He hardly thought that the members of the Council would think that a salary of £500 was an extravagant sum, having regard to the cost of living, to be paid for a medical officer to do the amount of work that he had to do under the scheme. He would have to do the ordinary work of medical inspection of school children, and if they were going to get good results for the large amount of money they were going to spend on the scheme the officer must have some good knowledge and be a man who would be likely to do good work. The only alternative was to tell the Ministry of Health that they would not carry out the scheme. He proposed that the committee be authorised to advertise for eight assistant medical officers at a commencing salary of £500, rising to £600 per annum by annual instalments of £25; that the two medical officers appointed be placed on the same footing; and that the two senior assistants shall have special advisory functions, and shall receive a salary of £600 per annum, rising to £700 by annual instalments of £25. Dr. Dixey said that they had advertised for a dentist at a salary of £400. They had four applications. Three of them were not eligible, and one the committee thought would do and they agreed to appoint him, but he had sent a telegram that day stating that he declined the post. The speaker suggested that they should advertise for a dentist at a salary of £450. He hoped that the Council, who passed the full scheme and knew the necessity for it, would agree to the proposals. The net increase would be £650 a year, and half of that sum would be paid by the Board of Education, so that the total cost to the county would be £330.—Dr. F. W. J. Coaker seconded.

Mr. Millward said it was to him extraordinary that papers should take the position stated by the chairman. He was not satisfied that medical officers could not be obtained, and he moved that they advertise in other than the medical press—in some of the London daily papers.

The Vice-Chairman (Colonel Wheeler) seconded. He did not think that they should sit down under the treatment accorded to them by the medical press. He was not satisfied that they could not obtain the officers. After they had tried it would be time enough for them to consider whether they would give more or not. He could not help thinking that there were many young medical officers who would be glad to start at the figure of £450.

Dr. Dixey said that they advertised in the daily press at a crisis like that some years ago, and they got no answer.

Mr. H. C. Gardner: I do not think that is so.

The Chairman: I think we got some answers, though we did not appoint anyone.

Mr. G. E. Wilson said that this was not a new policy on the part of the medical press. The Council advertised in vain for medical officers for the asylum some years ago at a figure that was not considered a reasonable figure.

Mr. C. Dalley said that they would be unwise to play with this matter. They wanted medical men, and they would have to pay the price demanded. £500 a year for a trained medical man was not an extravagant sum.

Dr. L. C. S. Broughton asked the Council what sort of a medical man they hoped to get for £450 a year? There was a very serious shortage of doctors, which would be felt more in three or four years' time than to-day. The medical papers were simply standing out for a respectable salary for a highly trained medical officer. He was rather amused to hear Mr. Millward say that he thought that they could get doctors by advertising elsewhere than in the medical papers. He hoped that they would advertise and that they would get a doctor, and he hoped that they would be glad of him when they got him.

The amendment to advertise in the daily press was carried by 34 votes to 23.

URBAN VITAL STATISTICS.

(Week ended April 24th, 1920.)

English and Welsh Towns.—In the 96 English and Welsh towns, with an aggregate civil population estimated at nearly 18 million persons, the annual rate of mortality, which had declined from 18·7 to 15·8 in the four preceding weeks, further fell to 14·5 per 1000. In London, with a population of nearly 4½ million persons, the annual death-rate was 14·2, or 1·9 per 1000 below that recorded in the previous week, while among the remaining towns the rates ranged from 3·5 in Wimbledon, 5·0 in Ealing, and 7·1 in Wallasey, to 23·3 in Newport (Mon.), 24·4 in Blackburn, and 26·1 in Halifax. The principal epidemic diseases caused 354 deaths, which corresponded to an annual rate of 1·0 per 1000, and comprised 145 from measles, 85 from whooping-cough, 55 from infantile diarrhœa, 42 from diphtheria, 18 from scarlet fever, 7 from enteric fever, and 2 from small-pox. Measles caused a death-rate of 2·1 Stockport, 2·4 in Brighton, 2·9 in Rhondda, 4·2 in Wigan, and 4·8 in Newport (Mon.); scarlet fever of 1·1 in Stoke-on-Trent; and whooping-cough of 4·1 in Darlington. One death from small-pox belonged to Liverpool, while the second (a Norwegian seaman) occurred at the Metropolitan Asylums Board's Shelter in Bermondsey. The deaths from influenza, which had declined from 392 to 306 in the four preceding weeks, further fell to 259, and included 59 in London, 11 each in Birmingham and Liverpool, 10 in Sheffield, and 9 in Blackburn. There were 1965 cases of diphtheria, 1845 of scarlet fever, and 23 of small-pox under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, against 1958, 1904, and 24 respectively at the end of the previous week. The causes of 28 of the 4967 deaths in the 96 towns were uncertified, of which 5 were registered in Birmingham.

Scotch Towns.—In the 16 largest Scotch towns, with an aggregate population estimated at nearly 2⅓ million persons, the annual rate of mortality, which had been 17·2, 17·3, and 18·9 in the three preceding weeks, further rose to 19·2 per 1000. The 410 deaths in Glasgow corresponded to an annual rate of 19·2 per 1000, and included 31 from influenza, 20 from measles, 7 from infantile diarrhœa, 4 from whooping-cough, 3 each from small-pox and diphtheria, and 1 each from enteric fever and scarlet fever. The 94 deaths in Edinburgh were equal to a rate of 14·4 per 1000, and included 4 from influenza and 2 each from measles and diphtheria.

Irish Towns.—The 227 deaths in Dublin corresponded to an annual rate of 28·5, or 3·0 per 1000 below that recorded in the previous week, and included 9 each from measles and whooping-cough, 5 from influenza, and 2 from infantile diarrhœa. The 219 deaths in Belfast were equal to a rate of 27·6 per 1000, and included 13 from influenza, 5 from infantile diarrhœa, and 1 from measles.

THE RELATION OF GENERAL MEDICINE TO OPHTHALMOLOGY.

To the Editor of THE LANCET.

SIR,—The Ophthalmological Society is discussing this week the relation of diseases of the eye to certain general morbid conditions. I should like to recall the meeting of the Ophthalmological Section of the Royal Society of Medicine, held on Dec. 3rd last, when a discussion was introduced by Dr. Rayner D. Batten[1] on the relation of general medicine to ophthalmology. His suggestion, which received a certain amount of support, was that there should be ophthalmic physicians as well as ophthalmic surgeons. He pointed out what advantages there would be to the ophthalmic surgeon from such an arrangement.

I do not think it would help the ophthalmic surgeon in the least. So far as he is concerned there is no use for the ophthalmic physician; any coöperation between the two would be, as it always has been, of greater assistance to medicine than to ophthalmology. Some 30 years ago ophthalmologists began to have an inkling that defects of vision were responsible for general conditions of health, and, on the other hand, that general conditions had a considerable share in causing eye trouble; I do not think that physicians and general practitioners at that time were alive to the connexion.

One of the first conclusions arrived at by ophthalmologists was the rôle played by anomalies of refraction in the causation of headache, and in or about 1888 two papers were written on ocular headache, one by Mr. Brudenell Carter, the other by myself, and possibly some by other ophthalmologists. Mr. Carter said that many children in schools were dull and listless and complained of their heads, and there was difficulty in teaching them; they were thought to be stupid. Mr. Carter's comment was that "the stupidity was entirely on the part of the teachers."

In my own paper I reported some well-marked cases of eye headaches with remarks upon them. These cases are only examples of thousands which come under the treatment of the ophthalmic surgeon, and of which, till a comparatively short time ago, the rest of the medical profession had no knowledge; where, then, do the physicians come in? Physicians and general practitioners knew nothing of ocular headache until its existence was pointed out by the ophthalmic surgeons. I may say that when the profession did become alive to the fact that eye trouble was a common cause of headache (that was after the publication of papers calling attention to it in 1888), the number of cases of headache treated by ophthalmic surgeons increased very considerably. To prove this I give the number of cases that consulted me for headaches at different periods. Between October, 1887, and October, 1888, among 512 cases there were 28 who complained of headache. This was about the commencement of the period of enlightenment. Before this date, between July, 1885, and September, 1886, among 493 there were 10 cases of headache. This was before the ophthalmic surgeons knew much about ocular headaches. Later, between April, 1892, and May, 1893, among 506 cases there were 44. By this time eye trouble was under suspicion in cases of headache. Between June, 1900, and April, 1901, among 506 cases there were 75. The ocular cause of headache had become known not only in the profession but by the public generally. Had the profession only appreciated this cause 30 years ago what an enormous amount of inconvenience and even suffering might have been prevented.

---

[1] THE LANCET, 1919, ii., 962.

There is another class of case of which a number, after having been treated by medical men for long periods, eventually seek the advice of an ophthalmic surgeon. These are cases of what may be called sore eyes. There may be slight conjunctivitis, lacrymation, redness and slight swelling of the edges of the lids, especially in the morning after sleep, and a sense of general discomfort. Lotions of all sorts have been used without any result. The ophthalmic surgeon almost invariably finds some slight error of refraction, generally a low degree of astigmatism. He orders suitable glasses and tells the patient to continue any one of the lotions he has already been using; recovery very soon takes place. There are quite a number of cases of Bright's disease which have never been discovered until the patient's sight has become affected and he consults an ophthalmic surgeon, either on his own account or by the advice of his medical attendant. The ophthalmic surgeon examines him with the ophthalmoscope and finds albuminuric retinitis, which means that the disease has been going on, perhaps for years, undetected and untreated; moreover, albuminuric retinitis is a late symptom and its occurrence is a sign that the patient is approaching his end. This is another instance of assistance given to medicine by ophthalmology.

Another class of cases in which the cause of eye trouble is often discovered when the patient consults an ophthalmic surgeon is a condition of general sepsis; the eye trouble need not necessarily be septic, though cases of septic inflammation of the eye do occur, but there is more often some interference with sight and want of power to use the eye without any very apparent cause. The ophthalmic surgeon finds weakness of accommodation and perhaps a slight error of refraction of which the patient was unaware whilst he was in good health; but having become weakened by septic infection from some self-contained cesspool he is troubled by what had previously been no inconvenience. A little inquiry will generally discover the cause, but whatever the cause may be it is the ophthalmologist who makes the discovery, not the practitioner of medicine, and he advises the patient to consult the dentist, nose and throat specialist, or general surgeon, with the result that the cesspool is drained or removed and the patient recovers. Other sources of infection allied to sepsis are gonorrhœal or syphilitic virus, which every medical man knows are the main causes of iritis and many other affections of the eye; but I do not think that the profession at large is aware that gonorrhœal infection is by far the most common cause of iritis, and responsible for all the most severe and troublesome cases. Nor do I think that general medicine will enlighten them on the subject. Iritis has from time to time been divided into many varieties, but I think (and fancy that a good many ophthalmologists are of the same opinion) that at least 95 per cent. of cases of iritis are gonorrhœal or syphilitic, and there are some mixtures of the two.

Many nerve cases in their early stages are discovered by ophthalmologists. The patients may have consulted a medical man only because they had noticed something wrong with their eyes, and may then have been advised to go to an ophthalmic surgeon. Here again ophthalmology comes to the aid of medicine. The ophthalmic surgeon discovers possibly something serious, such as double neuro-retinitis or wasting of the optic nerves. But not unfrequently it is something very slight of which little or no notice has been taken by the doctor, such as slight diplopia. It may mean nothing, but, on the other hand, it may be the first symptom of serious nerve trouble.

I could give many instances in which medicine has been helped by ophthalmology, but think I have said enough. There is no place for the ophthalmic physician, and what the ophthalmologist does not know of medicine as it concerns his specialty no one else is likely to teach him.

I am, Sirs, yours faithfully,
CHARLES HIGGENS, F.R.C.S.

Brook-street, W., April 5th, 1920.

AN UNUSUAL FOREIGN BODY IN THE EAR.

To the Editor of THE LANCET.

SIR,—On April 4th a constable came to me at the City of London Police Hospital complaining of deafness and occasional pain in his left ear. On examination I saw a black glistening plug which I took to be impacted cerumen; the right ear was clear. I directed him to put almond oil into the ear and come up for syringing in two or three days. He came on the 6th and a nurse syringed the ear without result. He saw me at midday and I again syringed the ear and, after some rather forceful syringing, the plug moved outwards and I was able to help it out with the nozzle of the syringe, when it proved to be a beetle. When I announced this result the constable informed me that about 18 months previously he was in France, and sleeping on the ground under canvas. He awoke one morning and felt a tickling sensation in his left ear. He pushed his finger in and felt some squashing of an insect and the thing seemed to crawl right in; some blood (presumably the beetle's) came out of his ear. He went to the medical orderly in agony, and he put something into the ear and told him he must have had a boil or something of the sort, and what he took to be an insect crawling must have been due to the blood trickling when it burst. The orderly syringed the ear twice; and on some later occasion he saw another orderly, who syringed it again, but he never saw a doctor till he came to me. After removal of the insect the ear was clear, and he said he could hear properly again, and beyond some local redness about the handle of the malleus I detected nothing abnormal.

The beetle was singularly well preserved, legs, antennæ, and case being complete. I took it to Professor A. Keith at the Royal College of Surgeons, and have received the following from him: "We had to send your beetle to the British Museum to be identified. His name is on annexed slip with the identification He is a native of France. His length is 19 mm. and he is 7 mm. wide. We are keen on keeping the beetle and showing it in our Foreign Body series." On the slip was: "*Carabus convexus*. Fab.—Carabidæ—predaceous beetles—feeding on insects, larvæ, &c., and on worms. *C. convexus* does not occur in Britain.—C. Gahan, Keeper of Entomology, B.M."

I am, Sir, yours faithfully,
A. P. GIBBONS, M.B. Lond., &c.,
April 26th, 1920. Surgeon to the City of London Police.

LICE AS A CAUSE OF RINGWORM.

To the Editor of THE LANCET.

SIR,—About the year 1909 I began to suspect some causal relationship between lice and ringworm of the head. At that time I was examining some hundreds of cases of ringworm per week, and the more I saw of the disease the more convinced I became that my suspicions were well founded. In the majority of the cases examined I found either lice or the eggs of lice present. In the minority of the cases, where the actual presence of lice or nits could not be demonstrated, it was generally admitted by the parents that their children had recently suffered from lice or nits. The number of cases where no such history could be obtained was so small as to be almost negligible.

The fact that ringworm is most common in the elementary schools, much less frequent in secondary schools, and of fairly rare occurrence amongst children in public or high schools in the country, is, I think, incontrovertible. Why, then, should the disease attack in this special order of frequency, and what causal factor is there which corresponds? The presence of lice and their eggs follow exactly the same distribution—that is, they are found rarely, and then only sporadically, amongst public and high school children, to some extent in the secondary schools, and quite commonly in the elementary schools. Considering the presence of two conditions identical in distribution, I proceeded to make cultures from the hairs infected by ringworm fungus, from lice found on ringworm heads, and from lice on heads which were not infected by ringworm. The results were such as to confirm my earlier suspicion, for from ringworm hair and lice from infected heads I grew ringworm (Sabouraud's media), but not from the lice of non-infected heads.

These experiments extended over a prolonged period of time and were considerable in number. From the results obtained I came to the conclusion that infected lice provide one means for the transference of ringworm from one child to another.

I do not suggest that the louse acts as a host in the usual acceptation of the term, or that there is any cycle of change, but I do suggest that the fungus is carried on the body or extremities of the louse, which is thus merely a direct carrier.

I do not wish to exclude direct infection from one child to another; this probably does occur, but in quite a small percentage of cases. Whilst I was making these researches the war broke out, and unfortunately my notes and data have been lost or destroyed. My object, however, in bringing the meagre facts to the notice of the profession is that others who have laboratories and the necessary time may carry these investigations further. My experience of school medical work suggests that the incidence of ringworm will lessen as the warfare on lice continues to be rigorously carried on.

I am, Sir, yours faithfully,
ALGERNON E. L. WEAR,
April 26th, 1920. School Medical Officer, Leeds.

THE DIAGNOSIS OF MALARIA.

To the Editor of THE LANCET.

SIR,—I should like to make a few remarks in connexion with Colonel Mathew D. O'Connell's letter on the Diagnosis of Malaria, which appeared in your issue of Feb. 28th. I regret that my absence from England has precluded me from writing this note earlier.

So far as the army in India is concerned, it is only after many years of continuous effort that we have established microscopical examination of the blood as a routine measure in all military hospitals in cases of pyrexia, both in cantonments and in the field. It is impossible to exaggerate the enormous advantage to the health of the troops that has resulted from this practice. The statistics given in the Reports of the Sanitary Commissioner with the Government of India indicate the extent to which malaria has undergone reduction in the army in India during the last 20 years, and this is due, at least partly, to the more accurate and definite diagnosis of malaria by microscopical examination of the blood.

From experience in the field as an administrative medical officer I know that carrying out blood examinations properly in all field ambulances and general hospitals is an exceedingly difficult undertaking, but every effort has to be made to see that it is done. The war has taught us much, and it is inconceivable that at the present day our Home or Indian Government would send an army into a malarious country without an efficient staff of medical officers and subordinates capable of carrying out blood examinations and the means of doing so. Blood examinations by the microscope are of special value in diagnosis in India, where we meet with several varieties of fever; during these examinations we at times unexpectedly come across parasites other than those of malaria. For example, in the recent Afghan campaign, in one Indian general hospital three cases of relapsing fever were so discovered, and in the epidemic of relapsing fever in Meerut in 1917 several cases diagnosed as malaria initially were found to be relapsing fever, and some years ago I remember Lieutenant-Colonel C. Dawes, I.M.S., showing me a case in Lansdowne which was thought to be malaria, but in which *Spirochæta carteri* was found in the blood. Dr. Philip Manson-Bahr refers to similar cases in his letter on the same subject in your issue of March 13th. In passing I would take the liberty of endorsing all that is stated by that talented writer in the letter referred to.

Our present methods of microscopical examination of the blood undoubtedly fail to diagnose malarial infection in a certain proportion of cases in which it is present, but I hold that this demonstrates the necessity of improving our methods rather than doing away with them. We are in India in possession of abundant evidence pointing to the necessity for more continuous examination of the blood for parasites in fevers of unknown origin in malarious stations and in the field. Let me quote one group of facts in support of this statement. In the Burma Division up to August, 1911, a large percentage of "fever" cases were returned as "pyrexia of uncertain origin," the practice being to rely upon a single examination of a stained blood smear for malarial parasites. From that month onwards daily microscopical examinations of the blood in all cases of undiagnosed pyrexia were carried out, quinine being withheld until parasites were found in the peripheral blood. Over 9000 slides were examined in connexion with 715 infections. In one case parasites were not found until the eighth day, in 2 on the seventh day, in 5 on the sixth day and 4 on the fifth day, in 11 on the fourth day and 43 on the third day, in 127 on the second day, the remainder on the first day; in other words, in a high percentage of proved malarial infections parasites were stated to be absent during the first paroxysms. In two Indian battalions quartered in Mandalay, which used to be a very malarious cantonment, six months after the adoption of this change the place of practically all the cases of fever of uncertain origin was taken by malaria in the returns. A similar series of facts was recorded in the 6th (Poona) Division in the last quarter of 1913, although these latter observations were not pushed to such a completely logical conclusion as those of the Burma Division.

The records of our military hospitals in India show that frequently malarial parasites are not found in the peripheral blood during malarial paroxysms. The chief reason given for the failure to find parasites is that the patients are at the time taking quinine either prophylactically or curatively. Personally, I consider that when malarial parasites are in sufficient numbers in the blood to give rise to malarial paroxysms they can in the vast majority of cases be found in the peripheral blood, especially if the thick-film method be employed and quinine be withheld temporarily.

The practice of giving quinine in cases where malarial parasites have been definitely shown by repeated microscopical examination of the blood to be absent is, I believe, therapeutically unsound. One great disadvantage of giving quinine in cases of doubtful fever is that after its use the diagnosis of the case may never be cleared up. When all evidence shows that there are no malarial parasites in the peripheral blood, abstaining from giving quinine can do no serious harm to the patient in the vast majority of cases. It may sometimes happen that the disuse of quinine in such cases for some days enables the diagnosis to be settled by parasites appearing in the surface blood. Although we know that quinine is a specific in a large proportion of cases of malarial infection, the fact that it brings about the disappearance of pyrexial phenomena does not prove that the fever is malarial. Quinine is an antipyretic apart from its plasmocidal properties. It is considered that as a routine practice no case of fever should get quinine until malarial parasites or other changes in the blood indicate that the case is one of malarial fever or that the clinical manifestations are definitely those of malarial paroxysms.

It has never come to my knowledge that abstaining from giving quinine in doubtful cases of fever while the diagnosis was being cleared up has been injurious to the patient. Nevertheless, we cannot alienate the responsibility of the officer who is treating the case, and he must decide for himself whether quinine is to be given in any particular doubtful case or not.

In the Burma Division in all cases of P.U.O. a blood examination for malarial parasites consisted of the following carried out on three consecutive days: (*a*) Examination of two stained smears; (*b*) examination of two fresh films; (*c*) examination of a stained thick film; (*d*) examination for pigmented leucocytes; (*e*) a large mononuclear count. The first two will usually be sufficient, and where negative for three consecutive days malarial infection might be eliminated. A positive result, of course, removes the necessity for further microscopical blood examinations as regards diagnosis. It was directed that quinine should be withheld, except in cases where the clinical manifestations were obviously of a malarial nature and serious in character.

It is admitted that the course adopted was rather a large undertaking and involved much antecedent preparation. Assistant surgeons and sub assistant surgeons were sent for courses of special malarial training, more microscopes were obtained, and one or more assistant surgeons or sub assistant surgeons in every hospital were taught to examine the blood systematically. The results were beyond all expectations. The P.U.O.'s, which previously ranged from 60 to 80 per cent of cases admitted with clinical manifestations of pyrexia, were reduced in two stations out of ten to nil, and in no station exceeded 10 per cent. These observations were closely watched and checked by myself and my D.A.D.M.S. (Sanitary), Lieutenant Colonel Tilbury Brown, D.S.O., R.A.M.C.

It is of the greatest importance to the individual patient to know whether he is or is not suffering from malarial infection. If he is he must take a curative course of quinine to eradicate the infection. Those of us who have been obliged to go through this regime know that it is no trifling undertaking, and it is downright cruelty to subject anyone to it unnecessarily—that is, without a positive diagnosis.

A valuable and important practical point has been brought out by Colonel O'Connell's letter that more scientific work should be done with the view to perfecting our means of finding malarial parasites in cases of malarial infection in which our present methods are insufficient. The thick film of Ronald Ross is a great help, but fails in a certain proportion of cases. One expected something in this direction to be developed from the Bass John method of centrifuging the blood in malaria, up to date, anyhow in India, it has been of scientific interest only, whilst it is quite impracticable in the field. I should be reluctant to believe that with so many highly trained experts in malaria in the British Empire some simple method could not be devised of tiding us over the difficulties connected with the small proportion of malarial cases in which at present the diagnosis cannot be definitely determined microscopically. I am, Sir, yours faithfully,

P. HEHIR,
Major General I.M.S. (ret.)

Salerno, Italy, April 10th 1920

AN ANGLO-AMERICAN LIBRARY FOR CENTRAL EUROPE.

To the Editor of THE LANCET.

SIR,—In your issue of April 17th, you published the gist of a document issued under the auspices of the British and American members of the Society of Friends, and having as trustees Professor Gilbert Murray, Mr. Arnold S. Rowntree, and the Rev. Canon William Temple, setting forth the need of intellectual workers and teachers in the universities of Central Europe for English and American books on philosophy, science, and literature. In order to meet this need the promoters of the scheme propose to establish "in Central Europe under British American auspices, one or more libraries of recent English books indispensable to university teachers." Such books at present cannot be obtained in Central Europe except at exorbitant prices, and, as a consequence, scholars in these countries find themselves cut off from access to books printed in English since 1914, which means that intellectual workers are deprived of indispensable tools. There is, we are reminded, "a hunger of the mind" as well as of the body.

At first sight it would seem more fitting that the British and American nations should devote their energies to healing the wounds and binding up the sores of their allies France and Belgium, for both these countries are in part or in whole blasted with war, and the damage to the great library of Louvain University caused by the apostles of Kultur is in great part irreparable. But on second thoughts it becomes plain that they that are whole do not need a physician, but they that are sick. France and Belgium are nations who have within themselves the essentials of civilisation and are in touch with the thoughts and ideals of both Western Europe and the United States, whereas the nations of Central Europe not alone before the war, but during its course, and even now that it is over showed and show themselves either ignorant of or oblivious to the ideals of civilised nations. If the provision of British and American books can drive into the hearts of German professors such elements of morals as that it is well for a country to keep its plighted word, that the wanton destruction of a library or of a great monument of human intellect such as the cathedrals of Malines or Rheims is a sin against the light, then we may hope that those whom they teach who are suffering from "a hunger of the mind and soul as well as of the body," will begin to realise the meaning of the words, "Blessed are they that hunger and thirst after righteousness for they shall be filled."

The promoters of the scheme say in their circular, "The reconciliation amongst the peoples can only come through the cultivation of mind and spirit, and it is clear that the great teachers of the world, by the free interchange of ideas, must be the leaders in such an endeavour." We may be allowed to doubt whether there are any great teachers of the world to day, great, that is, in the sense in which Newton, Pascal, Laplace, Kant, William Herschell, Faraday, Ludwig, and Osler were great, but it is to be hoped that the English and American Society of Friends, whose members have done such admirable work in restoring the waste places of France and Belgium, will be able to sow the seeds of the humanities and to illumine the dark places of Central European thought with the light of modern British and American thought. Books have ever, since they began to be written, been the delight of cultivated minds, and the great thinkers of the world have left on record the praise of books, the panegyric of Cicero, with which he astonished the courts in an action of contested citizenship, is still one of the great passages of literature, even as Mackail says, "the abiding motto and blason of literature itself." Such studies, says Cicero, "occupy our youth, divert our old age, embellish the times of our weal, offer refuge and consolation in time of woe, delight us at home and do not stand in our way in public life, pass with us the night watches, travel with us abroad, are with us in the country." Such is the praise of books, but many years before Cicero a greater mind still had seen that books are not everything. In his dialogue "Phædrus," Plato makes Socrates say that "only in principles of justice, and goodness, and nobility taught and communicated orally and written in the soul, which is the true way of writing, is there clearness and perfection, and seriousness." An old and famous paradox says, "Knowledge cannot be taught." It may be that the fire of war has begun to purge out the old megalomania from the Central European Empires, and that the provision of books will enable teachers of those countries to appreciate right thinking. Forgiveness of enemies is a Christian duty, but forgiveness connotes repentance on the part of the enemy, and at present there is little sign of this. Still, the experiment is worth trying.

I am, Sir, yours faithfully,
H. P. C.

April 23rd 1920

SMALL POX IN GLASGOW.—A mild outbreak of small pox has occurred in Glasgow during the last few weeks. The first cases were noted early in March, and to date there have been 28 admissions to hospital. A great majority of the patients are children. In view of the steady decrease of infantile vaccination, it is estimated that not more than half the children born are protected, as against a proportion of 84 per cent prior to the Vaccination Act, 1907. Special arrangements have therefore been made to provide and encourage vaccination among the unprotected, and the response has so far been satisfactory. In view of the prevalence of small pox the corporation have resolved that cases of chicken pox are to be notifiable from May 1st until July 31st.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surgeon Rear-Admiral A. G. Wildey is placed on the retired list.

F. R. McCambley is granted a commission as Surgeon-Lieutenant (D.).

ARMY MEDICAL SERVICE.

TERRITORIAL FORCE RESERVE.

Col. S. S. Hoyland, having attained the age limit, is retired, and retains his rank, with permission to wear the prescribed uniform.

ROYAL ARMY MEDICAL CORPS.

Lieut.-Col. J. H. Brunskill retires on retired pay.

Lieut.-Col. F. S. Penny relinquishes the temporary rank of Colonel.

The undermentioned relinquish the acting rank of Lieutenant-Colonel: Major L. A. A. Andrews; Major and Bt. Lieut.-Col. C. R. Sylvester-Bradley; Temp. Major W. H. G. Aspland; Temp. Capt. J. F. Robertson.

Major E. B. Lathbury, O.B.E., to be acting Lieutenant-Colonel.

The undermentioned relinquish the acting rank of Major: Capt. and Bt. Major W. F. Christie; Capts. R. S. Cumming, H. Bedingfield; Temp. Capts. A. E. Atkinson, M. Bates, A. Grant, F. R. Sturridge, H. G. Kilner, N. E. Kendall.

To be acting Majors: Capt. D. H. C. MacArthur; Temp. Capt. C. R. B. Von Braun.

Capt. A. L. Aymer resigns his commission and is granted the rank of Major.

Officers relinquishing their commissions:—Temporary Captains granted the rank of Major: A. Grant, J. A. Mackenzie (acting Major), W. C. Sharpe. Temporary Captains retaining the rank of Captain: F. G. Cross, K. R. C. Hallowes, F. E. Sprawson, J. S. Martin, W. L. Thomas, H. O'H. O'Neill, W. I. Adams, E. G. Grove, H. J. Knox, F. A. Ross, T. F. Lumb, E. Sakoschansky, E. Lewis, W. Bannatyne, W. Boyd.

SPECIAL RESERVE OF OFFICERS.

Capt. C. Lovell relinquishes the temporary rank of Major.

Captains relinquishing the acting rank of Major: G. H. Stevenson, J. A. Hill, J. A. Stewart.

Capt. C. A. McGuire relinquishes his commission and retains the rank of Captain.

TERRITORIAL FORCE.

Major (acting Lieut.-Col.) T. L. Fennell relinquishes the acting rank of Lieutenant-Colonel on ceasing to be specially employed.

Capt. J. B. Bate is seconded under para. 112 T.F. Regulations.

Capt. F. W. K. Tough to be Major.

Capt. (acting Major) W. T. Harkness relinquishes the acting rank of Major on ceasing to be specially employed.

1st Northern General Hospital: Major (acting Lieut.-Col.) D. W. Patterson relinquishes the acting rank of Lieutenant-Colonel on ceasing to be specially employed.

TERRITORIAL FORCE RESERVE.

Major W. Kirkpatrick, from 1st Southern General Hospital, to be Lieutenant-Colonel.

ROYAL AIR FORCE.

Medical Branch.—The undermentioned are transferred to the unemployed list: Capts. J. P. Hennessy, J. Ferguson, R. W. Pritchard, C. F. Eminson, H. L. H. Greer, W. Lumley, D. J. Cannon, M. Hyman; Lieut. R. H. Parry.

INDIA AND THE INDIAN MEDICAL SERVICES.

Lieut.-Col. Sarbadhicary has been elected a Fellow of the Calcutta University. Major R. E. Wright, Bacteriology Department, has been posted to Madras. Capt. P. J. Edmunds is appointed Physician, Wireless Branch, India Telegraphs. Lieut.-Col. G. T. Birdwood, civil surgeon, Lucknow, has been granted privilege leave combined with furlough on full average salary for the total of eight months. Lieut.-Col. L. G. Fischer, civil surgeon, Dehra Dun, has been granted privilege leave. Major J. T. Parkinson, officiating superintendent, Bareilly Central Jail, has one month's leave. Lieut.-Col. J. C. H. Leicester has been appointed permanently Professor of Midwifery, Medical College, Calcutta. Capt. E. S. Phipson has been confirmed as Health Officer, Simla.

THE Society of Apothecaries of London has subscribed £10 10*s*. to the Keats Memorial Fund. The poet was one of the earliest licentiates of the society; having been examined by the well-known Dr. Brunde, he qualified in 1816.

Obituary.

THOMAS JACKSON, B.A. LOND., M.R.C.S., J.P.,

CORONER FOR CROYDON.

THE death of Dr. Thomas Jackson, of Thornton Heath, will be felt by a wide circle. Born at Torrington, Devon, in 1846, he was educated at his father's private school and then at New College, Hampstead, to become a Congregational minister, taking his B.A. Lond. in 1867. Soon afterwards he decided for a medical career, studying at the Middlesex Hospital, from which in 1877 he qualified L.S.A. and L.R.C.P. Edin., and M.R.C.S. Eng. in the following year. After serving as resident obstetric officer at his hospital he settled in practice at Thornton Heath, and at once made his mark as a citizen. He was one of the first aldermen for the newly-formed county borough of Croydon, and sat on the first bench of borough magistrates. But it is as coroner that he will be best remembered. From 1889 when he was appointed, until the day of his death, on only a single occasion was the necessity of holding an inquest ordered by him called in question, and subsequent events then proved his judgment to be correct.

A colleague sums up his character thus: He was a man of varied interests, a great lover of gardening, a fine conversationalist, a keen politician, a scholar, full of humanity and kindliness, his outstanding characteristic being his sane outlook on life. The smile of the man was a benediction, but if that suave manner misled a witness at an inquest into thinking he had a soft proposition to deal with he soon discovered his error.

Of Dr. Jackson's other civic activities it may be mentioned that he was instrumental in securing Grange Park for his fellow citizens as a recreation ground, and in the establishment of the Polytechnic and the Free Library. He was the founder of the Croydon Ratepayers' Association, and an unfailing supporter of the Liberal party in a constituency which has never returned a Liberal Member to Parliament.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following candidates have satisfied the examiners in both parts of the Examination in Sanitary Science:—

Alured Charles Lowther O'Shea Bilderbeck, James Brown, William George Clark, Margharita Mary Lamont Couper, Henry Speldewinde de Boer, Eric Alfred Fiddian, Alexander Fraser, George Makinson Heydon, George Gordon Johnstone, *John Burman Lowe, Peter Alexander McCallum, Jessie Brown Maclachlan, Philip Sydney Marshall, William Percival Mulligan, Albert Rutherford Paterson, Dawson Cameron Robertson, John Bevil Grenville Skelton, Victor Farrar Soothill, and *Meredith Blake Robson Swann.

* Distinguished in the Application of Sanitary Science.

UNIVERSITY OF GLASGOW.—The following degrees were conferred on April 20th:—

Doctor of Medicine (M.D.).—Daisy Annabella Murdoch Clark (Mrs. Gale) (with commendation).

Doctor of Science (D.Sc.).—John William McNee and John Boyd Orr.

Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.).—Alexander Mitchell Beaton, Alexander Kidd Begg, John William Stewart Blacklock (with honours), Richard Ryther Stancer Bowker, Archibald Donald Brown (with commendation), Annie Burns Cameron, John Parker Chisholm, George Michael Cooper, William Norman Duguid, Robert Fletcher, Thomas Fletcher, Robert Adam Forsyth, Robert Gold Howat (with commendation), Thomas Downie Hunter, George Jamieson, Chung Un Lee, Barnett Levine, Alexander M'Cheyne Macintosh, Peter Alexander Mackay (with commendation), William M'Kendrick, John M'Kean Maxton, John Spence Meighan, Marjorie Mitchell, Thomas Fraser Noble, Peter Crawford Rankin, Robert Scott Reid, Joseph Sachs, Marguerite Linck Sclanders, Cecilia Shiskin, Thomas Stewart Stirling, Alexander Strang, Herbert Arnold Summers, John Leonard Turpie, and John Dora Williamson

AT the meeting of the Medico-Psychological Association of Great Britain and Ireland, on May 20th, the First Maudsley Memorial Lecture will be delivered by Sir James Crichton-Browne, at 3.30 P.M., at the Royal Society of Medicine.

Ancoats Hospital, Manchester, is making an appeal to the public Of the £50,000 needed to build and equip a nurses' home and pay off an overdraft of £9000, so far £13,555 have been promised

CLEANSING OF SHELL FISH.—At the last meeting of the Exeter port sanitary authority it was reported that the Ministry of Health had promised to provide tanks for the cleansing of shell fish in the Exe estuary

THE 48TH GENERAL HOSPITAL, SALONIKA—The opening of this hospital is to be commemorated by the holding of a dinner in London on June 24th Officers who have been connected with the unit are asked to communicate with Dr B Holroyd Slater, St Luke's Hospital, Bradford

MEDICO LEGAL SOCIETY—A meeting of this society will be held at 11, Chandos street, London, W, to day, Friday, April 30th, at 8 30 P M, when a paper will be read by Dr Mackenzie Wallis, on the Purity of Ether and Chloroform in its Relation to Anæsthesia, and specimens will be shown by Dr B H Spilsbury

RONTGEN SOCIETY—A special general meeting of this society will be held on Tuesday, May 4th, at 8 15 P M, at the rooms of the Medical Society of London, 11, Chandos street, Cavendish square, London, W A paper on Some Problems in the Action of Radiation upon Tissues will be read by Professor Sidney Russ, the President, and demonstrations on the transmission of speech by light and on a new portable viewing lantern will be given by Professor A O Rankine and Dr H A Eccles respectively

A THIRD post graduate course of instruction in the diagnosis and treatment of venereal disease is being arranged by Mr. K M Walker at St Bartholomew's Hospital Clinic, Golden lane, E C, established by the Corporation of London The course will be held on Thursday afternoons at 5 30 P M, commencing Thursday, May 13th The beds attached to the clinic are available for the reception and study of suitable cases in addition to work in the out patient department There are still a certain number of vacancies Any medical practitioner wishing to attend is invited to send his name to the secretary, National Council for Combating Venereal Diseases, 81, Avenue Chambers, Vernon place, Southampton row, W C 1

THE LATE DR. E. S H. GILL—Eustace Stanley Hayes Gill, who died recently at Shaftesbury House Private Asylum, Formby, where he had lately taken over his father's duties as medical superintendent, was a well known member of the medical profession in Liverpool and the surrounding districts Educated at Liverpool University, he graduated M B, Ch B in 1906, and was for a time resident medical officer at the Brownlow Hill Workhouse Hospital A clever actor, he ungrudgingly gave his services wherever demanded in the name of charity, and it was while attending a dress rehearsal that he was taken ill, dying two days later Dr Gill leaves a widow and four children

UNIVERSITY OF MANCHESTER APPEAL—The intensive and extensive crusade undertaken to raise £500 000 on behalf of the university, to which we referred in THE LANCET on April 17th, is being carried on with great vigour in and around Manchester In the lay press there appear frequent pithy expositions of the work of various departments of the university on behalf of the community as well as in the advancement of learning Amongst topics dealt with by way of enlightening the proletariat and enlisting contributions from the public are such matters as "the training of the engineer," "the school of commerce," "extra mural teaching and what it means," "exclusion of women for lack of funds," "Manchester and its medical school as a great centre for clinical instruction," "education and the new democracy" This is the first appeal of its kind made on behalf of any British university, and whatever the financial result the university means to make it plain that it is the servant of the public without distinction of class Dr Alexander Irvine a persuasive speaker, makes known the needs and possibilities of the university by short addresses between the acts at theatres music halls, and kinema palaces, and in the dinner hour to the working man It would seem that the audiences are not consumed with enthusiasm for the university, but they are nevertheless responsive to reasoned appeals for help Another worker is touring the neighbouring towns in a car and addressing meetings of working class audiences If the result of the appeal does not come up to the standard expected it will not be through slackness in advertisement To the hoardings of the city is affixed a striking poster setting forth excerpts from letters supporting the appeal, with effigies of the five writers selected—Mr Clynes, Viscount Bryce, Lord Sumner, Lord Haldane, and Mr Fisher Outside the university is affixed a sort of barometric ladder as high as the Whitworth Hall, to show the rise of the fund At present a figure somewhat over £160 000 has been reached

PEOPLE'S LEAGUE OF HEALTH—The Lord Mayor of London will preside at a meeting to be held at the Mansion House on May 11th, at 3 P M, for the purpose of bringing before the lord mayors and mayors of the country the objects and scope of the league

PRESENTATION TO A MEDICAL MAN—On behalf of the inhabitants of Eastbourne the Duke of Devonshire recently presented Mr Charles O'Brien Harding, M R C S, L R C P, mayor of Eastbourne from 1915 to 1919, with an oil painting of himself to be hung in the town hall On the retirement of Mr Harding from the mayoralty in November last the honorary freedom of the borough was conferred upon him—

> ' In recognition of his distinguished services to the borough as a member of the town council during the past 23 years, as a justice of the peace for 16 years and as mayor of the borough for five years and in particular for the impartial dignified, and efficient manner in which he performed the many additional onerous, and exacting duties imposed upon him by reason of the Great War

CENTRAL MIDWIVES BOARD—A special meeting of the Central Midwives Board was held at Queen Anne's Gate Buildings, Westminster, on April 21st, with Sir Francis H Champneys in the chair The names of several midwives were struck off the Roll, the following charges amongst others having been brought forward —

> Being in attendance at a confinement the midwife neglected to provide for or to give all necessary directions for securing the cleanliness and comfort of the mother and child as required by Rule E 12, she neglected to wash the patient s external parts with soap and water, and to swab them with an efficient antiseptic solution as required by Rule E 8 and she neglected to remove the soiled linen from the neighbourhood of the patient and from the lying in room as soon as possible after the confinement as required by Rule E 11 A presentation being abnormal and the patient suffering from excessive bleeding the midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required as provided by Rule E 21 (3) and medical aid having been sought for the patient she neglected to notify the local supervising authority thereof, as required by Rule E 22 (1) (a) A midwife was guilty of negligence and misconduct in the following respects she neglected to examine the placenta and membranes as required by Rule E 10 and she habitually employed an uncertified person to visit patients contrary to Section 1 (4) of the Midwives Act 1902 A child suffering from inflammation of and discharge from the eyes during her attendance, a midwife did not explain that the case was one in which the attendance of a registered medical practitioner was required as provided by Rule E 21 (5), and she did not on each occasion, when attending the patient wear a clean dress of washable material as required by Rule E 2 A midwife was not scrupulously clean in every way, as required by Rule E 2 and did not carry with her, when called to a confinement the bag or basket appliances or antiseptics required by Rule E 3

WELSH NATIONAL SCHOOL OF MEDICINE—The inauguration of a scientific section of the medical students' club marks an important step in the progress of what it is expected will soon become an important teaching organisation The ceremony was marked on April 23rd by an address given by Major General Sir Robert Jones The school is in process of being organised on the unit system of professors, and the Principal of the College announced that the full curriculum might be in action for the session 1921–22 The guests of the students' club were numerous, and, in addition, included the Lord Mayor, Sir William Seager, Sir John L Thomas, and the Marchioness of Bute, who is at present an anatomy student in the school Sir Robert Jones paid a tribute to the students for the step they were that day taking, and said that the future before the Welsh National School of Medicine ought to be a great one A medical school must have a sufficiency of clinical material and the speaker held that the supply could only be provided by the establishment of hospital accommodation outside big cities He held that the King Edward VII Hospital splendidly equipped as it was, could not on its present site meet the need, and advocated that while this institution should be a centre for clinics and for emergency and major beds, more accommodation should be placed in the fresh air and sunshine on such a site as he understood was likely to become available on the Rookwood Estate at Llandaff The war had shown that expensive buildings were not necessary, indeed, they were rather disadvantageous than otherwise Every type of case benefited by exposure to fresh air, and he dwelt upon its advantages in his own particular specialty, that of orthopædics He considered 1500 beds necessary as compared with 400 provided by the present hospital He pointed out that the scheme he advocated was already partially in existence, since mental cases, fever cases, and cases of phthisis were already treated outside the city, and only required to be linked up with the central hospital This connexion had recently been established for mental cases by means of out patient clinics He closed his remarks with a tribute to the Prince of Wales Hospital, initiated during the war for the after care of limbless warriors, and now to be devoted to the needs of the civilian population

GENERAL NURSING COUNCIL.—The nominees of the Board of Education on the Council are Hon. Mrs. Eustace Hills and Miss M. J. Tuke, Bedford College.

FROM to-day notifications received by the London medical officers of health of acute primary pneumonia, acute influenzal pneumonia, malaria, dysentery, trench fever, acute encephalitis lethargica, and ophthalmia neonatorum (whether notified by a medical practitioner or by a certified midwife) must within 12 hours of receipt be forwarded by the medical officer to the Metropolitan Asylums Board. The obligation already applies to acute polio-encephalitis and the usual notifiable infections.

THE NATIONAL HEALTH SOCIETY.—Sir George Newman, Chief Medical Officer of the Ministry of Health, delivered on April 22nd, before the National Health Society, the annual Priestley Memorial Lecture, taking as his subject "The Place of Public Opinion in Preventive Medicine." The lecture was preceded by the presentation of diplomas to the society's students by Princess Christian. Sir James Crichton-Browne, chairman of the society, presided in the absence of the Minister of Health. Among those present were: Sir Rickman and Lady Godlee; Sir William Church; Surgeon Rear-Admiral Sir Robert Hill, Medical Director-General of the Admiralty; Sir John Goodwin, Director-General A.M.S.; Sir E. Ray Lankester; Sir David Ferrier; Sir Malcolm and Lady Morris; Mrs. H. A. L. Fisher; Dr. Maurice Craig; Professor Kenwood; Dr. Higgins, medical officer of health, St. Pancras; Mrs. Kendal; Sir John MacAlister; Sir Frederick Mott; and Dr. Charles Porter, medical officer of health, St. Marylebone. A large gathering of members, friends, and subscribers of the society, and past and present students, filled the Robert Barnes Hall at the house of the Royal Society of Medicine.

ST. FRANCIS HOME.—An appeal is being made for the sum of £8000 for the purchase of a suitable house and its conversion into a nursing home, fully equipped, for the treatment of patients with small fixed incomes. When the home is once started it should be self-supporting, even when fees are kept down to a very low level, since the actual nursing is to be provided by a Church of England sisterhood who are prepared to give their services. The home will be run on ordinary nursing home lines, with private rooms, and patients will be able to choose their own physicians and surgeons if so desired. The medical signatories to the appeal include Mrs. M. Scharlieb, Sir Francis Champneys, Sir Malcolm Morris, and Mr. E. B. Turner. Contributions should be sent to Major Campbell, the honorary treasurer, St. Francis Home Fund, at 3, Southwell-gardens, S.W. 7, and any inquiries to the honorary secretary, Miss H. Vansittart, 34, Queen's Gate-terrace, S.W. 7.

CONJOINT BOARD OF SCIENTIFIC SOCIETIES.—The third annual report for the year 1919 gives evidence that the Board continues to discharge useful work. During the year there was a danger that supplies of casein and glue would fall short, and that aeroplane manufacture would suffer thereby. The Board came to an arrangement with the Air Group of the Ministry of Munitions, and carried out a research into the nature, functions, and manufacture of adhesives which resulted in the discovery of useful new adhesives. In addition to this, Dr. Schryver and his colleagues devised improvements in the manufacture of casein which effect a considerable saving in material and an improvement in its quality. The Committee on the Water Power of the Empire, with Sir Dugald Clerk as its chairman and Professor A. H. Gibson as secretary, drew up a second report, in which they are able to claim that they have stimulated interest in water power investigations in many parts of the Empire. A proposal has been put forward to hold an Imperial Water Power Conference in London, as the lack of facilities in universities and technical institutes for the specialised training of young men in hydro-electric engineering is noticeable. An elaborate report on the advisability or otherwise of the compulsory adoption of the metric system, drawn up by a committee with Mr. Wilson-Fox as chairman and Mr. A. R. Hinks as secretary, was discussed at a special meeting of the Board called for the purpose. The report emphasises the practical difficulties which would confront compulsory adoption, especially during the war. Other pieces of work summarised in the report relate to such subjects as the supply of timber for aeroplanes, the establishment of geophysical and petro-physical institutes, and the place of science in warfare. The Board has also taken its share in the discussion of the formation of national and international research councils and in advocating the publication of a work devoted to the mineral resources of the Empire. The *Bulletin*, which is printed and issued to the conjoint societies and the members of the Board, gives in a comprehensive form a forecast of the meetings of the societies and an early announcement of the papers to be read thereat.

Parliamentary Intelligence.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 21ST.

Promotion of Surgeon Captains.

Sir WATSON CHEYNE asked the First Lord of the Admiralty whether he was aware that in the April Navy List only four officers were shown under the heading of surgeon rear-admiral, and that no surgeon captains had been promoted to fill the two vacancies created by the retirement in February last of Surgeon Rear-Admiral Dimsey, D.S.O., and the addition of one surgeon rear-admiral to the list as announced in March; and whether he was aware of any reason why surgeon captains should not be promoted at once on the occurrence of vacancies in the same way as captains in the executive branch are promoted to fill vacancies in the Rear-Admirals' List.—Sir J. CRAIG (Parliamentary Secretary to the Admiralty) replied: The question of promoting officers to fill the vacancies on the Surgeon Rear-Admirals' List is now under the consideration of the Board of Admiralty, and it is hoped to announce the promotions at an early date. With regard to the second part of the question; the reason is that promotion to the rank of surgeon rear-admiral is by selection, whereas promotion to rear-admiral is normally made by seniority.

Medical and Veterinary Students' Grants.

Sir MARTIN CONWAY asked the Minister of Labour whether ex-army students at the University of Liverpool, proceeding through a five years' course to a degree in veterinary surgery, might be granted an equal subsidy to that given to medical students, seeing that for the first two years the standard required for both classes was identical, and training practically identical, and that the expense to the student for both was the same.—Dr. MACNAMARA replied: As stated in the reply to my honourable friend's question of March 24th, the maximum annual awards permissible under the Training Grant Scheme for students proceeding to veterinary degrees at the University of Liverpool are the same as for medical students at the institution. The scheme provides machinery whereby a student who feels that the amount of his award is inadequate can appeal for an increase within the maximum permissible. Actually, owing to the continued high cost of living, the average awards now being made are on a somewhat higher scale than they were three or four months ago. In view of the fact that cases are dealt with individually, and that adequate machinery exists for remedying defects in assessment of grants, a general equalisation does not seem to be called for. I might add, however, that instructions have been given to the District Director to make fuller inquiry into the question, which will be further considered on receipt of his report. If my honourable friend has in mind any individual case of hardship I shall be glad if he will furnish me with particulars of it.

Medical Supervision of Elementary Schools.

Mr. GRATTAN DOYLE asked the Minister of Health if his attention had been called to the necessity of closer medical supervision of elementary schools; and if he could arrange for a weekly attendance of a doctor at each school, when he could pass the children in review, thereby anticipating illness and improving the health of the children and also saving parents loss of time, worry, and expense.—Dr. ADDISON replied: My honourable friend may be assured that the necessity for doing all that is practicable in this matter is fully recognised; but it is not, I think, necessary or practicable to ask authorities to arrange for the weekly attendance of school doctors at each school, as suggested by my honourable friend. I may remind him also that in 310 out of the 318 local education authorities in England and Wales there are school nurses performing some of the functions to which he refers.

Mr. BILLING: Will the right honourable gentleman consider the advisability of introducing tooth-cleaning drill in the mornings for small children, having regard to the extraordinarily beneficial effect clean teeth have on small children?—Dr. ADDISON: I think it is already in operation.

Mr. IRVING: Is the right honourable gentleman aware that in New York, and certainly in some countries, a daily review of children takes place; and is it not a fact that there is a daily variation in the health of children?—Dr. ADDISON: That is quite so; it depends on the reviews you have. There are not enough doctors and nurses in the country to review every child.

Mr. IRVING: In the cases I have mentioned there are men qualified.—Dr. ADDISON: The honourable gentleman may be assured that the school teachers review these children every day, and the children are very well trained and instructed in this matter. I do not think it requires special action.

Dental Legislation

Mr RAFFAN asked the Minister of Health if he could now state whether it was the intention of the Government to introduce legislation during the present session of Parliament for the purpose of carrying out the recommendations of the departmental committee on the Dentists Act, 1878 —Dr ADDISON replied I am not yet in a position to make a statement on this matter, but I hope to do so very shortly, possibly before Whitsuntide

Meat Inspection and Public Health

Mr JAMES BELL asked the Minister of Health if he was aware of the lack of a uniform system for the inspection of meat, and that the want of such a system constituted a menace to the public health, and whether he would arrange for the establishment of a uniform system which would include the ante mortem and post mortem examination of all animals intended for human consumption —Dr ADDISON replied I am aware of the desirability of securing uniformity in meat inspection in the interests of public health, and I am considering what steps can best be taken and what further powers may be necessary to that end

Alleged Deaths from Starvation

Commander Viscount CURZON asked the Minister of Health whether his attention had been called to the case of a man, his wife, and one child who were reported to have died of starvation in Bermondsey Hospital, whether he could state how such a thing was possible, and what action he had taken —Dr ADDISON replied Yes sir Immediately my attention was called to the case I instructed one of my inspectors to report upon it The medical superintendent of the infirmary reports that the man, his wife, and a child of 4 years old were admitted to the infirmary on April 10th, all three suffering from pneumonia The man died from pneumonia on the 13th The wife was delivered of a still born child on April 12th, and died of pneumonia on the 13th The child of 4 is still in hospital I propose to make further inquiries into this case

Mr W THORNE Will the right honourable gentleman on making inquiries strictly investigate the houses in which the people are living?—Dr ADDISON I shall certainly do that

Mr BILLING Will the right honourable gentleman consider the advisability, in calling for a report on the cases that still exist in London, of seeing whether some comprehensive scheme could be introduced into the Poor law administration with a view to preventing death rather than burying people after death?—Dr ADDISON All I can say is that for several months we have been considering a comprehensive scheme relating to Poor law reform and other matters arising out of it.

Circular 204 and Home Treatment

Mr IRVING asked the Pensions Minister if he was aware that prior to the issue of Circular 204 (revised), issued from the Ministry of Pensions, Feb 6th last, a disabled soldier, when placed on home treatment by the medical referee, and certified by such referee to be unable to work on account of his disability, caused or aggravated through war service, automatically became entitled to allowances equal to 100 per cent disability for the period of his incapacity for work, that according to this Circular 204 (revised) of Feb 6th, all cases of home treatment had now to be submitted to the Deputy Commissioner of Medical Services of the area for his approval or otherwise, if he would state the reasons for this change, so much to the disabled soldier's disadvantage, and if he could see his way to revert to the practice of the last three years, whereby a man certified as being incapable of doing any work on account of such a disability, and recommended for home treatment should be automatically entitled to benefit without reference to an area deputy commissioner of medical service —Major TRYON (Parliamentary Secretary to the Ministry of Pensions) replied Circular 204 does not involve any modification of the rights of disabled men under the pensions warrant The primary function of the Deputy Commissioner of Medical Services under that circular is to secure for the men the form of treatment most suitable to their disabilities Many men have in the past been recommended for home treatment who would have been better treated in one or other of the special institutions of the Ministry, as to which medical referees are of necessity not so well informed as the medical officers of the Department It is also the function of the Deputy Commissioner to assist in the protection of public funds by ensuring that treatment allowances are confined to those cases for which they were intended by Article 6 of the Royal Warrant My right honourable friend is unable to entertain the suggestion contained in the last paragraph of the question

THURSDAY, APRIL 22ND

Retired Military and Naval Medical Men at Pensions Ministry

Mr ROBERT YOUNG asked the Pensions Minister whether a considerable number of retired Regular naval and military medical men employed by the Ministry were in receipt of pensions from £600 to £1000 a year, whether demobilised temporary doctors whose sole source of income such an appointment frequently was were still in need of employment, and who through the appointment of these pensioned officers were frequently precluded from some of the better appointments, and whether pre war rank was often considered as a sine qua non of medical efficiency —Major TRYON replied Of the 12 retired Regular naval and military medical men employed as full time medical officers in the Ministry, six are in receipt of pensions of £600 a year or more This represents a little more than 1 per cent of the total number of medical men employed, and it is not therefore the fact that the employment of these gentlemen has any appreciable effect on the prospects of demobilised temporary medical men The medical officers of the Ministry are selected according to their qualifications for the particular work to be performed

Pensions of Blinded Soldiers

Mr FOREMAN asked the Pensions Minister if he would inform the House how many soldiers totally blinded in the war were now in receipt of pensions, whether there were any such blinded soldiers who were not receiving pensions, if so how many, if he would state the reasons for such non receipt of pensions, whether any responsibility was accepted by his Ministry for keeping in touch with such blinded men, even if they did not receive pensions to see that they did not fall on evil days, what was the maximum weekly pension for disablement by blindness, and if any investigations were made to ascertain if it was adequate —Major TRYON replied Approximately 1300 soldiers discharged for total blindness have been pensioned under the Royal Warrant, and 110 have been refused pensions The latter are men whose blindness arose from causes not connected with their military service, or was due to their own serious negligence or misconduct All men discharged for blindness are sent to "St Dunstan's" (or in Scotland to Newington House, Edinburgh), where they are trained in a new occupation, suitable to their condition before returning to their homes After their return the institutions mentioned continue to keep in touch with them by means of local representatives The disablement pension for total blindness varies from 40s to 60s according to rank together with a constant attendant allowance of 10s to 20s a week, a wife's allowance of 10s a week, and additional allowances for children

Mr BILLING Can the honourable and gallant gentleman say what is being done with the 110 odd blinded men who have not been pensioned, whether anything was being done for them or whether they were being thrown on the rates?—Major TRYON If they are at "St Dunstan's" they are provided for

Mr BILLING What can they do after they leave St Dunstan's?

Colonel C LOWTHER Is it a fact that no provision is made for blind men who have lost their sight in the service of their country?—Major TRYON If they lose their sight in the service of their country they are provided for

Prime Minister and Blind Deputation

Mr WATERSON asked the Prime Minister if it was his intention to personally interview the deputation of the blind on the 26th or 27th of this month —Mr BONAR LAW replied The Prime Minister has informed the deputation that if he is in London when they arrive he will be pleased to receive them, and in the event of his being still away he suggested that I should receive them on his behalf

Vaccination Officers

Mr WATERSON asked the Minister of Health the approximate cost of the vaccination officers in 1913 and 1919 respectively —Dr ADDISON replied The approximate cost of public vaccination in England and Wales was £168 000 in the financial year 1912-13 and £112 000 in the financial year 1918-19 I have no separate information as to the cost of the vaccination officers

Mr WATERSON asked the Minister of Health if it was his intention to repeal the Vaccination Acts?—Dr ADDISON No Sir

MONDAY APRIL 26TH

Epileptic Officer's Claim for Pension

Mr JAMESON asked the Secretary for India if he was aware that a lieutenant in the 74th Punjabis, whose name had been privately communicated passed through Sandhurst as medically fit in 1912, developed epilepsy, of which he had no previous symptoms, when on service in China after an attack of fever in 1915 was invalided out for epilepsy in 1916, and refused a pension on the ground that the epilepsy was not the result of military service, and if he would take steps to have a pension granted —Mr MONTAGU replied Under the Indian Army Regulations an officer is not eligible for pension who is invalided out after less than three years' service in India in the Indian Army unless the disability is certified by the proper medical authority as having been caused by duty. The case referred to was very carefully considered, but the medical authorities could not regard the epilepsy as having been caused by military service, and the officer was therefore not awarded a pension. He was, however, granted a gratuity of one year's British pay.

Welfare of the Blind.

Dr. ADDISON presented a Bill to promote the welfare of blind persons. No explanation of the Bill was given, but it is understood that the chief proposal of the measure is that blind persons who are unable to work should be entitled to receive a State pension of 10*s.* per week between the ages of 50 and 70 years on the same conditions as those attaching to the receipt of old age pensions. The Bill will also, it is stated, provide for the registration of all voluntary institutions making public appeals for funds. Further training facilities for the blind are to be provided through certain local authorities.

TUESDAY, APRIL 27TH.

National Health Insurance Bill.

The National Health Insurance Bill was considered by Standing Committee A of the House of Commons.

Mr. G. LOCKER-LAMPSON moved an amendment designed to secure that local authorities providing treatment for persons suffering from tuberculosis should co-opt persons with experience of the working of tuberculosis treatment.

Dr. ADDISON explained that the purpose of taking sanatorium benefit out of the National Health Insurance Bill was that health services were contemplated which would more conveniently deal with tuberculosis. The amendment was withdrawn.

Major FARQUHARSON moved to insert after Clause 8 a new clause as follows:—

> 1. Any medical practitioner aggrieved by a decision of the Minister, or of any special body through which the powers and duties of the Minister, under Section 15, Subsection (2) (*b*), of the Act of 1911, are exercised, to remove his name from any list of medical practitioners may appeal against the decision to the High Court within the time, and in the manner, and on the conditions directed by the rules of court. 2. The costs of any such appeal shall be in the discretion of the court, and no appeal shall be allowed from any order or decision of the court in any such appeal.

Dr. ADDISON replied that no medical man was compelled to go on the panel, and he could come off it when he liked. When there was this freedom of contract he did not see that there was any case for appealing to the High Court. A medical man before he was removed from the panel would have an opportunity to lay his case before his professional brethren.

The new clause was withdrawn and the Committee stage of the Bill was concluded.

Homes for Mental Cases.

Major ENTWISTLE asked the Pensions Minister if he would say how many homes of recovery were under his control, how many mental cases had passed through, and how many were receiving treatment.—Mr. MACPHERSON replied: There are 20 such institutions under the control of the Ministry, and 2383 men are at present under treatment. I am making inquiry with regard to the second part of the question, and will inform my honourable and gallant friend of the result.

Mental Cases at Warrington and Whitchurch.

Major ENTWISTLE asked the Secretary for War and Air if he would state how many mental cases passed through Warrington and Whitchurch hospitals; how many mental cases had been reported to his department since August 4th, 1914; how many had recovered; how many died; and the disposition of the remainder.—Mr. CHURCHILL replied: The number of mental cases which passed through the two hospitals mentioned were: Warrington, 8410 up to March 31st, 1920, the date of the latest report; Whitchurch, 1862 up to Jan. 2nd, 1920, the date on which the hospital was closed. The figures asked for in the remainder of the question will not be available until the Medical History of the War is published, which will not be for some two or three years. The following details, however, are available with regard to the patients treated in the two hospitals referred to in the question:—Warrington (from the date of opening to Dec. 31st, 1919): Number of cases treated, 8127; discharged to their homes recovered, 3657; discharged to asylums, 1026; transferred to other military mental hospitals or repatriated overseas, 2433; died, 108; remaining in hospital, 903. Whitchurch (from date of opening to Oct. 31st, 1919): Number of cases treated, 1862; discharged to their homes recovered, 1102; discharged to asylums, 446; died, 33; remaining in hospital, 281.

Death-rate of Old-age Pensioners.

Mr. W. THORNE asked the Minister of Health (1) the number of old-age pensioners for the years ending March, 1918, 1919, and 1920; and (2) the death-rate of old-age pensioners for the same years.—Mr. BALDWIN (Secretary to the Treasury) replied: The number of old-age pensions payable on the last Friday in the year ended March 31st, 1918, was 943,077, and in the year ended March 31st, 1919, 920,198. The number for the year ended March 31st, 1920, is not yet available, but the number payable on the last Friday in December, 1919, was 926,631. The corresponding figures of the pensioners of whose death information has reached the pension officer are as follows: In the year ended March 31st, 1918, 94,478; in the year ended March 31st, 1919, 105,746; in the nine months ended Dec. 31st, 1919, 68,550.

Financial Provision for Sanatorium Benefit.

Major D. DAVIES asked the Minister of Health what arrangements were being made to provide the money for sanatorium benefit, which, under the National Health Insurance Bill, 1920, it was proposed to take out of the hands of the Insurance Committees.—Dr. ADDISON replied: The financial arrangements which will be necessary on the termination of sanatorium benefit are under consideration, and I hope to be in a position to make an announcement on this subject at an early date.

Appointments.

COFFIN, S. W., M.R.C.S., L.R.C.P. Lond., has been appointed Anæsthetist to the Hospital for Diseases of the Throat, Golden-square.

JEFFERISS, I. M., L.R.C.P. Lond., M.R.C.S., Medical Officer of Health for Okehampton (Devon).

PARKINSON, JOHN, M.D. Lond., M.R.C.P. Lond., Assistant Physician to the National Hospital for Diseases of the Heart.

TAYLOR, J., M.R.C.S., L.S.A., Honorary Consulting Radiologist to the Bristol Royal Infirmary.

Certifying Surgeons under the Factory and Workshop Acts: STEWART, F. M., L.R.C.P., & S. Edin. (Hull); MCCALLUM, J. D., M.B., Ch.B. Glasg. (Lochgilphead).

Vacancies.

THE Chief Inspector of Factories, Home Office, S W, gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Tarbert and at Yatton

Births, Marriages, and Deaths.

BIRTHS.

ALEXANDER.—On April 25th, at Cade House, Riverhead, Sevenoaks, the wife of J Finlay Alexander, M A, M D Camb, *of a son*

ARONSON.—On April 21st, at the Mill House, Chipperfield, King's Langley, Mollie wife of Hugh Aronson, of a daughter

CHAMBERS.—On April 19th, at a nursing home in London, the wife of Captain G O Chambers, M C, R A M C, *of a son*

KILNER.—On April 21st, at Albert-crescent, Bury St Edmund's, the wife of H Goff Kilner (late Major, R A M C, Croix de Guerre), of a daughter

PURSER DAVIES.—On the 22nd April, at a nursing home, Cardiff, to Evelyn (*née* Wall Row), wife of Purser Davies, M C, M B, Ch B, of Newport, Mon.—a daughter

WAY.—On April 21st, at "Croyland," Finchley road, N W, to Phillis wife of C Berkeley Way, M C, M B, B S Lond, &c, late 50th Field Ambulance—a daughter

MARRIAGES.

FENWICK—GRAY.—On April 20th, at Airlie Bridge of Weir, Captain S Fenwick, M C, R A M C, to Marguerite Amelia, elder daughter of John Gray, Bridge of Weir

VANDERMIN—HART.—On April 17th, at St Mary Magdalene's Church, Enfield, Henry F Vandermin, M D B S Lond, to Gwendolen Mary, elder daughter of Mr and Mrs A H Hart, of Hillcrest, *Enfield*

DEATHS.

GILL.—On April 16th, suddenly, at Shaftesbury House Formby, near Liverpool, in his 42nd year, Eustace Stanley Hayes Gill, M B, Ch B Liverpool, the dearly loved husband of Edith Mary Gill, and the well beloved and only son of Dr and Mrs Stanley Gill

PARSONS.—On April 27th, at a nursing home in London P H Parsons, L R C P, L R C S Edin, L F P S Glasg, aged 47

SHERRARD.—On April 24th, at Lusted Hall, Tatsfield, Caesar Dudley Sherrard, M R C S, aged 67

THORNE.—On April 24th at Wood View, Dore, C A Thorne, M B E, L R C P, L R C S, J P, in his 63rd year

WOOD.—On April 24th, while studying at Genoa, Cecil Denyer Wood, M.B, M R C P, of Sleaford, in his 32nd year

N.B.—A fee of 7s 6d is charged for the insertion of Notices of Births, Marriages, and Deaths

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE 1, Wimpole-street, W.

MEETINGS OF SECTIONS

Tuesday, May 4th

SURGERY SUBSECTION OF ORTHOPÆDICS (Hon Secretaries—A S Blundell Bankart, R C Elmslie) at 5 30 P M

Annual General Meeting—Election of Officers and Council for 1920-1921

Cases (at 5 P M)

Mr Laming Evans Dislocation of the Hips, Knees, Ankles, and Radii

Mr C J Marshall Deformity of the Lower Limbs

Mr R C Elmslie Paralytic Dislocation of the Hips

Wednesday, May 5th

SURGERY (Hon Secretaries—Cyril A R Nitch, Herbert J Paterson) at 5 30 P M

Exhibition of Specimens (at 4.30 P M)

Annual General Meeting—Election of Officers and Council for 1920-1921

Exhibition and Demonstration of Specimens of Innocent Tumours of Alimentary Tract and Leather-bottle Stomach

Thursday, May 6th

A CONJOINT MEETING of the SECTION OF OBSTETRICS AND GYNÆCOLOGY WITH THE NORTH OF ENGLAND AND MIDLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETIES will be held

At 10 30 A.M Discussion on The Treatment of Antepartum Hæmorrhage, to be opened by Dr Hastings Tweedy

At 2 P M Annual General Meeting—Election of Officers and Council for 1920-1921, followed by—

Discussion on Rupture of the Cæsarean Section Scar in subsequent Pregnancy and Labour,' to be opened jointly by Dr Munro Kerr and Dr Eardley Holland Reports will be presented from various hospitals

At 7 30 P M Dinner at the Great Central Hotel Price of tickets, 10*s* 6*d* Mr J D Malcolm, President of the Section in the chair

It is earnestly hoped that Members of the Section will make a special effort to attend these meetings and the dinner

Will Members who wish to take part in the discussion or to be present at the dinner, *kindly send their names as soon as* possible to one of the Hon Secretaries (J S Fairbairn 42 Wimpole street, W 1, *Herbert* Williamson, 8, Queen Anne street, W. 1)

Friday, May 7th.

LARYNGOLOGY (Hon Secretaries—Irwin Moore, Charles W Hope) at 4 45 P M

Annual General Meeting—Election of Officers and Council for 1920-1921

Cases (at 4 P M) will be shown by—

Mr Dawson, Mr Layton, Dr Dan McKenzie, Dr Irwin Moore Mr Norman Patterson Mr Ryland, and others

Notes, Short Comments, and Answers to Correspondents.

THE CHINESE HOSPITAL IN FRANCE, 1917–1919.

BY C. FREDERICK STRANGE, M.R.C.S., F.R.G.S.,
CAPTAIN, R.A.M.C.; MÉDAILLE D'HONNEUR DES ÉPIDÉMIES.

IT is possible in this article to tell only part of the story of the First Chinese General Hospital in France, and of all the good work that was done there. When it was realised that the outcome of the Great War was going to be determined by man power, and that every Britisher available was wanted for the firing line, it was decided to form a corps recruited from Chinese voluntary labour for work on the lines of communication and at the ports. From small beginnings the corps rapidly assumed great dimensions, so that when the Armistice was signed there were approximately 130,000 Chinese labourers in France all on a three years' agreement. Noyelles was chosen as Chinese Depôt Headquarters and a large hospital built there for the sick and wounded. This was the main hospital, but there were smaller ones established in various centres such as Calais, Boulogne, Dieppe, Rouen, which acted as feeders to the one central base hospital, which was known originally as No. 1 Chinese General Hospital (to which I acted as surgical specialist), but afterwards as No. 3 Native Labour General Hospital. Commencing in the spring of 1917, while the battle of Arras was still raging, it grew rapidly in dimensions to a 2000-bedded hospital.

The greatest number of in-patients on any one day was 2600. When hostilities ceased there was not a better organised or better equipped hospital in France, and under the able command of Lieutenant-Colonel G. Douglas Gray, of the British Legation, Peking, there grew up large special departments to cope with the ever-increasing demands. These departments, each under the charge of specialists, included: surgical, medical, ophthalmic, mental, tuberculosis, leprosy, venereal, pathological and bacteriological. The hospital covered a very large area and, fortunately, had plenty of room to expand.

Speaking generally, there were no special diseases peculiar to the Chinese, but uncommon diseases such as leprosy, insanity, and tuberculosis with various unusual clinical manifestations, occurred. Diseases of the eyes necessitated special treatment to prevent their spread amongst British troops and the French population, with whom the Chinese mixed freely.

There was a peculiar and insistent belief prevalent amongst a large section of the British Army that there were many Chinese women amongst the labourers in the Chinese Labour Corps. But I gladly take this opportunity of denying this charge. There was not a single woman amongst them, though some of the Chinese labourers, either in facial appearance or in dress, appeared like women to the eyes of the untravelled Westerner.

Medical Examination.

The Corps was recruited from picked labourers, mostly from North China, where the climate resembles that of Northern France. All were submitted to a thorough medical examination at Wei-hai-wei or Shanghai before embarkation. Many thousands were rejected in China as unfit. After a long voyage round the world they ultimately arrived in France, and were immediately taken to the Headquarter Depôt, where they had to undergo another most thorough inspection by the medical officers of the hospital. Every recruit was examined by at least three doctors before he was passed as fit into a labour unit. This examination was undoubtedly very amusing to those who had the opportunity to witness it and who do not know the Oriental. The men were assembled in companies spread out in long lines on a wide field reserved for the purpose. They came along in single file to the doctor who examined first the throat, abdomen, and limbs; the throat and neck with special reference to mumps and tubercular glands; the abdomen with special reference to enlarged spleen and intestinal troubles; and the musculature of the arms and legs to detect any evidence of beri-beri or leprosy. When passed they ran away shouting for joy to another part of the field, where they were stripped behind screens and a thorough urino-genital examination was carried out for any evidence of syphilis or gonorrhœa. Thence they were conducted to another part of the field, where the eye specialists—always two or three in number—examined their eyes, especially for trachoma, which is very common amongst the Chinese. On the whole, the various shipments arrived in excellent health. Any found diseased were immediately admitted to hospital and not allowed to leave until cured.

"*The Old Disease*"

Amongst medical diseases tuberculosis was far the most rampant and destructive to life It was astonishing to note the rapidity with which men, apparently healthy on arrival in France, fell victims to this disease We had many special wards where all cases of tuberculosis were isolated, and, generally speaking, the only deaths which occurred in hospital were from phthisis or other forms of general tuberculosis The hospital cemetery at Noyelles bears testimony by the hundreds of white crosses to the ravages of this disease amongst the Chinese Almost every day there was at least one death from phthisis We had special wards for surgical tuberculosis so that this disease was isolated at once and everything done to prevent its spread The Chinese as a nation have suffered from pulmonary tuberculosis for many centuries past, so that it is now called by them by the significant title 'The Old Disease" Major Graham Aspland made a very efficient officer in charge of the Medical Division, and when he went to China in charge of a hospital ship full of the sick and afflicted his place was efficiently taken by Captain E J Peill

Lunacy

I cannot explain why so many Chinese went mad in France Our mental hospital was very well organised indeed and came in for universal praise from visitors Frequently there were over a hundred insane Chinese housed in it Captain H L Fearn, of Shanghai, made an excellent officer in charge He lived in the same compound with the insane and slept on the same premises within barbed wire Very rarely a lunatic escaped One religious maniac managed to do so He was always wanting everybody to baptise him, and he got upon the top of the hut one day in search of someone for this purpose and fell off, breaking his right tibia and fibula He was admitted to one of my surgical wards and I successfully plated his tibia, but he had to be shackled to the bed all the time he was in my ward When healed, he returned to the mental compound, but took the first opportunity to escape How he managed the barbed wire no one knows, but he was found at 5 A M , at a height of 20 feet, on the top of the water tank—the main hospital supply—trying to defile the water He resisted all efforts to get him down, a free fight ensued, and he fell, again grazing the old broken leg from knee to ankle, but his leg stood the strain well and it made no difference to the plate Another lunatic pierced his abdomen 14 times with a pointed steel file, bending the tip of it against his lumbar vertebræ in his determined efforts to kill himself However, all the 14 wounds in his intestines were sutured, and he made a good recovery But he developed maniacal symptoms again, and was readmitted to the mental block We were sorry at the relapse, because he was skilled at wood carving, and did some exquisite work

Leprosy, Venereal Disease, Influenza

As the war went on leprosy began to manifest itself amongst the Chinese So we had to establish a small leper colony, of which there were a dozen inmates when the Armistice was signed All symptoms of leprosy developed after arrival in France, and the disease was usually observed by M O s who had been familiar with it in China

Our venereal wards were always full and an amazing amount of salvarsan and mercury had to be used

During the influenza epidemic which caused so much havoc amongst European troops, the Chinese were not great sufferers We had special wards for influenza cases It ran very much the same course as amongst the soldiers with the same clinical manifestations We were lucky in having a comparatively small mortality list

Ophthalmic and Surgical Cases

Perhaps the most widely known medical work amongst the Chinese was in connexion with the ophthalmic department Trachoma is a disease very common in North China, and every precaution was taken to prevent its spread in France Every Chinese Labour Corps unit from Calais to Verdun was regularly inspected by our eye specialists This involved an enormous amount of travelling and incessant work The ophthalmic wards were separated by a road from the general hospital, and all these unhappy sufferers were rigidly isolated, one part under canvas for ordinary conjunctivitis, and other wards for trachoma When well enough to work the latter were formed into special trachoma companies, and were not allowed to mix with other labourers At their special depôts they were under constant medical supervision, and were provided with all facilities for carrying out the special treatment for this disease

The surgical cases were many and varied The surgical specialist was much envied by visitors to the hospital, who were invariably surprised at the number, variety, and interest of the surgical cases, and expressed unreservedly their appreciation of the excellence of the surgical work There were six surgical wards of 50 beds each and these were always full This being the "Blighty" base hospital for the Chinese we had a remarkable lot of clean surgical work, as well as a fair share of those wounded by bombs, shells aerial torpedoes, explosions, and accidents

Hospital Nursing

The nursing in the hospital was done entirely by Chinese male nurses and dressers, who had had a certain amount of hospital training in mission hospitals in China and who were brought over from China for this special duty ' There was never a large enough supply of English nurses in France to spare any for the Chinese Hospital and yet the cleanliness of the wards and the good nursing were the subjects of frequent comments by visiting sisters and nurses The hospital garden provided an ample supply of vegetables, and we took seven prizes at the British Exhibition of Agriculture at Abbeville in 1918 The splendid discipline displayed and the fact that Chinese speaking medical officers, who knew and understood the Chinaman, were gathered together for duty at this hospital reflects the greatest credit upon the O C , Lieutenant Colonel G Douglas Gray

Politically it was of the greatest importance that we did well for these 130 000 Chinese in France, for each one passed through the hospital at least twice, if not oftener and their good report may help to cement Anglo Chinese friendship in a country growing in importance every day I would conclude by pointing out what splendid scope there is for British medical education in China to day It ought to be seized by us before any other nation gets in, as the Germans did in Japan, and robs us of a great opportunity

---

MOTHER STAYS AT HOME

WE appeal constantly to our readers to help to get for children a temporary sojourn in the country, and in no way can money be better spent than in improvement of health and provision of pleasure With the latter object only in view subscriptions are collected by numberless kindly organisations to provide days in the fields for children The mothers of these children are grateful alike for the happiness of their offspring and for the day's rest which they obtain from the endless moil of poor parenthood But when the strain on the working class mother is recognised—and to medical men it is a familiar circumstance—it is impossible not to see that it is often the mother rather than the child that is in need of the change of air and environment The situation of such a mother was brought home at the Æolian Hall last week, where a mixed programme of vocal and instrumental music and recitation was given by Miss M Foster, Miss M K Snowden and Miss Louise Perceval Clark One of Miss Perceval Clark's recitations set out pathetically, but without mawkishness, the intense longing for the country which may fall upon a mother when thinking of and rejoicing in the delight of one of her children who was starting for a day in the country This situation cannot be wholly met, because while the children can go into the country without their mothers, the mothers cannot go into the country without the children We commend to Miss Perceval Clark who herself writes what she recites, the remedy for this dilemma as a subject for a recitation The continued physical and nervous strain to which the poor mother is subjected is a matter the importance of which has long been clear to the medical profession

BRISTOL BOARD OF GUARDIANS AND A CONSULTING MEDICAL STAFF

THE Bristol board of guardians is advertising for a visiting consultant staff for the Southmead Infirmary, shortly to be opened A medical and surgical specialist will be appointed each at a salary of £100 per annum, also a physician for diseases of children (£50 a year) and another with special qualifications for ear throat, and nose diseases The terms offered to the latter, as also to a dental surgeon, are a retaining fee of £5 per annum and a fee per visit to be arranged later

LIFE IN JAMAICA

To the Editor of THE LANCET

SIR,—As a recent visitor to Jamaica I would strongly advise any medical man who contemplates sending patients there to make careful inquiries before doing so To me it seems that it is no place for an invalid at the present time By the direct route, which is to be avoided the voyage, generally unpleasant in winter, may take from 14 to 23 days, but on arrival at Kingston the traveller may find that there are no rooms to be had, and may have to return in the boat he went out in If he has gone to the expense of engaging rooms by cable he may be told at the hotel that in spite of their cabled promise no rooms have been reserved for him The hotels are for the most part primitive It was stated in a daily paper last winter that prices in Jamaica were low and living cheap Things seem to have changed, for they are nothing of the kind The visitor must make up his mind to rough it and pay heavily for the privilege

I am, Sir, yours faithfully,

Norfolk street, W 1, April 26th, 1920 H G WHARRY

PUBLIC HEALTH IN BRITISH GUIANA, 1918.

THE year 1918 was an unhealthy one in British Guiana, owing to influenza, malaria, and other causes. The total death-rate was 40·6 per 1000, a considerably higher ratio than in any previous year since 1868; the birth-rate, 25·1, was lower than in any year since 1894. The chief cause of increased mortality was the invasion of influenza which appeared in a mild form and over a restricted area in July and August, and again as a widespread epidemic of severe type throughout the colony in November and December. Surgeon-General J. H. Conyers, who presents the report, states that "it is not possible to give the actual deaths from influenza, for many were uncertified, and many certified as pneumonia and bronchitis were probably due to influenza." It is stated in paragraph 183 that the registration district of Mara suffered most "with the extraordinary mortality of 778 per mille." This would certainly be an extraordinary mortality; but there is some mistake, as the deaths from all causes in this district numbered 119 in a population of 3501 (34·0 per 1000), as stated in Table 23. On the Mara sugar estate 112 deaths occurred during January in a population of 539—that is, 207·8 per 1000 for the month.

Enteric fever prevailed in Georgetown and the district of Peter's Hall, as in the previous year. Typhoid and paratyphoid vaccine was supplied by the Bacteriological Department and distributed extensively (20,275 doses in 1917 and 10,372 doses in 1918 for the whole colony), with good results. Ankylostomiasis is being controlled by the erection of latrines and the treatment of all persons found to be infected. There was an increase in malaria (1680 deaths), the ratio (54 per 1000) being higher than in any year since 1911. In the report for 1917 it had been stated that—

> "A special malarial gang is absolutely necessary, constantly at work under the control of one who has had special experience and training in this work in this colony. If these gangs are supplied it would be easy to reduce the malaria deaths and sickness in any community, estates as well as villages, by a third and probably in a few years by two-thirds or three-quarters. This is the proper and only cheap method of preventing this terrible disease. ...... Quinine can never take the place of permanent and thorough drainage, with careful and constant attention to unavoidable water collections."

This is undeniable, and has been an ascertained fact for many years past. At the same time, quinine administered prophylactically has a distinct value. It was found that on the sugar estates, "where more care is taken in the drainage of the 'yards' and quinine is given more regularly, the malaria-rate is much lower than in the adjacent villages."

"CHASTITY BY TERRORISATION."

THE suggestions for the control of venereal disease, issued by the Medical Women's Federation,[1] were printed in full in the *Guy's Hospital Gazette* for Feb. 21st. In the succeeding number of the same journal there appears a spirited criticism of some of these suggestions over the initials "G. H. F. G.," who quotes a sentence in which the fear is expressed that from the use of prophylaxis "a phase of society would be produced as vicious and degenerate as any of which history has record. ...... Moral degeneration and sex excesses would rot the very foundation of society." What were the foundations of society doing, asks "G. H. F. G." before 1493, when syphilis was introduced into Europe? And in rural Ireland, where venereal disease is unknown, do we find a phase of society as vicious and degenerate as any of which history has record? He finds in their arguments a "policy of chastity by terrorisation," and claims that no real moral advance can be made along such lines. As regards the practical efficacy of prophylaxis, the writer quotes the experience of a flotilla in the Eastern Mediterranean, in which the method was strikingly successful. He points out that the men had every incentive to preserve themselves from infection—an important condition, and one not always obtained in the army.

For our part we do not find "G. H. F. G.'s" comparison of two different epochs very helpful. The greater freedom of action now enjoyed by girls of the enormous middle-class, which did not then even exist, and the increased knowledge of methods to prevent conception, have altered social life to an extent which makes the comparison futile. The real difference between the two standpoints rests on opposing premises. "G. H. F. G." interprets certain evidence as a proof that properly organised packet systems are efficacious, whereas the Women's Federation pin their faith to statements from equally reliable authorities asserting the reverse. The Federation expressly disclaims the view attributed to them—namely, the advocacy of retaining disease as a deterrent from promiscuous indulgence. Their point is rather that the official issue of packets would encourage a false sense of security, leading to increased indulgence, and therefore to increased disease. The problem of whether the use of prophylactic packets, if proved effective, is to be condemned has apparently not been considered by the Federation of Medical Women.

THE MATRIARCHAL FAMILY IN FRANCE.

THE grave question of depopulation in France that has already been frequently discussed in the French medical press, and was the subject of an annotation in THE LANCET of April 3rd (p. 779), is taken up again by Dr. Paul Carnot in the *Paris Médical* of April 17th. After pointing out that in 20 years' time the French race will be swept out of existence if French women do not make what he calls a superhuman effort of maternity, M. Carnot very frankly states the actual conditions and their possible remedy. There are now in France 2,000,000 unmarried women capable of bearing children and deprived of husbands by the war. To take the place of the men who have been killed there are two alternatives: (1) to marry French women to foreigners—a solution that seems to M. Carnot very dubious, and one which has had, so far, no encouragement from the authorities, although it is the only way in which it is possible to secure legal husbands for French women; (2) to permit polygamy during a certain period—a solution that no one wants, and which would be probably useless, as men already find it difficult enough to support one woman, and restrict their families on that account.

Before suggesting the only alternative he sees, M. Carnot quotes some Danish statistics to prove that in Europe there are now 15,000,000 more women than men, a figure that he thinks shows the necessity for a matriarcal family composed only of mothers and children, of which he reminds his readers that many civilisations have given examples. This matriarchal family would only be possible if it were State-supported, and basing his argument on the fact that the supreme law of a race is not to perish, M. Carnot strengthens his defence by the axiom that in a well-organised society maternity ought to be a woman's career, since, socially speaking, every woman ought to become a mother. This career for women has never been properly organised, but should be both honoured and recompensed, and the day when maternity is made a remunerative career many women will have children who now hesitate before the expense of bringing them up, and the uncertainty of the future.

Finally, M. Carnot believes that if it were not for the opposition of public opinion many women would be glad to satisfy their maternal instinct and become the mothers of children, who would be their companions in old age. If this be true the question is largely one of public opinion and economics. Before asking a woman to bear children her future and theirs must be assured by the State. To provide funds the people who have not fulfilled their social duties to the State should be obliged to leave their money to support the children of those who have.

PLURAL BIRTHS IN THREE GENERATIONS.

To the Editor of THE LANCET.

SIR,—On April 16th I attended Mrs. E. P. in her confinement with twins. Her sister in three confinements had twins each time. Her mother had triplets and her grandmother also. It is not often, I think, that twins and triplets occur in three generations.

I am, Sir, yours faithfully,

Bristol, April 20th, 1920. THEODORE MARTIN.

HOME HELPS.

To the Editor of THE LANCET.

SIR,—I read with interest your annotation in THE LANCET of April 10th on this subject. We have established here a service of home helps, although the difficulty in obtaining satisfactory women is very great. It must, I think, be admitted that the home help who would satisfy every mother to whose house she is sent would, indeed, be a very extraordinary person. We have temporary home helps who are paid 3*s.* a day and their food when they are acting for us. From the ranks of these the most satisfactory are sent for a course of training to a hostel for illegitimate babies. They stay there six weeks and we pay for their maintenance whilst they are being trained. Before they are sent for training they sign an undertaking to remain in our service for 12 months after its completion. They are then taken on the permanent staff and are paid 3*s.* a day with food when employed as home helps, and 1*s.* 6*d.* a day on the rare occasions when we have no work for them. During this period they can obtain other work should they desire, subject to their responding to a call within 12 hours. The mothers, to whose homes they are sent, make a contribution towards the cost, in many cases paying it all, and most of them are very grateful indeed for the assistance which we can render to them.

I am, Sir, yours faithfully,

W. ALLEN DALEY,

April 19th, 1920. Medical Officer of Health, Borough of Bootle.

W. H. K.—The admirable suggestion is in harmony with all that we have been saying for years past.

A Lecture

ON

THE SURGICAL TREATMENT OF PROLAPSE OF THE UTERUS AND VAGINA.

Delivered at the Royal Society of Medicine on May 5th, 1920,

BY W BLAIR BELL, B S, M D. LOND, &C,
GYNÆCOLOGICAL SURGEON TO THE ROYAL INFIRMARY, AND LECTURER ON CLINICAL GYNÆCOLOGY IN THE UNIVERSITY, LIVERPOOL

INTRODUCTION

IT is somewhat surprising that, when so much is being said and written about the care of the pregnant women and the safe conduct of parturition, so little attention has been directed at the same time—publicly, at any rate—to the prophylaxis and treatment of prolapse, a gynæcological condition which is almost invariably a sequel of parturition, and which is so common that Fothergill has stated that "plastic vaginal work thus forms, roughly, a fourth part of the whole operative work done" (at St Mary's Hospital, Manchester) Moreover, the condition is so disabling that a large proportion of those women who suffer with prolapse of the uterus and vagina are physically incapable of performing their household duties Yet the subject has not been neglected by gynæcologists, many of whom have gone down to posterity with their names appended to pessaries, indeed, at the present time there is probably no subject in gynæcological surgery to which gynæcologists have given more consideration than to the surgical treatment of prolapse. I shall not attempt to dogmatise, as so many have done, for I hope to show that the question is one that requires the exercise of judgment, and that the constantly recurring assertion, "the one and only way to cure prolapse," should represent at best only a method of choice in certain given circumstances It is the attitude, adopted by so many who assert that some particular method as practised by them is the best, the only, way to cure prolapse, that has led to the diversity of opinions and methods now set forth, and, I regret to add, to the disappointment of many a patient

The fact that a number of cases on which I have myself operated had previously been subjected—once, twice, up to five times—to the procedures advocated by the surgeons performing the operations, makes me feel somewhat reticent about the methods I practise perhaps some may know of failures of mine In this case, I hope to be informed, that I may benefit by the experience, if I have not already done so We learn only by our failures, and, lacking these, by the failures of others. Having said this, I hope I may be forgiven for illustrating (Figs 1 and 2) two of many of the post operative failures that have come under my notice I may say that the operators concerned are gynæcologists of repute who are interested in the subject, and that the cases illustrated have come under my care during the last two years—facts which will, I think, lend force to my statements, and prove convincingly that neither in opinion nor practice have we reached finality.

Nevertheless, whatever real (I shall explain what I mean by "real" later) failures there may be following my own operations—and, unfortunately, perhaps, I do not known of any—and the procedures of others, I believe that to day it is possible practically to guarantee the cure of any prolapse whatsoever, not by one method, but rather by the method or combination of methods suitable to each particular case I do not deny, however, that many cases can be cured by almost any method, and it is this very fact that blinds those who are satisfied with less than 99 per cent of cures

I am only concerned here with the surgical treatment of prolapse of the uterus and vagina, but it goes without saying that much can be accomplished in the way of prophylaxis, and that all surgical procedures are based on a correct appreciation of the normal anatomical conditions and on the lesions present in prolapse The operations practised should aim at a correction of the lesion or lesions, or at the best possible compromise; and as the lesions vary with a corresponding variation in the clinical picture, the procedures must vary accordingly Hence, it is that no one operation meets all the requirements in regard to surgical treatment of every case

The total number of cases of prolapse on which I have operated is not large, approximately 400 in all, with (so far as I know the cases are being investigated at present) 99 per cent of cures, and a mortality of 2, or 0 5 per cent The operative treatment adopted was only indirectly concerned with these two deaths, as I shall show presently

CLINICAL TYPES OF PROLAPSE.

The following states, which may be encountered in varying degrees of severity, present themselves for consideration —

A. So called "congenital" prolapse

B Puerperal retroversion and flexion, with slight actual, or with potential, descent

C. Vaginal prolapse

D. Prolapse of the uterus and vagina (1) during the reproductive period, (2) after the reproductive period

In discussing the procedures which, in my opinion, should be practised in the different states recorded above, I shall describe my present practice which has naturally been more or less gradually evolved, although long ago it had reached a state of comparative stability.

"Congenital" Prolapse

It must be mentioned that what is usually called ' congenital" prolapse is not the condition sometimes seen in infants with spina bifida, but the prolapse that occurs soon after puberty, and is no doubt primarily due to inherent defects in the pelvic floor I think there can be no doubt that this condition in its advanced stage is usually considered to be the most difficult of all forms of prolapse to treat effectually It is not common and must of course be distinguished from congenital hypertrophy of the vaginal cervix I have only treated some half dozen cases of these so called "congenital" prolapses Two of the cases on which I have operated had previously been submitted to operation One had had colporrhaphies and perineorrhaphies performed on two occasions, and the other case had actually undergone five operations, four times plastic vaginal work had been done, and last of all ventrisuspension (peritoneal adhesion) had been tried

In Fig 1 the result of these five operations a few months later is shown I had this photograph taken simply and solely because the surgeon who had performed these five operations has very strong opinions about the cure of prolapse Moreover, it is instructive, in that it shows plainly—as did the other case of a similar nature—that no surgeon, however skilful with his particular methods of plastic work on the vagina he may be, can cure these cases of congenital procidentia by such work alone nor will superadded ventrisuspension help in the cure This patient has now been cured at one sitting by what I consider to be the correct procedures First, effective plastic work on the vagina was performed, together with amputation of the cervix Next, the abdomen was opened and a string like band some 6 inches in length, representing the remains of the peritoneal fixation, was excised The posterior segment of the peritoneal aspect of the pelvic floor was then reconstructed—an essential procedure—and the uterus was suspended by means of a modified Gilliam's operation The result has been perfect.

I shall deal with the technique of all these procedures later

In the other case, on which two vaginal operations had been performed on two occasions by another gynæcologist, I was able to cure at one sitting the "congenital" procidentia by almost similar procedures, and, when examined recently, after an interval of 12 years the result was found to be so good that it would be impossible if it were not for the slight laparotomy scar, for anyone to know that an operation had been performed, or that the woman had ever been other than normal She has never married, so the test of child bearing has not occurred

Puerperal Retroflexion

I believe that puerperal retroflexion is in the first stage of a large majority of all cases of acquired prolapse of the uterus, and should be treated as such In those cases in which the vagina is not stretched or torn a timely operation to cure the condition will save much operative work in the future. I have described elsewhere[1] the non-operative treatment of those cases of puerperal retroversion that are discovered during the puerperium. Unfortunately they are frequently overlooked, and at a later date operative treatment alone will effect a cure. If there be vaginal laceration this, of course, must receive attention; but when the retroflexion is the only important lesion—and it may be associated, when discovered, with slight descent—it is sufficient to perform a modified Gilliam's operation alone. I find I have carried out this procedure 135 times in this class of case with excellent results and no mortality. It must be remembered, nevertheless, that in subsequent labours vaginal laceration may occur and necessitate further operative treatment; but, provided this is not too long delayed and a vaginal prolapse has not stretched the supravaginal cervix, the uterus will always, no matter how many may be the subsequent labours, maintain the good position that results from a properly performed modified Gilliam's operation.

Vaginal Prolapse.

As has been so well emphasised by Fothergill, but overlooked by many, it is possible to have vaginal prolapse in association with a normally-placed uterus. In most cases the vaginal prolapse is represented by a large cystocele, more rarely by a rectocele, and still more rarely by a cystocele and rectocele. It must not be forgotten, however, that it is practically impossible for a vaginal prolapse to exist indefinitely without the supravaginal cervix being stretched, and prolapse of the uterus being produced, unless there be pelvic infection or some other pathological cause preventing the descent of the vaginal fornices.

If there be prolapse of the vagina alone, it is obvious that only plastic operations on the vagina will be required.

I find that I have carried out vaginal repair alone only in 16 cases; and, as in over half of these cases operations, including Gilliam's operation and ventrifixation, had been previously performed by other surgeons, and as in three it was necessary to perform vaginal hysterectomy, it will be seen there were but few uncomplicated cases in which I considered vaginal repair alone to be justifiable. Moreover, in 20 other cases vaginal repair was associated with laparotomy for the treatment of other lesions, such as fibromyomata of the uterus and pelvic infections.

It will be obvious from these statements how rarely I have felt justified in resorting to colporrhaphies and perineorrhaphies alone, in order to cure prolapse; in other words, how comparatively rare is purely vaginal prolapse. Yet, the Manchester School asserts that it is possible to cure every case of prolapse by means of plastic vaginal work. As I shall demonstrate directly, my method of plastic vaginal work is probably more efficient than the usual procedures practised, but I am certain that it is impossible to obtain good results by vaginal plastic work alone, however good, in bad cases of prolapse. Moreover, even if one had not the evidence of facts, such contradictory statements as the following would shake one's faith in the methods advocated: "If the patient were to come back a year after operation (that is, after plastic vaginal work) with a retroverted uterus, backache, pain in the side, or dyspareunia due to prolapsed ovaries, it would no doubt be proper to open the abdomen and sling the uterus in anteversion by a Webster's or a Gilliam's operation. But this would be operating for retroversion, not for prolapse"[2]; and, in discussing "Classical Prolapse. Prolapsus Uteri, Stage 1," a few pages earlier: "Thus, when the patient strains there is not only cystocele, but also retroversion."[3] Readers must draw their own conclusions; but it seems to me that if retroversion be stated to be, as indeed it is, present as a feature in the first stage of uterine prolapse, the other statement which I have quoted above regarding treatment is more than illogical. However, to come down once more to facts: Fig. 2 is a photograph of a patient who had "classical prolapse"—procidentia. Twice plastic operations on the vagina were carried out, and last of all ventrifixation had been performed. This patient is now under treatment, and I hope she will be cured.

Nevertheless, as already stated, vaginal prolapse alone with an anteflexed uterus may occur, but it is rarer than might be supposed, because the ultimate result of vaginal prolapse is to produce uterine prolapse. When, however, the patient is seen with vaginal prolapse alone—cystocele or rectocele or both together—then properly performed plastic vaginal work is all that is required to effect a cure.

Prolapse of the Uterus and Vagina.

This state may exist in all degrees; there may be slight descent of both uterus and vagina; the vagina may be badly prolapsed and the uterus but slightly; the uterus may be much prolapsed and the vagina but a little; or the uterus and vagina may be completely prolapsed—procidentia. Now the treatment of these conditions—and we may include the so-called "congenital" prolapse to which reference has already been made, for the treatment is much the same—would be easy and hardly worth discussing if vaginal plastic work was all that was necessary to effect a cure. I have shown two instances out of not a few that have come under my care, in which plastic work on the vagina performed by two different operators failed to cure, and in which even the last resort of a baffled mind—ventrifixation—also failed to relieve in either case.

I have performed this combination of vaginal repair with ventrifixation myself—once, and once only—and that many years ago. I believe the result in that case was satisfactory, but even then I was not convinced that it was the right treatment. It was one of those cases that almost any method will cure. The evidence of some 20 to 30 cases in which I have operated after others had performed ventrifixation has convinced me that, allowing for perfect technique on the part of the operator, the operation is a thoroughly bad one. I have discovered bands many inches in length and of the same thickness as that of string; I have found a uterus free and completely prolapsed, with no adhesions at all; I have had to perform vaginal hysterectomy, and in two cases during the procedure to dig a uterus firmly adherent to the anterior abdominal parietes out of a mass of intestinal adhesions. In one of these cases the uterus measured internally no less than 6½ inches. The cervix presented at the vaginal orifice and the vagina was badly prolapsed. Fig. 3 is a photograph of this interesting specimen. This patient, I am sorry to say, died of peritonitis, probably owing to some bowel being partially stripped of its muscular coat during the separation of the adhesions. But this death must really be attributed to the imperfect procedures previously practised—procedures which not only failed to relieve the patient of the condition from which she was suffering, but even caused serious intestinal complications.

What operations, then, should be performed in these cases? It seems to me that there are really only two classes into which we can divide cases of prolapse of the uterus and vagina in regard to surgical treatment: (*a*) prolapse during the reproductive period; (*b*) prolapse after or about the menopause.

Prolapse of the Vagina and Uterus Before the Menopause.

In prolapse of the vagina and uterus before the menopause, and included in this category are the cases of so-called "congenital" prolapse, we must perform procedures compatible with subsequent parturition. Any operation that is incompatible must be ruled out of court.

For this reason the "interposition" operation, to be mentioned directly, must not be performed during the ordinary reproductive period; nor should ventrifixation be a procedure practised, as many difficulties and accidents have occurred during parturition after this operation. In connexion with this procedure it may be instructive to record the case of a young lady who consulted me a few months ago. She had been subjected to operation by a gynæcologist who had indulged in some ineffective plastic operation on the vagina and performed ventrifixation. He then told her that, owing to this operation, she must never become pregnant again, but in spite of this warning she conceived. It seems hardly credible that, on being consulted about the matter, the surgeon advised, and carried out, evacuation of the uterus! Such a case requires no comment, but I feel I should be lacking in scientific duty if I were to suppress such facts.

Peritoneal ventrisuspension is a useless operation; either the adhesion disappears or a long, narrow, dangerous band is produced, which, of course, is of no use for supporting the uterus subsequently.

What, then, can we do with safety and efficiency for the cases in question? We must repair the vagina and perineum, amputate or repair the vaginal cervix if necessary, and suspend the uterus by a modified Gilliam's operation. In bad prolapse—procidentia and especially in so-called "congenital" prolapse—we must also repair, or, rather, reconstruct, the peritoneal aspect of the posterior segment of the floor of the pelvis. I have performed 178 such combined operations with one death, due to a gauze pack, which I then used, being left by mistake in the vagina for ten days by the sister in charge. The patient eventually died of sepsis.

It is, of course, possible that the repaired vagina and perineum may suffer injury in subsequent confinements, but this is by no means invariable. I remember one woman, well under 30 years of age, on whom I operated for procidentia following her first confinement. Subsequently she had six children. She was confined in hospital with the first two following the operation, and she suffered no damage. Other confinements took place in her home, and when she came to see me about a year ago she was pregnant, and there was appreciable bulging of the vagina, with laceration of the perineum. She then had a difficult labour, and one of my colleagues delivered her—a very small woman—of a child weighing over 11 lb. with forceps. She was rather badly torn. After a few months I repaired the vagina and perineum. The uterus was still in a normal position.

---

[3] Fothergill, W. E.: New System of Gynæcology, 1917, ii., 628.

One cannot, of course, look upon such a case as a failure. The original procedure cured her, and, indeed, survived the test of subsequent labours. But, as in a first confinement the vagina and perineum may be torn, so also may an effective vaginal repair suffer damage in subsequent labours. Such cases cannot be considered operative failures. In the cases I have illustrated in this paper, and in those which I have *considered* failures when they have come under observation after having previously had operations performed upon them, no conception had occurred subsequently to the operation that had not proved successful.

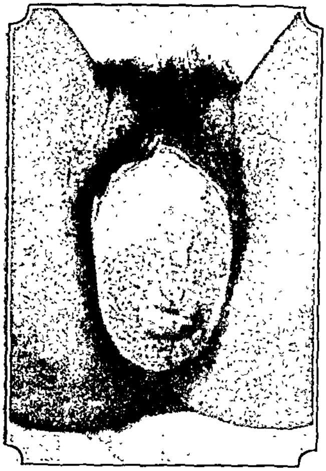

FIG. 1.—Complete procidentia in a case of "congenital" prolapse, subsequently to five operations. A scar can be seen on the anterior vaginal wall.

Prolapse of Vagina and Uterus at or after the Menopause.

In patients past the reproductive period—and by that I mean in women who have passed the menopause or who, having had children many years previously, are within a few years of the menopause—one is not limited by considerations of subsequent pregnancy. In these circumstances I seldom now open the abdomen. A majority of the cases are bad ones—that is to say, procidentia is often seen and the vagina may be ulcerated. After suitable preparation, if there is *no* descent of the uterus, vaginal repair alone, as we have seen, may be carried out; but when there is *any* degree of descent, and especially in the presence of a cystocele—*extremely common in* this class of case—I believe there is no operation to compare with the interposition operation, together with properly performed colporrhaphies, anterior and posterior, and perineorrhaphy.

In a few exceptional cases—I have one under my care at the moment, not included in my figures—it may be necessary also to open the *abdomen to reconstruct* the posterior segment floor of the pelvis from above.

I have performed the interposition operation with colporrhaphies and perineorrhaphies 42 times up to the date at which my figures have been collected. I have had no deaths or untoward symptoms, except in one case, in which frequency of micturition was caused by *insufficient separation of the bladder*—a state of affairs which was subsequently easily rectified through a laparotomy incision.

Surely, if there were any inherent and unavoidable reason why these *operations* for interposition of the uterus should eventuate in such terrible results as have been depicted, I could not have failed to have encountered it in some fifty or more experiences. My cases have almost invariably made a smooth recovery. In only three has there been any trouble, and in two this was in connexion with the perineum, and was of quite a minor character; in the other, in which the patient was found to have a recently-contracted *gonorrhœal infection of the tubes—a lesion dealt with at the operation—there was a somewhat* purulent vaginal discharge; this, however, did not interfere with the perfect operation-result obtained.

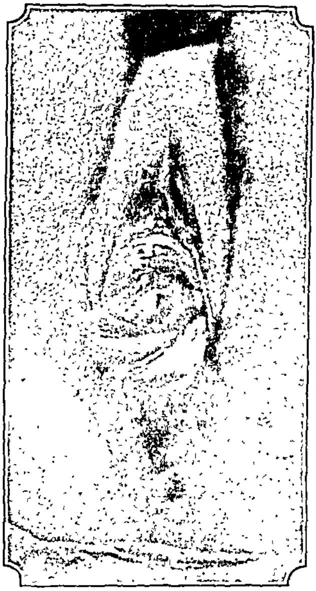

FIG. 2.—Prolapse of the uterus and vagina *subsequent to three operations.*

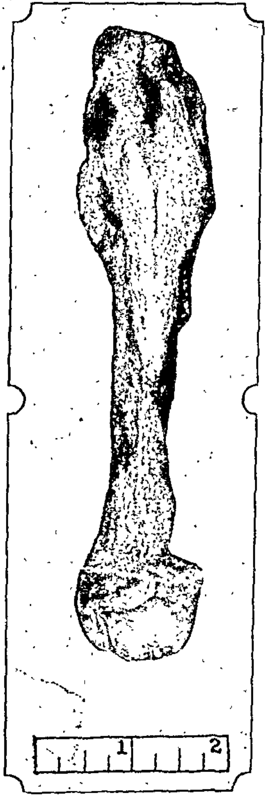

FIG. 3.—Greatly elongated uterus in case of prolapse subsequently to fixation and vaginal repair.

Schauta, to whom the introduction of this operation is attributed, lost five cases in 89 operations, and in 13 cases there were recurrences. Fothergill,[4] *commenting on these* figures, justly remarks that "no results could be much worse than these." Bissell has reported an almost incredible mor*tality of 75 per* cent., while Vineburg[5] states that "I abandoned it (interposition operation) myself on account of the extensive suppuration usually accompanying it."

Such a record is undoubtedly appalling, but so was the record of the first ovariotomies. The awful results reported in *regard to the interposition operation* have been due to the same cause as that which threw such a lurid light on the early ovariotomies—sepsis!

Of course, if simple plastic work on the vagina cured all cases of prolapse *there* would be no need to do more. But I firmly deny that it does so, and I have *adduced pictorial evidence in support of* my denial—evidence to which I can add if necessary. I know that such *measures* are ineffective except in the instances specified, even in the hands of *those* who advocate them. This being the case, what is to be done? I maintain that the interposition operation, if it can be done safely and *effectually—as it can—in conjunction* with colporrhaphies and perineorrhaphies, should be the method of choice after the *menopause.* Fifty deaths and no recurrences with smooth recoveries and perfect ultimate *comfort* to the patient is convincing to me. But, of course, if it cannot be done safely, *it should not be attempted.*

OPERATIVE PROCEDURES FOR PROLAPSE.

Abdominal Operations.

With regard to the operative procedures for the cure of prolapse we have seen that when there is a puerperal *retroflexion of the* uterus with slight or potential descent, but without vaginal laceration, a *properly* performed modified Gilliam's operation meets the case; indeed, the operation *must* in these circumstances be regarded as valuable prophylactic treatment against further prolapse, apart from the relief afforded to the symptoms connected with the condition so treated.

[5] *Vineburg, H. N., Amer. Journ. Obstet.* and Gynecol., 1919, lxxix., 677.

Modified Gilliam's operation.—I have described my modification of this operation, and have illustrated the different steps of the procedure in the third edition of my Principles of Gynæcology. This is, in my opinion, the only satisfactory method of suspension of the uterus, whether it be practised alone or in conjunction with plastic work on the vagina. I think the chief reasons why it is so satisfactory are that it is mechanically efficient, and that if pregnancy occurs subsequently the round ligaments hypertrophy, as always in this physiological state, and undergo involution afterwards. This sequence of events is, of course, in great contrast with what occurs after peritoneal ventrisuspension and ventrifixation in connexion with subsequent pregnancy. Apart from the other disadvantages of these two methods, pregnancy in the first case leads to stretching of the peritoneal adhesion, which is subsequently useless so far as support of the uterus is concerned, while ventrifixation prevents the proper development of the pregnant uterus and is a danger in parturition.

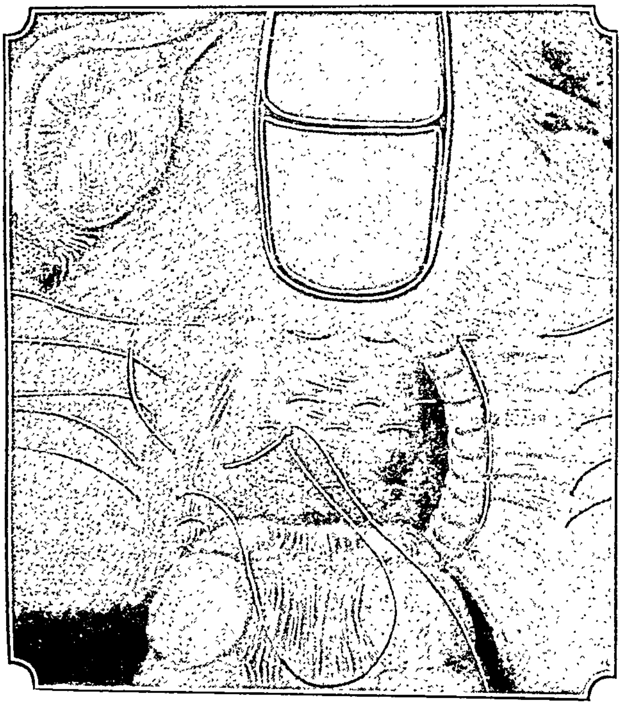

FIG. 4.—Early stages of author's method of reconstructing posterior segment of pelvic floor.

Reconstruction of posterior segment of pelvic floor.—The other intra-abdominal procedure for the relief of prolapse that I have mentioned is the reconstruction of the posterior segment of the peritoneal aspect of the pelvic floor.

For some time I contented myself with reconstruction of the utero-sacral ligaments. These so-called ligaments contain involuntary muscle-fibres which, like those of the round ligaments, are directly continuous with the external muscle-coat of the uterus; they form, too, the posterior part of the antero-posterior sling of muscle-fibres attached to the back and front of the supravaginal cervix, which stretches from the sacrum to the symphysis, being continued in front of the uterus between the base of the bladder and the anterior vaginal walls. We shall see directly that the anterior portion must also receive attention from the operator in cases of prolapse. I have depicted in my work on Gynæcology, just mentioned, a method which I have employed in the reconstruction of the utero-sacral ligaments. It will be seen at once how great is the support that such reconstruction gives to the uterus, and that there is retraction of the cervix, into the posterior segment of the pelvis. I was led to undertake reconstruction of the utero-sacral ligaments because I found that even after vaginal repair and the suspension of the uterus by means of a modified Gilliam's operation, the patient, when the prolapse had been a bad one, subsequently suffered with bladder irritability owing to the cervix swinging forward and nipping, as it were, the bladder between the uterus and the back of the symphysis. I rarely practise simple reconstruction of the utero-sacral ligaments now, for although the cervix is kept back by this procedure, there is still left a deep pouch—the pouch of Douglas—which forms a hernia sac in these circumstances. I look upon any success I may have had in the cure of "congenital" procidentia as largely due to the obliteration of the enormously deep and extensive pouch of Douglas present in these cases, together with reconstruction of the utero-sacral ligaments and the other procedures employed in conjunction with the reconstruction of the posterior segment of the pelvic floor. The obliteration of the pouch of Douglas is effected with silk sutures which run in and out through the peritoneum transversely across the pouch of Douglas and pass behind the reconstructed utero-sacral ligaments to terminate on either side above them (Fig. 4). The ends are subsequently tied, so as to bring the utero-sacral ligaments together in the middle line (Fig. 5). In this way a solid floor is made running from the base of the broad ligaments on either side across the back of the cervix and around the sacral arch, leaving room only for the rectum to pass through. The rectum should be fixed with one or two sutures to the edges of the aperture in this new part of the pelvic floor through which it passes. Anyone who has not seen and actually felt the wonderful support thus afforded by what previously had been the weakest part of the pelvic floor can hardly appreciate from this brief description the effect produced.

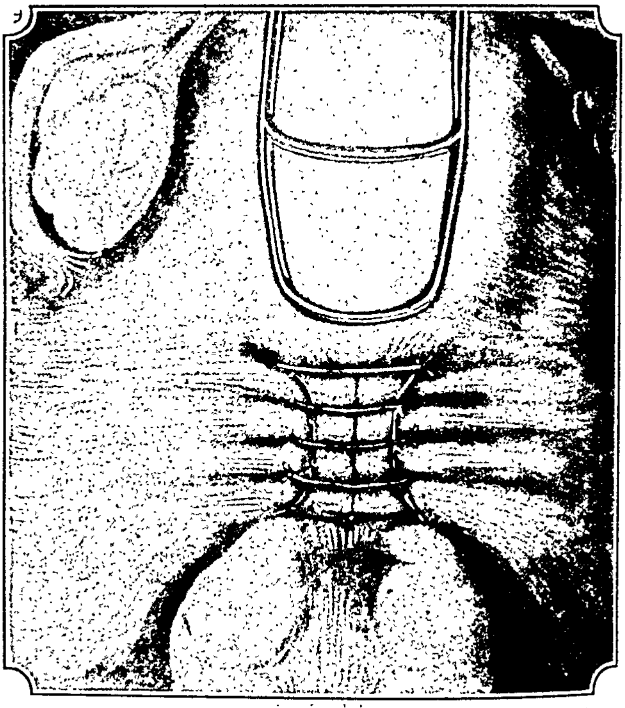

FIG. 5.—Final stages of author's method of reconstruction of posterior segment of pelvic floor.

Vaginal Operations.

Preparation of the vagina.—With regard to vaginal procedures, the first important point is the question of the preparation of the parts concerned for operation. I need hardly say that failure to secure good results is due to sepsis, which seems to have been the chief cause of disaster in connexion with the interposition operation. It must be obvious to anyone that a prolapse, which causes exposure of the cervix and vaginal walls to the ordinary infections of the skin surface, requires special preparation before operative procedures are undertaken. No one to-day would venture to operate on a case in which there was vaginal or cervical ulceration from friction. The patient, in these circumstances, would always be put to bed and the vagina douched and lightly packed to secure healing. In non-ulcerative cases the usual practice appears to be to give a few douches—supposedly antiseptic—before operation. But I doubt whether any method other than that I am about to describe will sterilise the vagina. I have come to the conclusion that douching the vagina with a view to cleansing is not only inefficient but positively harmful. The lactic acid normally found there is washed away, and the weak antiseptic solutions used for douching do not form an effective substitute. The ineffectiveness of douching, of course, is partly due to the fact that only recently have we become possessed of an antiseptic of adequate bactericidal power, which will not at the same time poison the subject. We know well that mercury products are extremely dangerous, and that women have been poisoned simply by their absorption from the vagina; the same remark applies to the other antiseptics of real potency in strong solutions, with the exception of those that have found favour during the war. I have had no experience of the aniline dyes. I have used a strong hyperchlorite solution, and the most convenient of these is Milton fluid, now widely sold for various domestic purposes This fluid is a powerful hypertonic saline solution which contains 10 g of available chlorine to the litre But even with such an excellent solution which should be diluted to a strength of 1-10 to 1-30 with water, I do not think that douching would be really effectual we must remember that the vagina is full of crevices and that the fluid introduced in this way will not penetrate to all parts For this reason I now have the vagina packed tightly with gauze soaked in a solution of Milton fluid, and the pack is changed every 12 hours for several days before the operation By packing the vagina in this way we open out all the creases, and the solution, with which the gauze is saturated, is able to reach every part The importance of this procedure is very great, and I think that its adoption will help those who have had serious suppuration in the past—suppuration which I venture to think, has too often occurred after operation on those cases in which the vaginal walls and cervix have protruded from the vaginal orifice

Plastic vaginal operations —I have little to say here in regard to vaginal repair—that is to say, anterior and posterior colporrhaphy and perineorrhaphy—for the procedures are fully described in my text book on Gynæcology The essential points, however that I wish to emphasise are first, that the mere removal of a portion of the vaginal mucosa and the bringing together of the cut edges is, as I first showed in 1911[6] not good technique The vaginal walls, together with the underlying muscle fibres—in the case of the anterior vaginal wall the fibres concerned are largely those already described as forming the anterior part of the antero posterior pelvic sling—must be completely and widely separated from the base of the bladder in front and from the rectum behind The bladder wall and the wall of the rectum will then lie smoothly spread out beneath the scar rather than act as a potential hernia sac I believe, too, that my method of suturing the flaps composed of mucosa and muscle by means of a combined mattress and over stitch to bring large surfaces of the muscle and the edges of the mucosa together, thus forming a buttress throughout the length of the vaginal walls in front and behind, constitutes a most efficient method of forming plastic work on the vagina (Fig 6) I am glad to say that from time to time, I receive communications which inform me that operators are finding this the most satisfactory method of performing the vaginal procedures

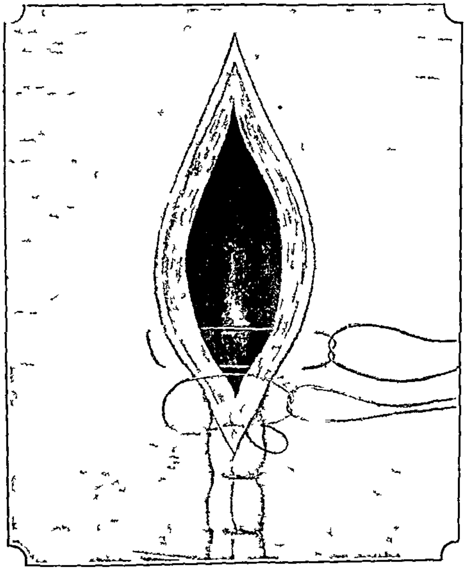

FIG 6—Author's mattress and overstitch for vaginal suture The overstitch may be taken through more than once if desired

I may, perhaps, be allowed therefore, to call special attention to this mattress and combined edge to edge sutures which I devised not only for suturing the vagina, but also for other conditions, such as for closing the uterine wound in Cæsarean section, after enucleation of fibroids excision of a portion of the uterus, and so on I think that those who try it will find it a useful detail of technique

The interposition operation —Next, I must briefly mention the interposition operation This procedure implies the fixation of the body of the uterus between the base of the bladder and the anterior vaginal wall with the underlying muscle fibres After the vaginal flaps have been stripped back from the base of the bladder and the cervix amputated the uterovesical pouch of the peritoneum is incised and the fundus of the uterus is delivered If it is too large, as is usually the case if the patient is not some years past the menopause, a large transverse wedge shaped piece of the fundus is excised together with the uterine ends of the tubes—an important detail if the patient although about at the menopause be still menstruating The V shaped opening is closed and the uterus placed in position behind the vaginal flaps Three sutures are then passed through the anterior surface of the uterus—the last should pass through the supravaginal cervix —and through the vaginal flaps as far out as possible on either side Anterior colporrhaphy is then performed and the sutures passing through the vaginal wall of the uterus are tied Posterior colporrhaphy and perineorrhaphy complete the operation

Post operative treatment of vagina —Equally as important as the preparatory local treatment in all cases in which plastic work on the vagina is performed is the post operative treatment Many trust to keeping the bowels confined for a week and to preserving dryness of the vulva both important details But what are we to do if blood collects in the vagina and decomposes? Formerly I employed for 24 hours a wick, or small pack, of ribbon gauze to collect the blood, which adhered to the gauze and was withdrawn with it, but I found that subsequent oozing not infrequently occurred Lavage of the vagina in the first few days after operation is a procedure which not infrequently especially in the hands of nurses leads to injury of the parts I have therefore been driven to devise a method of draining the vagina and of allowing it to be irrigated I use a double tube (Fig 7), which is placed in the vagina at the end of the operation and kept in position by means of sutures—one to each arm of the double tube, fixing it to the vaginal orifice It will be seen that in one arm there are no holes but that there is a slit like orifice at the end which will lie at the top of the vagina and that the other arm is perforated and has a large aperture at the end Irrigation with a solution of the Milton fluid is practised daily for four or more days This is effected by means of a funnel and tube attached by a glass junction to the longer arm which is always the one not perforated The solution is thus carried to the top of the vagina where it escapes from the slit like opening and irrigates the whole passage escaping eventually from the distal end of the shorter perforated arm This double tube has been of incalculable value to me It may, of course be employed elsewhere than in the vagina[7] The fact that almost every case in which plastic work only or an interposition of the uterus together with plastic work on the vagina has been performed has made an uninterrupted recovery, convinces me that the methods employed for purifying and draining the vagina have largely solved the outstanding questions concerning the dangers and disappointments which have undoubtedly followed extensive vaginal procedures for prolapse

FIG 7—Author's double tube for vaginal irrigation and drainage

Finally, I must add that it is useless to attempt plastic vaginal work unless it is possible to have the assistance of skilful nurses to whom I believe I have been largely indebted for the success of my cases

CONCLUSIONS

1 Operative treatment for prolapse is safe and effectual if satisfactory preparation and after treatment be adopted in conjunction with proper operative technique

2 No one procedure is suitable or satisfactory for every type of case

THE PELLAGRA OUTBREAK IN EGYPT.

II.—PELLAGRA AMONGST GERMAN PRISONERS OF WAR: OBSERVATIONS UPON THE FOOD FACTOR IN THE DISEASE.

BY J. I. ENRIGHT, B.A., M.D. N.U.I.,
HON. CAPTAIN, R.A.M.C. IN CHARGE OF MEDICAL DIVISION, PRISONERS OF WAR HOSPITAL, CAIRO.

A GLANCE at the illustrations which accompany this article will suffice to convince the most sceptical observer that I have made no mistake in diagnosis. I therefore do not propose to give a general account of pellagra, the symptoms of which are familiar to all interested in the subject. I may claim to have had an exceptional opportunity of becoming intimately acquainted with this disease. During my three years' association with the Prisoners of War Hospital in Egypt, I saw about two thousand clinical cases of this disease, and assisted or actually performed autopsies on nearly three hundred.

Though pellagra was common from 1916 onwards amongst the Turkish prisoners of war, the most outstanding occurrence, as shedding some light upon the ætiology of the disease, was the outbreak which I am about to describe amongst the German prisoners.

I have traced the various theories hitherto advanced up to the point where they break down, and there, for the moment at least, I must leave them.

Theories of Ætiology.

The literature of the ætiology of pellagra is voluminous, and for a detailed description thereof reference must be made to the many published works on the subject. I shall, however, briefly allude to, and discuss, the more current and popular theories. I am convinced that the disease is neither infectious nor contagious in the ordinary sense of the word. During the three years that I have been dealing with some thousands of pellagrins I have been struck by the fact that all the orderlies, including our own men, and Turks or Germans, in attendance on the patients, remained free from the disease. The character of the blood picture, the type of the temperature, and the post-mortem changes in the central nervous system, as revealed by Singer and Pollock, are evidence against the infective theory. Wilson, also, as a result of his investigations into the pathology of the disease, concludes that whatever the causation, it is not parasitic, but toxic. The theory of Alessandrini that pellagra is due to imbibing colloidal silica in water is so improbable that I need scarcely mention it. At all events, it is well known that the British troops never suffered from pellagra, though they drank the same silicious Nile water as the Egyptians, amongst whom the disease is widespread.

The theory proposed by Sambon that pellagra is due to a protozoon and is conveyed by a biting fly (*Simulium*), I have never found any reasons for believing, though superficially it is a very plausible one, and it has moreover attracted many adherents, among others, Stannus, who has studied pellagra extensively in Nyasaland. In support of the protozoal nature of the disease Sambon has advanced the mononuclear increase in the blood, the chronic course, the beneficial effects of arsenical treatment, and the rural distribution of the disease.

Personally I have never found an increase in the mononuclears in the blood of an uncomplicated case of pellagra, and other observers have confirmed this negative finding; but, as malaria occurs frequently in association with pellagra, it is quite evident that in these complicated cases an increase in mononuclear cells would and does occur. In its inorganic and organic forms I have used arsenic extensively in treatment and could not convince myself that it possesses any value even in alleviating the symptoms. In fact, my experience inclines me to think that it should be contra-indicated in the acute stages as being distinctly harmful. As regards the disease being confined merely to country dwellers, I can enumerate many cases who had resided in a large town for a long period prior to developing the well-known pellagrous symptoms. Besides, there are large districts in Egypt, the West Indies, and the United States where pellagra is prevalent in the absence of any biting flies. However, Jennings, King, Siler, Garrison, and MacNeal, though unanimous in excluding the *Simulium* as a factor in the causation, suggest that the stable-fly (*Stomoxys calcitrans*) may possibly play a part in the dissemination of the disease.

The Maize Theory.

Of all the theories adduced to explain the origin of pellagra, none has been more widely disputed and supported than the maize theory of Strambio, first initiated in 1786, and later elaborated by Lombroso. Wherever and whenever pellagra has appeared investigators have come forward to attribute its causation to maize. Much has been written about the various types of maize and its toxins. Complex organic compounds, extracted from damaged maize by artificial fermentation processes, toxins elaborated during its decomposition by various bacilli and fungi, the actual moulds and bacilli found on damaged cereal and even sound maize itself have all in turn been held responsible for the production of the disease. Moreover, it has been stated that pellagra did not appear in Europe until after the introduction of maize from the New World, and that the disease spread with its more general consumption. As it is outside the scope of this paper to deal minutely with the maize question, I should like to state my opinion that maize alone, though it may be a contributory factor, is not the sole one in the ætiology of pellagra. That is to say, it has no specific action, but may, by reason of the deficiency of its protein, act as a deficient or one-sided diet. It is now known that "zein," the maize protein, is lacking in tryptophane, which has been proved necessary for growth and the maintenance of life (Wilson). Devoto, Driscoll, Volpino, and Nivello were confirmed believers in the maize theory. The two latter observers stated even that they had proved experimentally to their own satisfaction that the pellagrous and those prone to the disease were hypersensitive to maize extracts. This reaction they regarded as pathognomonic and of great value in early diagnosis.

However, in view of the great difficulty of making early diagnosis and of the similarity of the disease to other skin affections, it is reasonable to suggest that pellagra existed, though unrecognised by the medical profession, in Europe long before the introduction of maize. The disease may formerly have been sporadic, and may have assumed epidemic proportions only after the advent of maize. The increase in its incidence may have been due, not so much to the greater consumption of maize as to the absence of other vital elements which were supplanted by maize in the dietary. In the terse words of Sandwith, pellagra might be caused "not by what a man eats but by what he fails to eat."

The Modern Conception of Pellagra.

The modern conception of pellagra is that it is a food-deficiency disease, closely allied to scurvy and beri-beri. Although at first sight no three more dissimilar diseases could be imagined, they are known to possess many features in common; their predisposing conditions and environment are more or less alike, and in all three the symptoms can be ameliorated by a more nutritious diet. Scurvy and pellagra have been found in frequent association, whilst œdema, often culminating in anasarca, is by no means an uncommon sequel of pellagra, thus forming a clinical picture closely resembling that of wet beri-beri. On reading the description of that disease in Manson's "Tropical Diseases," I was at first inclined to conclude that some of the cases were really pellagrous.

The experiments of Goldberger and his co-workers in his asylum and orphanage cases would seem to be convincing testimony that pellagra is a food-deficiency disease and that complete recovery is possible, in the early stages at all events, if a decided increase in the allowance of fresh animal meat is made and eggs and fresh milk are freely given. His actual production of the disease in previously healthy subjects who were submitted to a curtailed one sided diet over an extended period would seem to leave little room for doubt as to the causation.

Sandwith, in Egypt, always found that early cases of pellagra could be cured by admission to hospital and by an abundant mixed diet. My own experience among *Turkish cases of pellagra taught me that the early* cases offered the best chances for successful treatment In advanced cases the hopes of ultimate recovery are more remote, possibly because the balance of protein metabolism is disturbed in some mysterious way, so that no additional amount of protein in the curative diet can restore it to normal

When, in the latter months of 1918, the disease appeared among the German prisoners, my faith in the food deficiency theory, which had previously appeared satisfactory, began to become undermined, so that I was driven to the conclusion that other factors than diet were involved and that a "food deficiency' could not explain the origin of the disease in these men The Germans had lived apparently upon a varied dietary, ample both in quantity and quality for normal requirements

I now propose to describe the outbreak in detail, laying special stress upon the previous history of the case, both dietetic and medical, as well as the clinical details and the results of treatment

Details of the Outbreak

The total number of cases amongst the German prisoners of war was 65, of which I give details of 32 (Table I)

1 *Age incidence*—The ages of the patients ranged from 19 to 45 The distribution according to age was as follows 24 or under, 32, 30 to 25 (inclusive), 18, 31 to 40 (inclusive), 13, 41 to 45 (inclusive), 2 The period of greatest liability to attack was therefore that of adolescence This might have been expected from the fact that the outbreak occurred among soldiers, whose ages were restricted to certain limits It should, however, be noted that the youngest were chiefly affected

2 *Previous diseases*—The principal diseases from which the patients had suffered during the two years preceding the onset were the following Dysentery, 38, malaria, 45, malaria and dysentery, 27, diarrhœa or dysentery, 62 Only 3 of the cases had no previous history either of diarrhœa or dysentery Two had had symptoms of scurvy before the rash appeared There were also a few cases of paratyphoid fever, pneumonia, and bronchitis

3 *Date of capture*—The great majority of prisoners were captured either in September or early November, 1918 All, with two exceptions, were captured in Palestine, these two were taken prisoners in German East Africa in November, 1917 One of them arrived in Egypt in January, 1918, and was in Maadi prisoners of war camp, near Cairo, from that date until he contracted pellagra in February, 1919 The other came to Egypt in March, 1918 and developed the disease in April, 1919

4 *Residence before capture*—With the exception of the two cases already referred to, all were attached to the Turkish forces in Palestine The duration of their residence in the East varied from 2 to 24 months A prisoner who had a particularly bad attack of wet pellagra had been in Palestine only two months before his capture The majority of them were over five months there, as shown in Table I

5 *Residence in the East after capture*—Excepting a brief period spent in a stationary hospital or camp in Palestine or at Kantara whilst en route for Egypt the patients had remained during captivity either in Heliopolis or Maadi camps or No 2 Prisoners of War Hospital in Cairo Many who were admitted to the hospital directly after capture suffering from other illnesses, such as dysentery or malaria, were discharged to one of the camps only to return later to the hospital with pellagra The two German East African cases were in Maadi camp, Cairo, for 13 months prior to the onset of the rash The periods intervening from the date of capture to the appearance of the rash for each prisoner can be seen at a glance in Table I

6 *Diet before capture (in Palestine)*—The official German army ration for the German troops in Palestine, all picked and highly paid men, as given me by a sergeant major in charge of the supply department, is as follows —

750 g of bread, 453 g of fresh vegetables or 226½ g of beans *peas, lentils, rice or potatoes, 350 g of fresh meat* 30 g of sausage or cheese butter or jam, 25 g of coffee, 17 g of sugar

In order to control this statement each patient was asked to furnish me with a copy of his diet while in Palestine They confessed to having partaken of the following diet

Breakfast bread butter, dripping eggs bacon, fresh or tinned sausage coffee, sugar, marmalade Lunch fresh meat, potatoes, *fresh or dried* vegetables, or beans, peas lentils, rice or oats, fresh or tinned fruit Tea bread butter, dripping eggs, cheese, tinned or fresh meat or sausages, tea or coffee (some alcoholic drinks, especially beer)

This diet was substantially the same according to all the reports There were some minor differences Some said that occasionally they did not eat fresh fruit or vegetables *for a few days*, whilst others drank cocoa instead of tea or coffee They were unanimous, however, in saying that their food in Palestine was sufficient both in quantity and quality In fact, they all asserted they had been living on "the fat of the land"

TABLE I—*Details of 32 Cases of Pellagra amongst German Prisoners in Egypt.*

A = Period of residence in Palestine
B = Period of captivity before onset of rash
C = Period in hospital
D = On admission to hospital

Diet After Capture

The diet after capture seemed to me to be ample even for hard labour Its approximate value as reckoned in calories may be thus stated The diet after capture may be resolved into two factors (1) camp diet, and (2) hospital diet —

1 *Camp diet* (according to the Report of the Inquiry regarding the prevalence of pellagra among Turkish prisoners of war, Lelean and Boyd December 1918, p 61)

	Protein		Fat	Carbohydrate	Calories
	*B P V	Gross			
26/1/18 G R O 3462	63 5	95 2	29 77	340	2002
18/5/18 G R O 3838	54 7	90 3	28 81	351	2009
18 8 18 G R O 4385	58 3	92 7	33 47	341	2087
†Rations + canteen extras at Maadi Nov 18th	89 7	144 3	120 67	458	3580

*B P V = Biological protein value (normal B P V for working individual should be 40 Wilson) † P 17

As comment on these diets is unnecessary, I shall merely quote the opinion of the Pellagra Committee on the last one (Maadi):—

> "This (diet) is of interest in connexion with the fact that 2000 Germans remained wholly pellagra-free during two years' confinement alongside the Turks at Maadi non-labour camp, where many Turks became pellagrous under conditions presenting only one difference—viz., that of diet.
>
> "It is important to note that these Germans had apparently never been exposed to such a dietetic shortage as is associated with pellagra, and their augmented diet is both varied and extremely full for a non-labour community" (p. 18).

The first paragraph of this statement needs considerable revision, especially in view of the fact that the two Germans from German East Africa presumably consumed this diet daily for 13 months and then contracted pellagra. The second paragraph now reads as an anachronism; alternatively the findings of the Committee of Inquiry are out of date.

Hospital diet (No. 2 Prisoners of War).—As furnished by the contractor in charge of the catering:—

Ordinary diet.—Breakfast: Tea and milk, bread-and-butter, and porridge or boiled eggs (2) or omelettes, or curry and rice, or minced meat and rice. Lunch: Bread and pudding and mixed vegetable soup (thick), or pie, or stew, or meat rissoles. Tea: Bread and jam or butter, tea and milk and boiled eggs or omelettes, or stuffed tomatoes, or curry and rice, or minced meat and rice.

Milk diet.—Breakfast: Tea and milk, bread-and-butter, one pint of milk. Lunch: Bread-and-butter, milk and custard. Tea: Bread and jam or butter, tea and milk, and one pint of milk. Extras supplied: Chicken, fish, veal cutlets, raw meat, salad, eggs, bread-and-milk. (Alcoholic drinks supplied at the medical officer's discretion.) It was the invariable rule, when the patient's condition permitted, to add to the milk diet as extras chicken and two eggs.

To correct any source of error which might exist in the contractor's rendering of this diet, I asked a responsible German orderly, in charge of a German ward, to supply me with a copy of the various diets as actually served to the German prisoners in the hospital. His statement substantially verified the contractor's list. Only in one detail did it differ—viz., that tea was not supplied in the milk diet.

The above is an accurate account of the generous diets consumed for the period subsequent to their capture and prior to the onset of the pellagrous rash. The hospital diet is inserted for greater accuracy, as some patients spent but a short period there previous to the onset of the rash. However, the diet exclusively consumed by the majority during this interval was the camp diet.

Time, Place, and Mode of Onset.

In my opinion, the date of onset should be reckoned from the beginning of the last attack of diarrhœa or dysentery immediately preceding the first appearance of the rash; but, as previously stated, the disease can be only suspected in the prodromal stage. Consequently, the exact time of onset remains questionable until the characteristic eruption becomes apparent. For the sake of uniformity I have decided to estimate the date of onset by the first appearance of the rash.

Time of onset.—The date of the earliest onset, as far as my observation goes, was Jan. 10th, 1919. Two prisoners stated that about the beginning of December, 1918, they noticed a peeling of their hands. As they attributed this condition to the cold weather, they did not "report sick" and were not seen by a medical officer. In all probability the onset took place early in December, 1918. The monthly incidence was as follows: January, 13 cases; February, 11 cases; March, 12 cases; April, 14 cases; May, 4 cases; June, 2 cases; July, 7 cases.

Place of onset.—Of the 65 cases, 25 were actually patients in the hospital when the rash appeared. These were admitted suffering apparently from other diseases. On admission 8 had diarrhœa, 9 had dysentery, 2 wounds, and 1 pneumonia. Some were complicated by malaria or by broncho-pneumonia. All had diarrhœa to a variable extent. Of the remaining 40, 32 had been treated in the hospital for diarrhœa, dysentery, or malaria for some considerable time prior to admission for pellagra. They were either in Heliopolis or in Maadi camps when the diagnosis of pellagra was first made.

It must be noted that the Germans most emphatically declared that they had never seen the disease among themselves before capture, though they recognised it amongst the Turks. All these cases must therefore be regarded as primary attacks. My own experience of the accuracy of the German statements and their intelligence with regard to their previous illnesses, the mildness of many of the cases, and the generally successful response to treatment tended to confirm this opinion.

Case incidence.—I am not in a position to state the exact case incidence, as I do not know the total number of German prisoners captured in the final offensive against the Turks. However, I think it did not exceed 1 per cent. The total number of German prisoners was probably between 7000 and 8000.

Condition on admission.—As I have already stated, 25 were in hospital when the rash appeared. These cases were very interesting, as many of them were suspected and put under observation during the prodromal stage. On admission they were weak, anæmic, and emaciated. Some were so exhausted that they had not enough energy to dress themselves, and so debilitated that they frequently staggered when walking. One patient, who presented a particularly miserable and emaciated appearance, told me that previous to this illness he was always healthy and strong; in fact, he was a gymnast by profession. Many of the others were equally emphatic about their previous history. A few, however, were well nourished and expressed themselves as feeling quite well, except for the slight local irritation caused by the eruption.

The weights of all patients were recorded on admission (see Table I.), and are instructive when contrasted with the weights of the same individuals at the end of the period of observation.
